RESERVED	DETECTEDENDOFPGM	DETECTEDSTOPSEQ	ENDPGMERROR	OPCODEERROR	WRITEREGERROR	EXECSTATE									PC									CYCLEDCOUNT							

Bits	Field Name	Description	Type	Reset
31	RESERVED	Read returns 0.	R	0x0
30	DETECTEDENDOFPGM	This bit is set to '1' when, in Debug mode, an EndPgm() instruction or the last instruction of the program buffer has been reached and it is not a LoadInstBuf() instruction. This bit is cleared by a StartSeq() command when in INITIALIZED or COMPLETED state.	R	0x0
29	DETECTEDSTOPSEQ	This bit is set to '1' when a StopSeq() has been issued and the iME is in Halted state. Execution of StopSeq() is postponed to the time when the CPU gets out of the Halted state. This bit is cleared when the StopSeq() command is effectively executed.	R	0x0
28	ENDPGMERROR	This bit is set to '1' when the last instruction of the program buffer is reached and no EndPgm() or LoadInstBuf() instruction have been detected in the program buffer. This bit is cleared by a StartSeq() command when in INITIALIZED or COMPLETED state.	R	0x0
27	OPCODEERROR	This bit is set to '1' when an unknown opcode is decoded from the main program. The following instruction of the sequence is then executed. This bit is cleared by a StartSeq() command when in INITIALIZED or COMPLETED state.	R	0x0
26	WRITEREGERROR	This bit is set to '1' when attempting to write an internal register through an OCP write, while in EXECUTING state. This bit is cleared by a StartSeq() command when in INITIALIZED or COMPLETED state.	R	0x0
25:24	EXECSTATE	Execution States: 00 = Initialized, 10 = Executing, 01 = Halted, 11 = Completed.	R	0x0
23:16	PC	Number of instruction currently executing. Bit #7 is always 0 (PC values range from 0x00 to 0x7f)	R	0x00
15:0	CYCLECOUNT	Total number of cycles executed.	R	0x0000

Camera Image Signal Processor

This chapter describes the camera image signal processor (ISP2P) in the device. ISP2P is backward compatible with ISP2 that is in the legacy device. To facilitate reading in this chapter, ISP2P will be referred to as ISP.

NOTE: Some of the information in this chapter is © 2005-2008 MIPI Alliance, Inc. All rights reserved.

MIPI Alliance Member Confidential.

All rights reserved. This material is reprinted with the permission of the MIPI Alliance, Inc. No part(s) of this document may be disclosed, reproduced or used for any purpose other than as needed to support the use of the products of TI.

See [Device 37xx MIPI Disclaimer](#) for details.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#), and the device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

6.4 Camera ISP Functional Description	1148
6.5 Camera ISP Basic Programming Model	1238
6.6 Camera ISP Register Manual	1296

6.1 Camera ISP Overview

The camera ISP is a key component for imaging and video applications such as video preview, video record, and still-image capture with or without digital zooming.

The camera ISP provides the system interface and the processing capability to connect RAW image-sensor modules to the device.

The camera ISP implements three receivers which are named CSI2A, CSI1/CCP2B, and CSI2C. The CSI2A and CSI2C are MIPI® D-PHY CSI2 compatible. The CCP2B (compact camera port) is MIPI D-PHY CSI1 compatible if used in CSI1 mode. Moreover, on the outside boundaries of camera ISP before the mentioned above receivers, are located two MIPI D-PHY CSI2 compliant physical layers (CSIPHY1 and CSIPHY2). The two PHYs are MIPI CSI2 and MIPI CSI1/SMIA CCP2 compliant. Their purpose is to act as a physical connection between the outside pins for connecting external sensors and the internal receivers. By configuring the outside PHYs and feeding the receivers, the camera ISP supports up to two simultaneous pixel flows from external sensors. Only one of the data flow can use the Video processing hardware while the other must go to memory.

Figure 6-1 shows the camera ISP overview diagram.

Figure 6-1. Camera ISP Overview Diagram

- (1) The mode for each PHY can be selected from CSI2, CSI1/CCP2B, and GPI at SCM.CONTROL_CAMERA_PHY_CTRL register. It can also control the connection between one of the PHY's and CSI1/CCP2B receiver via multiplexing.
- (2) There is no top-level muxmode (padconf SCM register) control bit for the different camera modes supported by the interfaces. If one or another of the interfaces is enabled, then the camera input signals will be automatically routed to the corresponding ISP receiver depending on the PHY operating mode settings (SCM.CONTROL_CAMERA_PHY_CTRL register).

NOTE: For information about initializing and configuring the CSIPHY, see [Section 6.5.2, Programming the CSI1/CCP2B or CSI2 Receiver Associated PHY](#).

6.1.1 Camera ISP Features

The camera ISP can support the following features:

- **Image sensor:**
 - Interface with various image sensors:
 - R, G, B primary colors
 - Ye, Cy, Mg, G complementary colors
 - Support for electronic rolling shutter (ERS) and global-release reset shutters
- **CSI1/CCP2B serial interface:** The CSI1/CCP2B receiver is compatible with the SMIA CCP2 specification and the MIPI CSI1 specification. It supports the following features:
 - Image from sensor
 - Transfer of pixels and data received by the associated PHY to system memory or to the Video processing hardware
 - Unidirectional data link
 - 1D and 2D addressing mode
 - Maximum data rate of up to 650 Mbps in CCP2 mode and 208 Mbps in CSI1 mode
 - False synchronization code protection
 - Ping-pong mechanism for double-buffering
 - Support of RGB, RAW, YUV, and JPEG formats
 - DPCM decompression supported
 - Image read from memory
 - RAW formats supported
- **Two MIPI CSI2 serial interfaces:** The camera ISP implements two MIPI CSI2 serial interface receivers (CSI2A and CSI2C). The CSI2 receivers enables data transfer at up to 2Gbps. It is based on the MIPI CSI2 Specification 1.0.
 - Transfer pixels and data received by the CSIPHY1 or CSIPHY2 to the system memory or to the Video processing hardware
 - Uses unidirectional data link
 - Supports up to two data-configurable links, in addition to the clock signaling
 - Maximum data rate of up to 1000M bps per data lane
 - Data merger configuration for CSI2A two data lanes and CSI2C one data lane
 - Error detection and correction by the protocol engine
 - DMA engine integrated with dedicated FIFO
 - Streaming 1-D and 2-D addressing mode (rotation is not supported by the 2D mode)
 - Ping-pong mechanism for double buffering
 - Burst support
 - RAW frame transcoding. Including DPCM and A-law compression
 - JPEG support for unknown length transfer
 - RGB, RAW, and YUV formats supported
 - Storage in progressive mode for interlaced stream (using line numbering)
 - Conversion of the RGB formats
 - Configuration of the associated PHY through Serial Configuration Port (SCP)
 - Fully configurable interface of PHY: position of the clock and data and order of +/- differential signals for each pair.
 - Low power mode using PRCM protocols
- **Parallel interface:** The camera parallel interface (CPI) supports two modes:
 - **SYNC mode:** In this mode, the image-sensor module provides horizontal and vertical synchronization signals to the parallel interface, along with the pixel clock. This mode works with 8-,

10-, 11-, and 12-bit data (if using CCDC inside the Video processing hardware above 10 bit data must be internally converted to 10 bit by the Bridge lane shifter). SYNC mode supports progressive and interlaced image-sensor modules.

- **ITU mode:** In this mode, the image-sensor module provides an ITU-R BT 656-compatible data stream. The horizontal and vertical synchronization signals are not provided to the interface. Instead, the data stream embeds start-of-active video (SAV) and end-of-active video (EAV) synchronization code. This mode works in 8- and 10-bit configurations.
- **Video processing hardware:** The Video processing hardware removes the need for expensive camera modules to perform processing functions. It consists of parts: front end and back end:
 - **Video processing front end (VPFE):** Performs signal-processing operations on RAW image input data. The output data can go directly to memory for software processing, or to the video-processing back end for further processing. The Video processing front end is supported by the CCDC module. Signal-processing operations include:
 - Optical clamping
 - Black-level compensation
 - Look-up table (LUT) based faulty pixel correction
 - 2D lens-shading compensation
 - Data formatter
 - Output formatter

NOTE: Up to 12-bit data at 83 MHz can be transferred from the video port to the ISP submodules. The video processing ISP can treat one pixel every two interconnect clock cycles.

- **Video processing back end (VPBE):** Performs signal-processing operations on RAW image input data. Outputs YCbCr 4:2:2 data.
 - **Preview module:** Signal-processing operations include:
 - A-law decompression: transforms non-linear 8-bit data to 10-bit linear data. The CCDC module can perform A-law compression
 - Noise reduction and faulty pixel correction
 - Dark frame capture and subtraction
 - Horizontal median filter
 - Programmable filter: 3x3 kernel of the same color
 - Couple faulty pixel correction
 - Digital gain
 - White balance
 - Programmable color filter array (CFA) interpolation: 5x5 kernel
 - Black adjustment
 - Programmable color correction (RGB to RGB)
 - Programmable gamma correction: 1024 entries for each color
 - Programmable color conversion (RGB to YCbCr 4:4:4)
 - Color subsampling (YCbCr 4:4:4 to YCbCr 4:2:2)
 - Luminance enhancement (non-linear), chrominance suppression and offsetThe preview module can also work from memory to memory.
 - **Resizer module:** Performs on-the-fly upsampling (up to x4) and downsampling (down to x0.25) of YCbCr 4:2:2 data by applying high-quality horizontal and vertical filters. The horizontal and vertical resizer ratios are independent. Applicable ratios are 256/N, with N ranging from 64 to 1024. This feature enables digital zooming (upsampling) and video preview (downsampling).The resizer module can also work from memory to memory. Higher or lower ratios can be obtained by combining on-the-fly resizing followed by memory-to-memory resizing.

- **Statistic collection modules (SCM):** The host CPU uses statistics to adjust various parameters for processing image data.
 - **3A metrics:** Collects on-the-fly RAW image data metrics, which are required to perform the control loops for auto white balance (AWB), auto exposure (AE), and autofocus (AF). The MPU subsystem typically uses data metrics to adjust various parameters for processing image data.
 - **Histogram:** Performs on-the-fly pixel binning of RAW image, based on color value ranges and regions. Supports up to 4 regions and up to 256 bins per color. The MPU subsystem typically uses the histogram with 3A metrics to adjust various parameters for processing image data.
The histogram module can also work from memory to memory.
- **Central-resource shared buffer logic (SBL):** Buffers and schedules memory accesses requested by camera ISP modules
- **Circular buffer:** Prevents storage of full image frames in memory when data must be postprocessed and/or preprocessed by software
- **Memory management unit (MMU):** Manages virtual-to-physical address translation for external addresses and solves the memory-fragmentation issue. Enables the camera driver to dynamically allocate and deallocate memory; the MMU handles memory fragmentation.
- **Clock generator:** Generates two independent clocks that can be used by two external image sensors
- **Timing control:**
 - Generation clocks passed to the clock generator
 - Generation of signals for strobe flash, mechanical shutter, and global reset. Support for red-eye removal.
- **Open core protocol (OCP) compliant:**
 - One 64-bit master interface connected to L3
 - One 32-bit slave interface connected to L4

6.2 Camera ISP Environment

6.2.1 Camera ISP Functions

[Table 6-1](#) describes the camera ISP functions and the corresponding application fields.

Table 6-1. Camera ISP Functions

Function	Description
Parallel interface in generic configuration (SYNC mode)	The camera ISP supports up to 12 bits (If CCDC used inside the Video processing hardware, data must be converted to 10 bit by the Bridge lane shifter). The camera ISP can interface with RAW interlaced or progressive image sensors using RGB or complementary color mosaic filters.
Parallel interface in ITU-R BT.656 configuration (ITU mode)	The camera ISP can extract the synchronization signal start of active video and end of active video from the ITU-R BT.656 bit stream. 8-bit and 10-bit modes are supported.
CSI1 / CCP2B serial interface configuration (serial mode)	The camera ISP supports one CCP2B serial interface, compatible MIPI CSI1.
MIPI CSI2 serial interfaces (CSI2A and CSI2C) configuration (serial mode)	The camera ISP supports two MIPI CSI2 serial interface.

NOTE: The two CSI2A and CSI2C receivers and the CSI1/CCP2B receiver can be active simultaneously. Either the CSIPHY1 or CSIPHY2 data can go through the selected interfaces to the video-processing hardware, while the other data are sent directly to memory by the receiver selected.

The parallel interface is limited to 10 bits when used simultaneously with the CSI2A or CSI2C receivers.

The parallel interface cannot be used simultaneously with the CSI1/CCP2B receiver.

6.2.3 Camera ISP Connectivity Schemes

The cam_d[9:6] implements the CSIPHY1. The cam_d[1:0] implements the CSIPHY2. Moreover, the PHY's can be configured in GPI, CCP, or D-PHY modes from the control module and the SCM.CONTROL_CAMERA_PHY_CTRL control module register. Besides the mode set, from the SCM.CONTROL_CAMERA_PHY_CTRL[4] CSI1_RX_sel sets which PHY will be hooked to the CSI1/ CCP2B receiver of the ISP. Some initialization and pad configuration must also be done. For information about initializing and configuring the CSIPHY, see [Section 6.5.2, Programming the CSI1/CCP2B or CSI2 Receiver Associated PHY](#).

- In GPI mode, the PHY can be connected to a parallel camera (CAM_D[1:0] in CSIPHY1 and CAM_D[9:6] in CSIPHY2)
- In CCP mode, the PHY can be connected to a CCPV2 camera (strobe/data pairs) or a CSI1 camera (clock/data pairs)
- In D-PHY mode, the PHY can be connected to a CSI2 camera (2 or 1 data lane in CSIPHY1 and 1 data lane only in CSIPHY2)

Table 6-3. Camera ISP Connectivity Schemes

Receiver	Scheme 1	Scheme 2	Scheme 3	Scheme 4	Scheme 5	Scheme 6

NOTE:

- If the parallel camera sensor is the only sensor connected to one CSIPHY, the SCM.CONTROL_CAMERA0_PHY_CAMMOD and SCM.CONTROL_CAMERA1_PHY_CAMMOD bits must be set to 0x11 (that is, GPI mode).
 - If the parallel camera sensor and the other camera sensor (CCP2 or CSI2) are connected to the same CSIPHY, the CONTROL_CAMERA x _PHY_CAMMOD bit must be set for CCP2 or CSI2 mode, respectively, (even if only one pair is used as GPI for CPI mode). In that case, the corresponding [CSI2_COMPLEXIO_CFG1](#).DAT Ax _POSITION bit must be set to 0x0 for the lane used in GPI mode.
-

6.2.4 Camera ISP Protocols and Data Formats

6.2.4.1 Camera ISP Parallel Generic Configuration Protocol and Data Format (8, 10, 11, 12 Bits)

The SYNC mode implements a generic parallel interface with the image sensor. The SYNC mode supports 8 to 12-bit-wide data signals.

In this configuration, no assumptions are made on the data format of pixels, but the dynamic range is limited to 8-, 10-, 12 bit (data can be pure luminance for black and white sensor, RGB444, Bayer RGB, etc.). The pixel data is presented on cam_d, where one pixel is sampled for every cam_pclk rising edge (or falling edge, depending on the configuration of cam_pclk polarity). For more information, see [Section 6.4](#).

Additional pixel times between rows represent blanking periods. Active pixels are identified by a combination of two additional timing signals: horizontal synchronization (cam_hs) and vertical synchronization (cam_vs). During the image-sensor readout, these signals define when a row of valid data begins and ends, and when a frame starts and ends.

NOTE: For correct operation, the clock cam_pclk must run during blanking periods (cam_hs and cam_vs inactive). cam_pclk must start before sending cam_d and start cam_vs and cam_hs.

[Figure 6-2](#) and [Figure 6-3](#) show the frame and data timing, respectively, based on synchronization signals in the parallel No BT configuration.

Figure 6-2. Camera ISP Synchronization Signals and Frame Timing in SYNC Mode

Figure 6-3. Camera ISP Synchronization Signals and Data Timing in SYNC Mode

NOTE: The pixel clock can be gated to qualify valid pixels. It can also be gated during blanking periods to reduce power consumption. However, at least 4 clock pulses are required before sending active image data and synchronization information; 8 clock pulses are required after the end of active video. Extra-clock pulses are allowed but not required during the line blanking periods.

[Figure 6-4](#) shows the timing diagram of the SYNC mode clock gating.

Figure 6-4. Camera ISP SYNC Mode Clock Gating

camisp-132

6.2.4.2 Camera ISP Parallel Generic Configuration: JPEG Sensor Connection on the Parallel Interface

Some camera modules integrate an image-signal processor (ISP) and a JPEG encoder. The CCDC can interface with these camera modules and transfer the received JPEG stream to memory.

To use this mode, set the **ISP_CTRL [30]** JPEG_FLUSH bit.

Figure 6-5 shows timing diagrams for an JPEG stream.

Figure 6-5. Camera ISP JPEG Stream Timing Diagrams

CAUTION

The bridge cannot be used for JPEG sensor connections.

6.2.4.3 Camera ISP ITU-R BT.656 Protocol and Data Formats (8, 10 Bits)

CAUTION

The ITU-R BT.656 mode cannot be used when the bridge is enabled.

The camera ISP interface supports data in ITU-R BT.656 format.

The ITU-R BT.656 standard specifies a method of transferring YUV422 data over an 8- or 10-bit video interface.

Figure 6-6 shows the data timing diagram with embedded synchronization signal.

Figure 6-6. Camera ISP Data Timing With Embedded Synchronization Signals (8-Bit Case)

In BT.656, the data words (8- or 10-bit) in which the eight most-significant bits (MSBs) are all set to 1, or all set to 0 are reserved. Only 254 of the possible 256 8-bit word values, and 1016 of the possible 1024 10-bit word values represent signal values.

The data is multiplexed in the following order: Cb0 Y0 Cr0 Y1 Cb2 Y2 Cr2 Y3, etc., where the byte sequence Cb2n Y2n Cr2n refers to interleaved luminance and chroma samples and the following byte Y2n + 1 corresponds to the next luminance sample.

The BT.656 protocol uses unique timing reference signals embedded in the video stream. The synchronization signals cam_hs and cam_vs are not needed. This reduces the number of wires required for a BT.656 video interface.

There are two timing reference codes: The start of active video (SAV) reference code precedes each video data block, and the end of active video (EAV) follows each video data block. Each timing reference signal consists of a 4-byte sequence in the following hexadecimal format: **FF 00 00 XY**. The first 3 bytes are a fixed preamble (see the ITU-R BT.656 specification). The fourth byte (XY) contains information defining field identification (F), blanking (V), and SAV/EAV information (H), and 4 parity bits calculated as a function of F, V, and H (see the ITU-R BT.656 specification).

Table 6-4 lists the video timing reference codes for SAV and EAV.

Table 6-4. Camera ISP Video Timing Reference Codes for SAV and EAV

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

Table 6-5 contains a description of the F, V, and H signals.

Table 6-5. Camera ISP F, V, H Signal Descriptions

Signal	Value	Command
F	0	Field 1
	1	Field 2
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

The resulting Hamming distance between any two code words is four, allowing two error detections and one error correction. To enable or disable the error-correcting capability, configure the [CCDC_REC656IF \[1\]](#) ECCFVH bit.

NOTE: The 2-bit errors are detected, but not flagged or corrected. Errors of more than 2 bits are not corrected or flagged.

[Table 6-6](#) lists the F, V, and H protection (error-correction) bits.

Table 6-6. Camera ISP F, V, H Protection (Error-Correction) Bits

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

When operating in CCIR-656 mode, data is stored in SDRAM according to the format shown in [Table 6-7](#) when [CCDC_SYN_MODE \[11\]](#) PACK8 is enabled.

Table 6-7. Camera ISP BT.656 Mode Data Format in SDRAM

8 bit x 4	Pixel3 (Y1/Cr0)	Pixel2 (Cr0/Y1)	Pixel1 (Y0/Cb0)	Pixel0 (Cb0/Y0)
	Bit 31			Bit 0

NOTE: The CCDC outputs the XY code in the SAV and EAV into memory. To eliminate this, users must set the SPH register field to +1. In addition, the NPH register field must be set to accurately represent the number of active pixels.

6.2.4.4 Camera ISP CSI1/CCP2 Protocol and Data Formats

The CSI1/CCP2B receiver supports two protocols:

- MIPI CSI1 protocol
- CCP2 protocol

The MIPI CSI1 protocol is compatible with the CCP2 protocol with the following constraints:

- Class 0 CCP2 sensors are used: Data/clock
- No RAW6 or RAW7 data types
- No CRC code generation
- Only one logical channel: Channel 0
- No DPCM

This section describes CSI1/CCP2B protocol and data formats. [Table 6-8](#) describes the I/O for serial interface CSI1/CCP2B.

Moreover, the CSI1/CCP2B receiver is a serial interface to an image sensor. Data is taken from pins and through the configured associated PHY taken to the receiver (for information about initializing and configuring the CSIPHY, see [Section 6.5.2.2, Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver](#)). The receiver on its side, can send data to the Video processing hardware or memory.

The CSI1/CCP2B receiver interface has several image-data operating modes, summarized in [Table 6-8](#).

Table 6-8. Camera ISP CSI1/CCP2B Image Data Operating Modes and Alignment Constraints

<u>CCP2_LCx_CTRL[7:3]</u> Format	CCP2B Data Format	OCP Bits per Pixel (bpp) (when sending data to memory, N/A when sending to VP)	Width Constraint: Must Be a Multiple of n Pixels	Storage Increase Versus Packed	2D Mode Availability ⁽¹⁾	Comments

0x1D	JPEG, 8-bit data + FSP	N/A	N/A	N/A	No	
0x1E	RAW10 - RAW8	8	16	20%	No	Data right shift

NOTE:

- EXP8 = Data expansion to 8 bits, padding with zeros
- EXP16 = Data expansion to 16 bits, padding with alpha or zeros
CCP2_LCx_CTRL [15:8] ALPHA can be used to set an alpha value.
For RGB444 + EXP16:
 - data_out[31:28] = ALPHA[3:0] and data_out[27:16] = RGB444
 - data_out[15:12] = ALPHA[3:0] and data_out[11:0] = RGB444
- EXP32 = Data expansion to 32 bits, padding with alpha
CCP2_LCx_CTRL [15:8] ALPHA can be used to set an alpha value.
For RGB888 + EXP32: data_out[31:24] = ALPHA[7:0] and data_out[23:0] = RGB888
- FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
- VP = Output to the video processing hardware is enabled. The programmer must ensure that only one logical channel is enabled to the Video processing hardware. The behavior of the video processing hardware is unpredictable if several logical channels to it are enabled simultaneously.

The preamble 0xFF0000 is fixed by construction and must not be modified. However, the CSI1/CCP2B receiver programming model allows the synchronization code identifier to be overwritten: bits 0 to 3.

Every code is transmitted bytewise, least-significant bit (LSB) first. For example, the code 0xFF00:0002 transmitted from the image sensor corresponds to the following bitstream: 11111111 - 00000000 - 00000000 - 01000000. Every default code starts with a set of eight 1s and sixteen 0s that are never received in pixel data. This means that content having eight 1s and sixteen 0s is not allowed. [Figure 6-7](#) shows an example of 0xFF00 0002 transmission.

Figure 6-7. Camera ISP Example of 0xFF00 0002 Transmission

Every code is transmitted bytewise, LSB first.
Example: code 0xFF00:0002

6.2.4.4.1 Camera ISP CSI1/CCP2 Pixel Data Format

This section summarizes how the CSI1/CCP2B pixel data formats are transmitted over the serial interface and how the pixels are reconstructed, stored in memory, or passed to the video port.

The CSI1/CCP2B receiver can cope with all data formats if the data line length sent through the associated PHY is a multiple of 32 bits. This condition is required for the CSI1/CCP2B receiver to work correctly.

However, some data formats impose stronger line-length constraints to correctly finish pixel reconstruction at the end of the lines. If the additional constraints are not respected:

- Only the last reconstructed pixels in every line are erroneous. The missing bits are replaced with 0s to perform pixel reconstruction.
 - The FW_IRQ interrupt is triggered.

6.2.4.4.1.1 Camera ISP CSI1/CCP2 YUV Pixel Data Formats

The YUV422 data format can be stored to memory in little- or big-endian format. The line length sent through the associated PHY must be a multiple of 32 bits.

YUV422 data format can also be sent to the video port.

YUV422 + VP is used to output RAW8 data to the video port: YUV422 + VP is equivalent to RAW8 + VP. [Figure 6-8](#) and [Figure 6-9](#) show big-endian and little-endian YUV422 format, respectively.

Figure 6-8. Camera ISP CSI1/CCP2 YUV422 Big Endian

camisp-182

The line length sent through the associated configured PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 3×32 bits and the number of lines is even to correctly finish the pixel reconstruction.

The line structure is different for odd and even lines. Odd lines transport the U component, while even lines contain the V component. This is shown in Figure 6-10.

Figure 6-10. Camera ISP CSI1/CCP2 YUV420

6.2.4.4.1.2 Camera ISP CSI1/CCP2 RGB Pixel Data Formats

RGB888 data format can be output to memory in two formats: with no data expansion and with data expansion.

If data expansion is used, the value of the 8 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the associated PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 3 x 32 bits to correctly finish pixel reconstruction.

Figure 6-11 shows an example of RGB888 format.

Figure 6-11. Camera ISP CSI1/CCP2 RGB888

Receiver

camisp-184

 For RGB565, the line length sent through the associated PHY is a multiple of 32 bits (see [Figure 6-12](#)).

Figure 6-12. Camera ISP CSI1/CCP2 RGB565

RGB565 Line width must be a multiple of one 32-bit word.

RGB444 data format is output to memory with data expansion. If data expansion is used, the value of the 4 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the associated PHY is a multiple of 32 bits (see [Figure 6-13](#)).

Figure 6-13. Camera ISP CSI1/CCP2 RGB444

6.2.4.4.1.3 Camera ISP CSI1/CCP2 RAW Bayer RGB Pixel Data Formats

6.2.4.4.1.3.1 Camera ISP CSI1/CCP2 RAW6 (CCP2 Only)

RAW6 data format can be output to memory in two formats: with no data expansion and with data expansion.

The line length sent through the associated PHY is a multiple of 32 bits. Furthermore, the line is a multiple of 3×32 bits to correctly finish pixel reconstruction (the lowest common multiple of 32 and 6 is 96; that is 3×32 bits).

Figure 6-14 shows RAW6 format.

NOTE: The RAW6 data format do not apply to the MIPI CSI1 compatible mode.

Figure 6-14. Camera ISP CSI1/CCP2 RAW 6

6.2.4.4.1.3.2 Camera ISP CSI1/CCP2 RAW7 (CCP2 Only)

RAW7 data format can be output to memory in two formats: with no data expansion and with data expansion.

The line length sent through the associated PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 7×32 bits to correctly finish the pixel reconstruction (the lowest common multiple of 32 and 7 is 224; that is, 7×32 bits).

Figure 6-15 shows RAW7 format.

NOTE: The RAW7 data format do not apply to the MIPI CSI1 compatible mode.

Figure 6-15. Camera ISP CSI1/CCP2 RAW 7

6.2.4.4.1.3.3 Camera ISP CSI1/CCP2 RAW8

RAW8 data format can be output to memory in two formats: with no data expansion and with data expansion.

The line length sent through the associated PHY is a multiple of 32 bits.

Figure 6-16 shows RAW8 format.

NOTE:

- Use RAW8 data format to output RAW6 and RAW7 data formats to memory.
 - Use YUV422 + VP to output RAW8 data to the video port: YUV422 + VP is equivalent to RAW8 + VP.
-

camisp-191

6.2.4.4.1.4 Camera ISP CSI1/CCP2 JPEG8 Pixel Data Formats

The line length sent through the associated PHY is a multiple of 32 bits. The false synchronization protection (FSP) code insertion on the transmitter side automatically ensures this line length. It is impossible to know in advance the size of a compressed stream. [Figure 6-19](#) shows JPEG8 and JPEG8 FSP format.

Figure 6-19. Camera ISP CSI1/CCP2 JPEG8 and JPEG8 FSP

In JPEG8 mode, the JPEG encoder on the sensor side must avoid generating data equal to the synchronization code and must deliver a synchronization-code-free bitstream.

In JPEG8 FSP mode, the bitstream is a standard JPEG8 bitstream in which byte-stuffing is used to differentiate synchronization code from original data with the same value. Thus, the JPEG encoder can generate a standard bitstream, and a postprocessing stage (FSP encoder) is used to highlight natural bitstream data equal to synchronization codes, so that the other end can discard the false synchronization codes.

FSP decoding is performed for byte-aligned data and occurs after the frame-start synchronization code is received. If the byte $n = 0x0$, the FSP decoder looks for bytes 1 and 2. If the bytes are equal to an illegal combination (synchronization codes), the byte $0xA5$ that comes after (byte $n + 1$) is removed from the bitstream.

The $0xA5$ padding bytes at the end of the frame are also removed by FSP decoding so that padding does not generate additional data in the FIFO. FSP decoding is then transparent to the software.

Normally, the module detects the illegal combination and then the $0xA5$. When the $0xA5$ is corrupted or replaced by another code, the value is automatically removed from the bitstream and an interrupt is generated to signal that the code is corrupt and therefore the received data are suspicious. If the line is too noisy for FSP decoding, it is better to configure the subsystem in JPEG8 and use software postprocessing.

6.2.4.5 Camera ISP CSI2 Protocol and Data Format

NOTE: The two CSI2 receivers (CSI2A and CSI2C) support MIPI CSI2.

6.2.4.5.1 Camera ISP CSI2 Lane Merger

The layer consists of lane merger logic to merge the incoming serial stream into a byte stream. The bits are sent with the LSB first. The order of the lanes at the CSI2 receiver core depends on the lane configuration.

The number of lanes and their configuration can be changed only in ULPM or when all data lanes are in off mode.

The lane merger can merge up to four lanes into a single byte stream.

In case of a single lane, the lane merger is not used to merge byte streams.

[Figure 6-20](#) and [Figure 6-21](#) show an example of byte position into each serial link for 1 and 2 data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to receive and the number of lanes.

Figure 6-20. Camera ISP CSI2 Two Data-Lane Merger Configuration

The number of bytes, N, is an integer multiple of the number of lanes (2).

The number of bytes, N, is not an integer multiple of the number of lanes (2).

6.2.4.5.2 Camera ISP CSI2 Protocol Layer

The low-level protocol (LLP) is a byte-oriented protocol from the lane merger layer. It supports short and long packet formats.

The CSI2 protocol layer defines how image-sensor data is transported onto the physical layer.

The feature set of the protocol layer implemented by the CSI2 receiver is:

- Transport of arbitrary data (payload-independent)
- 8-bit word size
- Support for up to four interleaved virtual channels on the same link
- Special packets for frame-start, frame-end, line-start, and line-end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- Error-correction code (ECC) for 1-bit error correction or 2-bit error detection in the header
- 16-bit checksum code for payload error detection

Figure 6-22 shows the CSI2 protocol layer with short and long packets.

Figure 6-22. Camera ISP CSI2 Protocol Layer With Short and Long Packets

Two packets are always separated from each other with a sequence of a ULPM, an ET, and an ST.

6.2.4.5.2.1 Camera ISP CSI2 Short Packet

A short packet is identified by data types 0x00 to 0x0F. A short packet can be used for frame or line synchronization or for generic data. [Figure 6-23](#) shows the structure of a short packet.

Figure 6-23. Camera ISP CSI2 Short Packet Structure

For frame-synchronization data types, the short packet data field is the frame number. For line-synchronization data types, the short packet data field is the line number. For generic short packet data types, the content of the short packet data field is user-defined.

The 16-bit frame number, when used, is always nonzero to distinguish it from the use case where the frame number is inoperative and remains set to 0. The behavior of the 16-bit frame number is one of the following:

- The frame number is always 0. The frame number is inoperative.
- The frame number increments by 1 for every FS packet with the same virtual channel and is periodically reset to 1 (1, 2, 1, 2, 1, 2, 1, 2 or 1, 2, 3, 4, 1, 2, 3, 4).

For line-start code (LSC) and line-end code (LEC) synchronization packets, the short packet data field contains a 16-bit line number. This line number is the same for the LS and LE packets corresponding to a given line. Line numbers are logical line numbers and do not necessarily equal physical line numbers. The 16-bit line number, when used, is always nonzero to distinguish it from the case where the line number is inoperative and remains set to 0.

The behavior of the 16-bit line number is one of the following:

- The line number is always 0. The line number is inoperative.
- The line number increments by one for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to 1 for the first LS packet after an FS packet. The intended usage is for progressive scan (non-interlaced) video data streams. The line number must be a nonzero value.
- The line number increments by the same arbitrary step value greater than one for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to a nonzero arbitrary start value for the first LS packet after an FS packet. The arbitrary start value can be

different between successive frames. The intended usage is for interlaced video data streams.

The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the short packet.

Short packets apply to all contexts using the same virtual channel ID (there are up to eight contexts to support eight dedicated configurations of virtual channel ID and data types). The data type associated with the context is not used to distinguish which context is used when receiving short packets.

6.2.4.5.2.2 Camera ISP CSI2 Long Packet

A long packet is identified by data types 0x10 to 0x37. A long packet consists of three elements: a 32-bit packet header (PH), an application-specific data payload with a variable number of 8-bit data words, and a 16-bit packet footer (PF). The packet header is further composed of three elements: an 8-bit data identifier, a 16-bit word count field, and an 8-bit ECC. The packet footer has one element, a 16-bit checksum. [Figure 6-24](#) and [Table 6-9](#) show the structure of a long packet.

Figure 6-24. Camera ISP CSI2 Long Packet Structure

camisp-243

Table 6-9. Camera ISP CSI2 Long Packet Structure Description

Packet Part	Field Name	Size (Bit)	Description
Header	Data ID	8	Contains the virtual channel identifier and the data-type information
	Word count	16	Number of data words in the packet data. A word is 8 bits.
	ECC	8	ECC for data ID and WC field. Allows 1-bit error recovery and 2-bit error detection.
Data	Data	WC * 8	Application-specific payload (WC words of 8 bits)
Footer	Checksum	16	16-bit cyclic redundancy check (CRC) for packet data

There are no restrictions on packet data size, but each data format can impose additional restrictions on the length of the payload data (for example, a multiple of 4 bytes).

6.2.4.5.2.3 Camera ISP CSI2 Data Identifier

The data identifier byte contains the virtual channel identifier (VC) value and the data-type (DT) value, as shown in [Figure 6-25](#). The VC is in the 2 MSBs of the data identifier byte. The DT value is in the 6 LSBs of the data identifier byte.

[Figure 6-25](#) shows the data identifier structure.

Figure 6-25. Camera ISP CSI2 Data Identifier Structure

camisp-244

Virtual Channel

The CSI2 protocol layer transports virtual channels. Virtual channels are built up of frames. A frame can comprise embedded data and image-sensor data. Two contexts are used to send the two types of data separately. Each frame is identified by unique mandatory synchronization codes: frame start and frame end. The following synchronization codes are optional for the transmitter: line start and line end. A set of registers is associated with each context defined by the virtual channel ID and the data type. [Figure 6-26](#) shows a virtual channel.

Figure 6-26. Camera ISP CSI2 Virtual Channel

For more information on how the data formats are transmitted and how the data are stored in memory, see [Section 6.2.4.5.3, Camera ISP CSI2 Pixel Data Format](#).

6.2.4.5.2.4 Camera ISP CSI2 Synchronization Codes

Data reception from the image-sensor module uses four synchronization codes embedded in the serial bit-stream:

- FSC: Identifies the start of a new frame
- LSC: Identifies the start of a new line; received for every line
- LEC: Identifies the end of a line; received for every line
- FEC: Identifies the end of the current frame

[Table 6-11](#) summarizes the synchronization code values.

Table 6-11. Camera ISP CSI2 Synchronization Codes

Synchronization Code	Value	Comments
FSC	0x0	Mandatory
FEC	0x1	Mandatory
LSC	0x2	Optional
LEC	0x3	Optional
Reserved	0x4 to 0x7	Not used

6.2.4.5.2.5 Camera ISP CSI2 Generic Short Packet Codes

When the synchronization code value is between 0x8 and 0xF, the short packet is called a generic short packet. Short packets are not processed by the camera interface hardware. A generic short packet is stored in a register without the ECC and an interrupt can be generated. Therefore, generic short packets must be handled by software.

6.2.4.5.2.6 Camera ISP CSI2 Generic Long Packet Codes

The code value 0x10 indicates null packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x11 indicates blanking packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x12 indicates embedded 8-bit non-image data typically used for JPEG.

Code values from 0x13 to 0x17 are reserved.

6.2.4.5.2.7 Camera ISP CSI2 Frame Structure

Each frame consists of short packets to indicate start of frame and end of frame. Optional short packets for start of line and end of line can be sent by the image sensor.

Some information before and after the picture data can be sent as start-of-frame (SOF) and end-of-frame (EOF) information by the image sensor to the memory through the L3 port.

For each frame, the pixel data (arbitrary data or user-defined byte data) are valid only after an SOF short packet. If the data are invalid, they are discarded by the protocol engine.

A frame comprises embedded data and image-sensor data. [Figure 6-27](#) shows where the embedded data and image sensor data are in the frame. The following definitions apply:

- Zero or more SOF status lines (SOF lines) can be embedded at the beginning of a CSI2 frame.
- The image data comprises pixels of the same or different data formats.
- Zero or more EOF status lines (EOF lines) can be embedded at the end of a CSI2 frame.
- The SOF lines, pixel data, and EOF lines do not overlap.

The CSI2 receiver does not use the information in the status lines. However, it extracts it and stores it in memory for software use.

Because the data types are different, the CSI2 receiver uses a different context for embedded data and image-sensor data.

Embedded data is supported as a context by the CSI2 receiver; therefore, there is no specific hardware support for embedded data.

Figure 6-27. Camera ISP CSI2 General Frame Structure (Informative)

Figure 6-47. Camera ISP CSI2 JPEG8

JPEG8 (Embedded 8-bit non-image data)

Transmitter

Receiver

6.2.4.5.3.5 Camera ISP CSI2 Generic Format

The CSI2 receiver supports a generic format to send data to memory and/or the video port. The generic mode is entered by setting the [CSI2_CTX_CTRL1\[30\]](#) GENERIC bit. The [CSI2_CTX_CTRL2\[9:0\]](#) FORMAT register defines how the data stream is decoded. When generic mode is enabled (GENERIC = 1), MIPI data type code is ignored and data is decoded using the FORMAT bit. Whatever the MIPI data type code, it is ignored (the data stream is processed even if the FORMAT bit does not match the MIPI data type code). When generic mode is not used (GENERIC = 0), the data stream is processed only when the MIPI data type code matches the FORMAT setting of the enabled context. If it does not match, the data stream is not processed by the CSI2 engine. Only the virtual channel information is used to map a received data stream to a context. Software must ensure that a MIPI virtual channel used in generic mode is only mapped to a single context.

Figure 6-48. Camera ISP CSI2 Generic

ISS CSI2 Generic: [CSI2_CTX_CTRL1_i\[30\]](#) GENERIC = 0x1

Transmitter

Receiver when, for example, [CSI2_CTX_CTRL2\[9:0\]](#) FORMAT = RAW8

6.2.4.5.3.6 Camera ISP CSI2 Byte-Swap

The CSI2 receiver incorporates a byte-swap function. Software can optionally enable byte-swapping of the payload data by setting the [CSI2_CTX_CTRL1\[31\]](#) BYTESWAP bit. This feature must only be used when the amount of payload data per packet is a multiple of 16 bits. The byte-swapping is performed before pixel reconstruction.

6.3 Camera ISP Integration

[Figure 6-50](#) shows the Camera ISP integration.

Figure 6-50. Camera ISP Integration

6.3.1 Camera ISP Clocking, Reset, and Power-Management Scheme

6.3.1.1 Camera ISP Clocks

There are six clock domains in the camera ISP:

- Functional clock domain, this clock is from L3 interconnect along with Interface master write port clock. It is required to be 2x faster than the pixel clock.
- CSI1/CCP2B Serial interface clock domain. Only the parallel mode between the PHYs and the ISP is used.

- CSI2 serial interface clock domain
- CSI2 byte clock domain, whose frequency depends on the image sensor type and size, its frame rate and its blanking period. The clock is generated from the bit-clock from the sensor and converted into byte clock.
- Parallel interface clock domain. This frequency depends on the imaging sensor type and size, its frame rate and its blanking time. The functional clock is required to be at least 2x faster than the pixel clock when the bridge is disabled and a least equal when it is enabled.
- Slave interface clock domain, from L4 interconnect

6.3.1.1.1 Camera ISP Clock Tree

Figure 6-51 shows the clock tree for the camera ISP module.

Figure 6-51. Camera ISP Clock Tree Diagram

6.3.1.1.2 Camera ISP Clock Descriptions

Table 6-12 describes the camera ISP clocks.

Table 6-12. Camera ISP Clock Descriptions

Signal Name	IO	Description
CAM_FCLK	Input	Functional clock (L3 interconnect clock domain)
CAM_ICLK	Input	Interface clock (L4 interconnect clock domain)
CAM_MCLK ⁽¹⁾	Input	Internal clock from PRCM at 216 MHz. The CAM_MCLK is used by the clock generator to generate cam_xclka and cam_xclkb. It is also used by the control Signal generator to generate cam_shutter, cam_strobe, and cam_global_reset. For more information, see Section 6.4.4, Camera ISP Timing Control.
cam_xclka	Output	External clock for the image-sensor module. For serial or parallel sensor.

⁽¹⁾ The CAM_MCLK frequency can be less than, or equal to 216 MHz.

Table 6-12. Camera ISP Clock Descriptions (continued)

Signal Name	IO	Description
cam_xclk	Output	External clock for the image-sensor module. For serial or parallel sensor.
cam_pclk	Input	Parallel mode: pixel clock for parallel input data. The data on the parallel interface are presented on cam_d, one pixel for every cam_pclk rising or falling edge. Parallel sensor clock domain.
CSI2_96M_FCLK	Input	CSI2 functional clock driven by PRCM.CM_FCLKEN_CAM[1] EN_CSI2.

6.3.1.1.3 Camera ISP Clock Configuration

- CSI2_96M_FCLK is the CSI2 functional clock running at 96 MHz and enabled when PRCM.CM_FCLKEN_CAM[1] EN_CSI2 = 1
- CAM_FCLK control and settings

The CAM_FCLK clock runs at the device L3 clock frequency.

The CAM_FCLK source is the PRCM CAM_L3_ICLK output.

When the camera ISP no longer needs CAM_FCLK, the software can disable it at PRCM level by setting the PRCM.CM_ICLKEN_CAM [0] EN_CAM bit to 0x0. The clock is not effectively shut down until the camera ISP module has reached the IDLE state (that is, it does not generate anymore traffic on the device interconnect and is internally idled). For information, note that an automatic HW handshake protocol takes place between the camera ISP and the PRCM to prevent CAM_FCLK from being cut while the module is processing or transferring data.

An autoidle mode can be activated for this clock (PRCM.CM_AUTOIDLE_CAM [0] AUTO_CAM bit set to 1). This allows global management of the CAM_FCLK clock along with the CAM power domain at PRCM level. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

- CAM_ICLK control and settings:

CAM_ICLK is the interface clock. It runs at device L4 interconnect clock speed and triggers access to the camera ISP L4 interface. Its source is the PRCM CAM_L4_ICLK output.

When the camera ISP no longer needs CAM_ICLK, the software can disable it at PRCM level by setting to 0x0 the PRCM.CM_ICLKEN_CAM [0] EN_CAM bit. The clock is not effectively shut down until the camera ISP module has reached the IDLE state (that is, It does not generate anymore traffic on the device interconnect and is internally idled). As information, note an automatic HW handshake protocol takes place between the camera ISP and the PRCM to prevent CAM_ICLK from being cut while the module is processing or transferring data.

An autoidle mode can be activated for this clock (PRCM.CM_AUTOIDLE_CAM [0] AUTO_CAM bit set to 1). This allows global management of the CAM_ICLK clock along with the CAM power domain at PRCM level. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

- CAM_MCLK control and settings:

The source for CAM_MCLK is the PRCM CAM_MCLK output. It is generated through a peripheral DPLL and its frequency can be adjusted using the PRCM.CM_CLKSEL_CAM[4:0] CLKSEL_CAM bit field.

When the module no longer needs it, it can be disabled at PRCM level by setting the PRCM.CM_FCLKEN_CAM[0] EN_CAM bit to 0x0. The PRCM register bit setting has a direct effect on the clock; in other terms, there is no HW handshake protocol to ensure whether the clock can be cut regarding the camera ISP activity: as soon as the bit is set to 0x0, CAM_MCLK is shut down.

- cam_xclka and cam_xclk control and settings:

cam_xclka and cam_xclk are generated inside the camera ISP module from CAM_MCLK clock input. [Table 6-13](#) and [Table 6-14](#) give the settings of the related bit fields.

Table 6-13. Camera ISP cam_xclka Configuration

ref_clk	CAM.TCTRL_CTRL[4:0] DIVA field	cam_xclka
CAM_MCLK	0x0	Stable low level. Divider disabled.
	0x1	Stable high level. Divider disabled.

	0x2	CAM_MCLK/2

	0x1F	CAM_MCLK

Table 6-14. Camera ISP cam_xclkb Configuration

ref_clk	CAM.TCTRL_CTRL[9:5] DIVB field	cam_xclkb
CAM_MCLK	0x0	Stable low level. Divider disabled.
	0x1	Stable high level. Divider disabled.
	0x2	CAM_MCLK/2

	0x1F	CAM_MCLK

6.3.1.2 Camera ISP Power Management

Power consumption can be reduced at two different levels:

- A local power-management optimization
- A system power management

6.3.1.2.1 Camera ISP Local Power Management

To optimize power consumption, a local autoidle feature is implemented on the CAM_ICLK interface clock at camera ISP module level. By enabling this autoidle feature, CAM_ICLK is automatically gated at the module boundary as soon as it is not required and restarted without any latency when needed again. This allows power saving when the module is not involved in any transfer from/to the device interconnect. This autoidle feature is enabled by setting:

- **ISP_SYSCONFIG** [0] AUTO_IDLE bit to 1
- **CCP2_SYSCONFIG** [0] AUTO_IDLE bit to 1
- **CSI2_SYSCONFIG** [0] AUTO_IDLE bit to 1
- **MMU.MMU_SYSCONFIG** [0] AUTOIDLE bit to 1
- **ISP_CTRL** [21] SBL_AUTOIDLE bit to 1

The decision to gate the interconnect clock is based on interface activity, regardless of hardware handshake protocols.

After a reset, this mode is enabled, by default.

NOTE: It is recommended that this mode be enabled to reduce power consumption.

6.3.1.2.2 Camera ISP System Power Management

As part of the system power management scheme, the camera ISP module interacts with the PRCM through an automatic standby hardware protocol that allows dynamic power savings at CAMERA power domain level.

Being an initiator on the L3 interconnect, the camera ISP module alerts the PRCM as soon as it is ready to switch to a lower power state. Prior to any power state change to the CAMERA power domain, the PRCM first shuts off the camera clocks, depending on the camera ISP behavior and the clock settings at PRCM level. Namely, as soon as the camera ISP is ready to go to STANDBY, it asserts an automatic HW STANDBY request to the PRCM, which shuts down the clocks if they have been previously disabled by software and then potentially change the CAMERA power domain state. Refer to [Chapter 3, Power, Reset, and Clock Management](#), for further details.

When it goes to standby, the camera ISP module alerts the PRCM differently, depending on the [ISP_SYSConfig \[13:12\] MIDLE_MODE](#) bit field settings. The entry conditions for the camera ISP to go into standby mode are:

- The module has finished any current transaction and does not generate any more traffic on the interconnect.
- The module is idle (on-going transactions are finished).

The MIDLE_MODE bit field allows the following settings for the camera ISP module:

- Force standby

The camera ISP is set to force standby when MIDLE_MODE is set to 0x0. In this mode, the camera ISP module asserts its HW standby request to the PRCM as soon as it is disabled. Namely, the camera ISP is disabled when the following bit fields are set to 0x0:

- [ISP_CTRL \[13\] RSZ_CLK_EN](#)
- [ISP_CTRL \[12\] PRV_CLK_EN](#)
- [ISP_CTRL \[11\] HIST_CLK_EN](#)
- [ISP_CTRL \[10\] H3A_CLK_EN](#)
- [ISP_CTRL \[8\] CCDC_CLK_EN](#)

Moreover, CSI2A and CSI2C receivers must also be disabled by setting the related [CSI2_CTRL\[0\] IF_EN](#) bits to 0x0 and CSI1/CCP2B must also be disabled by setting the related [CCP2_CTRL \[0\] IF_EN](#) bits to 0x0.

- No standby

The camera ISP is set to no standby when MIDLE_MODE is set to 0x1. In this mode, the camera ISP module never asserts its standby request to the PRCM. This also prevents the CAMERA power domain from going to a lower power state. Refer to [Chapter 3, Power, Reset, and Clock Management](#), for further details.

- Smart standby

The camera ISP module is set to smart standby when MIDLE_MODE is set to 0x2. In this mode, the camera ISP module asserts its HW standby request to the PRCM according with its internal activity (namely, when there is no more activity on the camera ISP master interface, that is, when there is no more data in the central resource buffer).

NOTE: The CSI1/CCP2B receiver must also be configured to smart standby mode when the camera ISP is set to smart standby ([CCP2_SYSConfig \[13:12\] MSTANDBY_MODE](#) set to 0x2).

CSI2A and CSI2C receivers must also be configured to smart standby mode when the camera ISP is set to smart standby ([CSI2_SYSConfig\[13:12\] MSTANDBY_MODE](#) set to 0x2).

A standby request asserted to the PRCM does not necessarily lead to CAM_FCLK and CAM_ICLK being cut. The PRCM must also be set correctly for that purpose.

The clocks are cut, allowing a CAMERA power state change if:

- PRCM.CM_ICLKEN_CAM[0] EN_CAM = 0 and PRCM.CM_FCLKEN_CAM[0] EN_CAM = 0
- PRCM.CM_FCLKEN_CAM[0] EN_CAM = 0, (PRCM.CM_ICLKEN_CAM[0] EN_CAM =1, PRCM.CM_AUTOIDLE_CAM[0] = 1, and a domain transition is required at PRCM level)

See [Chapter 3, Power, Reset, and Clock Management](#), for further details.

6.3.1.3 Camera ISP Power Domain

The camera ISP belongs to the CAMERA power domain. For more information about the CAMERA power domain, see [Chapter 3, Power, Reset, and Clock Management](#).

6.3.1.4 Camera ISP Resets

6.3.1.4.1 Camera ISP Hardware Reset

Global reset of the camera ISP module is accomplished by activation of the CAM_RST signal in the CAMERA domain (for more information, see [Chapter 3, Power, Reset, and Clock Management](#)).

6.3.1.4.2 Camera ISP Software Reset

A global software reset can be accomplished by setting the camera ISP [ISP_SYSCONFIG \[1\]](#) SOFT_RESET bit to 1. Setting this bit enables active software reset functionality equivalent to hardware reset for the entire module, including CSI1/CCP2B,CSI2A, and CSI2C receivers.

NOTE: The CSI1/CCP2B receiver accepts a general software reset, propagated through the hierarchy. This reset can be performed to initialize the module and has the same effect as a hardware reset.

The CSI1/CCP2B receiver can be reset by writing [CCP2_SYSCONFIG \[1\]](#) SOFT_RESET bit to 1. The software can monitor the [CCP2_SYSSTATUS \[0\]](#) RESET_DONE status bit to wait for the completion of the reset procedure.

If after five reads, [CCP2_SYSSTATUS \[0\]](#) RESET_DONE still returns 0, it can be assumed that an error occurred during the reset stage.

The CSI2A and CSI2C receivers accept a general software reset, propagated through the hierarchy. This reset can be performed to initialize the module and has the same effect as a hardware reset.

The CSI2A and CSI2C receivers can be reset by writing [CSI2_SYSCONFIG \[1\]](#) SOFT_RESET bit to 1. The software can monitor the [CSI2_SYSSTATUS \[0\]](#) RESET_DONE status bit to wait for the completion of the reset procedure.

If after five reads, [CSI2_SYSSTATUS \[0\]](#) RESET_DONE still returns 0, it can be assumed that an error occurred during the reset stage.

6.3.2 Camera ISP Hardware Requests

6.3.2.1 Camera ISP Interrupt Requests

[Figure 6-52](#) shows the interrupt generation tree of the camera subsystem.

Figure 6-52. Camera ISP Interrupt Generation Tree

camisp-231

 (1) $x = 0 \text{ to } 7$

The camera ISP can generate two interrupts:

- CAM_IRQ0 is an interrupt to the MPU subsystem interrupt controller. It is mapped on M_IRQ_24.
- CAM_IRQ1 is an interrupt to the IVA2.2 subsystem interrupt controller. It is mapped on IVA2_IRQ[11].

[Table 6-15](#) summarizes events that cause interrupts.

Table 6-15. Camera ISP Interrupts

Event	Mask	Description
ISP_IRQ0STATUS [31] HS_VS_IRQ	ISP_IRQ0ENABLE [31] HS_VS_IRQ	HS or VS synchronization event: triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection are chosen with the ISP_CTRL [15:14] SYNC_DETECT bit field. ⁽¹⁾
ISP_IRQ0STATUS [28] MMU_ERR_IRQ	ISP_IRQ0ENABLE [28] MMU_ERR_IRQ	MMU error

⁽¹⁾ This event is detected on the incoming HS/VS signals before the CCDC. Therefore, it cannot be used in BT656 mode.

Table 6-15. Camera ISP Interrupts (continued)

Event	Mask	Description
ISP_IRQ0STATUS [25] OVF_IRQ	ISP_IRQ0ENABLE [25] OVF_IRQ	Central-resource SBL overflow: triggered when one of the buffers in the central-resource SBL overflows
ISP_IRQ0STATUS [24] RSZ_DONE_IRQ	ISP_IRQ0ENABLE [24] RSZ_DONE_IRQ	RESIZER module. Resizer processing-done event: Triggered at the end of the frame when processing is complete for the current frame. It applies to one-shot and continuous modes.
ISP_IRQ0STATUS [21] CBUFF_IRQ	ISP_IRQ0ENABLE [24] CBUFF_IRQ	CBUFF module event. See CBUFF_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [20] PRV_DONE_IRQ	ISP_IRQ0ENABLE [20] PRV_DONE_IRQ	PREVIEW module: Processing-done event: triggered at the end of the frame when processing is complete for the current frame
ISP_IRQ0STATUS [19] CCDC_LSC_PREFETCH_ERROR	ISP_IRQ0ENABLE [19] PRV_DONE_IRQ	CCDC module. The prefetch error indicates when the gain table was read too slowly from memory. When this event is pending, the module goes into transparent mode (output = input). Normal operation can be resumed at the start of the next frame after: 1) Clearing this event 2) Disabling the LSC module 3) Enabling it
ISP_IRQ0STATUS [18] CCDC_LSC_PREFETCH_COMPLETE_D	ISP_IRQ0ENABLE [18] CCDC_LSC_PREFETCH_COMPLETED	CCDC module. Indicates the current state of the prefetch buffer. Can be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full pixel rows. It can be used to minimize buffer underflow risks.
ISP_IRQ0STATUS [17] CCDC_LSC_DONE	ISP_IRQ0ENABLE [17] CCDC_LSC_DONE	CCDC module. The event is triggered when the internal state of LSC toggles from BUSY to IDLE. This happens when the LSC module has completed processing the current frame.
ISP_IRQ0STATUS [16] HIST_DONE_IRQ	ISP_IRQ0ENABLE [16] HIST_DONE_IRQ	HIST module. Processing-done event: triggered at the end of the frame when processing is complete for the current frame
ISP_IRQ0STATUS [13] H3A_AWB_DONE_IRQ	ISP_IRQ0ENABLE [13] H3A_AWB_DONE_IRQ	H3A module. Auto exposure and auto white balance processing done event: Triggered at the end of the frame when processing is complete for the current frame
ISP_IRQ0STATUS [12] H3A_AF_DONE_IRQ	ISP_IRQ0ENABLE [12] H3A_AF_DONE_IRQ	H3A module. Autofocus processing-done event: triggered at the end of the frame when processing is complete for the current frame
ISP_IRQ0STATUS [11] CCDC_ERR_IRQ	ISP_IRQ0ENABLE [11] CCDC_ERR_IRQ	CCDC module. Faulty-pixel correction error: Faulty-pixel correction memory underflow. Triggered to signal an error in the faulty-pixel correction logic. The hardware did not have time to read the faulty-pixel LUT from external memory in time.
ISP_IRQ0STATUS [10] CCDC_VD2_IRQ	ISP_IRQ0ENABLE [10] CCDC_VD2_IRQ	CCDC module. Programmable event 2: triggered by the falling edge on the cam_wen signal. This event is not programmable.
ISP_IRQ0STATUS [9] CCDC_VD1_IRQ	ISP_IRQ0ENABLE [9] CCDC_VD1_IRQ	CCDC module. Programmable event 1: triggered after a programmable number of horizontal lines is received after a VS pulse
ISP_IRQ0STATUS [8] CCDC_VD0_IRQ	ISP_IRQ0ENABLE [8] CCDC_VD0_IRQ	CCDC module. Programmable event 0: triggered after a programmable number of horizontal lines is received after a VS pulse
ISP_IRQ0STATUS [7] CSI1_LC3_IRQ	ISP_IRQ0ENABLE [4] CSI1_LC3_IRQ	CSI1/CCP2B receiver module event. See CCP2_LC23_IRQSTATUS to know which interrupt it is.

Table 6-15. Camera ISP Interrupts (continued)

Event	Mask	Description
ISP_IRQ0STATUS [6] CSI1_LC2_IRQ	ISP_IRQ0ENABLE [4] CSI1_LC2_IRQ	CSI1/CCP2B receiver module event. See CCP2_LC23_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [5] CSI1_LC1_IRQ	ISP_IRQ0ENABLE [4] CSI1_LC1_IRQ	CSI1/CCP2B receiver module event. See CCP2_LC01_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [4] CSI1_LC0_IRQ	ISP_IRQ0ENABLE [4] CSI1_LC0_IRQ	CSI1/CCP2B receiver module event. See CCP2_LC01_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [3] CSI1_LCM_IRQ	ISP_IRQ0ENABLE [3] CSI1_LCM_IRQ	CSI1 receiver module event on memory channel.
ISP_IRQ0STATUS [1] CSI2C_IRQ	ISP_IRQ0ENABLE [1] CSI2C_IRQ	CSI2C receiver module event. See CSI2_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [0] CSI2A_IRQ	ISP_IRQ0ENABLE [0] CSI2A_IRQ	CSI2A receiver module event. See CSI2_IRQSTATUS to know which interrupt it is.

NOTE: n is equal to 0 or 1.

I is equal to 01 or 23.

Table 6-16 summarizes the CBUFF interrupts.

Table 6-16. Camera ISP CBUFF Interrupt Details

Event	Mask	Description
CBUFF_IRQSTATUS [5] IRQ_CBUFF1_OVR	CBUFF_IRQENABLE [5] IRQ_CBUFF1_OVR	Buffer overflow event: The generation of this event depends on the CBUFFx_CTRL.ALLOW_NW_EQ_CR flag and the circular buffer mode (read or write). This event indicates a bandwidth mismatch between data producer and data consumer. When it occurs, CBUFFx does NOT go into error state. However, the data in the physical buffer is very likely to be corrupted.
CBUFF_IRQSTATUS [4] IRQ_CBUFF1_INVALID	CBUFF_IRQENABLE [4] IRQ_CBUFF1_INVALID	<p>Invalid access:</p> <ul style="list-style-type: none"> • Camera controller writes the virtual space of CBUFFx in read mode. • Camera controller reads the virtual space of CBUFFx in write mode. • HW writes the virtual space of circular buffer x outside the CW or NW window in write mode. • HW reads the virtual space of circular buffer x outside the CW or NW window in read mode. • NW full • CPU write the DONE bit when physical buffers are not ready for the CPU. <p>This event indicates a wrong configuration of the circular buffer, the camera ISP, or bogus software. When it occurs, CBUFFx goes into an error state. In this state all accesses to the virtual space of CBUFFx are cancelled: they are not forwarded to the physical space. The purpose is to prevent corruption of the physical memory.</p> <p>The error state can be left by disabling the CBUFFx and reenabling it. Before doing so, the SW must ensure that there are no more outstanding requests to the virtual space of CBUFFx.</p>

Table 6-16. Camera ISP CBUFF Interrupt Details (continued)

Event	Mask	Description
CBUFF IRQSTATUS [3] IRQ_CBUFF1_READY	CBUFF IRQENABLE [3] IRQ_CBUFF1_READY	The CPUW1 physical buffer is ready to be accessed by the CPU.
CBUFF IRQSTATUS [2] IRQ_CBUFF0_OVR	CBUFF IRQENABLE [2] IRQ_CBUFF0_OVR	Buffer overflow event. See description of IRQ_CBUFF1_OVR event.
CBUFF IRQSTATUS [1] IRQ_CBUFF0_INVALID	CBUFF IRQENABLE [1] IRQ_CBUFF0_INVALID	Invalid access. See description of IRQ_CBUFF1_INVALID event.
CBUFF IRQSTATUS [0] IRQ_CBUFF0_READY	CBUFF IRQENABLE [0] IRQ_CBUFF0_READY	The CPUW1 physical buffer is ready to be accessed by the CPU

Table 6-17 describes the CSI1/CCP2B receiver interrupts.

Table 6-17. Camera ISP CSI1/CCP2B Receiver Interrupt Details

Event	Mask	Description
CCP2_LC01_IRQSTATUS[27] LC1_FS_IRQ	CCP2_LC01_IRQENABLE[27] LC1_FS_IRQ	Frame-start synchronization code detection for logical channel 1: This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[26] LC1_LE_IRQ	CCP2_LC01_IRQENABLE[26] LC1_LE_IRQ	Line-end synchronization code detection for logical channel 1: This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[25] LC1_LS_IRQ	CCP2_LC01_IRQENABLE[25] LC1_LS_IRQ	Line-start synchronization code detection for logical channel 1: This interrupt is triggered on the detection of a line-start synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[24] LC1_FE_IRQ	CCP2_LC01_IRQENABLE[24] LC1_FE_IRQ	Frame-end synchronization code detection for logical channel 1: This interrupt is triggered on the detection of a frame-end synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[23] LC1_COUNT_IRQ	CCP2_LC01_IRQENABLE[23] LC1_COUNT_IRQ	Frame counter reached for logical channel 1: This interrupt is triggered when the frame counter has reached its programmable target value.
CCP2_LC01_IRQSTATUS[21] LC1_FIFO_OVF_IRQ	CCP2_LC01_IRQENABLE[21] LC1_FIFO_OVF_IRQ	FIFO overflow error for logical channel 1: This interrupt is triggered upon detection of a FIFO overflow. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC01_IRQSTATUS[20] LC1_CRC_IRQ	CCP2_LC01_IRQENABLE[20] LC1_CRC_IRQ	CRC error for logical channel 1: This interrupt is triggered upon detection of a mismatch between the transmitter and receiver checksums. This interrupt does not apply to the MIPI CSI1 compatible mode.
CCP2_LC01_IRQSTATUS[19] LC1_FSP_IRQ	CCP2_LC01_IRQENABLE[19] LC1_FSP_IRQ	False synchronization code protection error for logical channel 1: This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bit stream.
CCP2_LC01_IRQSTATUS[18] LC1_FW_IRQ	CCP2_LC01_IRQENABLE[18] LC1_FW_IRQ	Frame-width error for logical channel 1: This interrupt is generated if the frame width constraints associated to the current data type is not respected.
CCP2_LC01_IRQSTATUS[17] LC1_FSC_IRQ	CCP2_LC01_IRQENABLE[17] LC1_FSC_IRQ	False synchronization code error for logical channel 1: This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver finite state-machine.

Table 6-17. Camera ISP CSI1/CCP2B Receiver Interrupt Details (continued)

Event	Mask	Description
CCP2_LC01_IRQSTATUS[16] LC1_SSC IRQ	CCP2_LC01_IRQENABLE[16]LC1_SSC IRQ	Shifted synchronization code error for logical channel 1: This interrupt is triggered if LEC or FEC are not aligned on a 32-bit boundary. This state is shown in the CCP2 receiver finite state-machine. The shifted synchronization code error is highlighted in the CCP2 receiver finite state-machine. ⁽¹⁾
CCP2_LC01_IRQSTATUS[11] LC0_FS IRQ	CCP2_LC01_IRQENABLE[11] LC0_FS IRQ	Frame-start synchronization code detection for logical channel 0: This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[10] LC0_LE IRQ	CCP2_LC01_IRQENABLE[10] LC0_LE IRQ	Line-end synchronization code detection for logical channel 0: This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[9] LC0_LS IRQ	CCP2_LC01_IRQENABLE[9] LC0_LS IRQ	Line-start synchronization code detection for logical channel 0: This interrupt is triggered on the detection of a line-start synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[8] LC0_FE IRQ	CCP2_LC01_IRQENABLE[8] LC0_FE IRQ	Frame-end synchronization code detection for logical channel 0: This interrupt is triggered on the detection of a frame-end synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[7] LC0_COUNT IRQ	CCP2_LC01_IRQENABLE[7] LC0_COUNT IRQ	Frame counter reached for logical channel 0: This interrupt is triggered on the frame counter reached into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[5] LC0_FIFO_OVF IRQ	CCP2_LC01_IRQENABLE[5] LC0_FIFO_OVF IRQ	FIFO overflow error for logical channel 0: This interrupt is triggered on the detection of a FIFO overflow error.
CCP2_LC01_IRQSTATUS[4] LC0_CRC IRQ	CCP2_LC01_IRQENABLE[4] LC0_CRC IRQ	CRC error This interrupt is triggered on the detection of a CRC error into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[3] LC0_FSP IRQ	CCP2_LC01_IRQENABLE[3] LC0_FSP IRQ	False synchronization code protection error for logical channel 0: This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bit stream.
CCP2_LC01_IRQSTATUS[2] LC0_FW IRQ	CCP2_LC01_IRQENABLE[2] LC0_FW IRQ	Frame-width error for logical channel 0: This interrupt is triggered on the detection of a frame-width error into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[1] LC0_FSC IRQ	CCP2_LC01_IRQENABLE[1] LC0_FSC IRQ	False synchronization code error for logical channel 0: This interrupt is triggered on the detection of a false synchronization code error into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[0] LC0_SSC IRQ	CCP2_LC01_IRQENABLE[0] LC0_SSC IRQ	Shifted synchronization code error for logical channel 0: This interrupt is triggered if LEC or FEC are not aligned on a 32-bit boundary. This state is shown in the CCP2 receiver finite state-machine. The shifted synchronization code error is highlighted in the CCP2 receiver finite state-machine. ⁽²⁾
CCP2_LC23_IRQSTATUS[27] LC3_FS IRQ	CCP2_LC23_IRQENABLE[27] LC3_FS IRQ	Frame-start synchronization code detection for logical channel 3: This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream

⁽¹⁾ This error can be triggered if the complex I/O cell is used in parallel output mode (CCP_CTRL[2]IO_OUT_SEL=1).

⁽²⁾ This error can be triggered if the complex I/O cell is used in parallel output mode (CCP_CTRL[2]IO_OUT_SEL=1).

Table 6-17. Camera ISP CSI1/CCP2B Receiver Interrupt Details (continued)

Event	Mask	Description
CCP2_LC23_IRQSTATUS[26] LC3_LE_IRQ	CCP2_LC23_IRQENABLE[26] LC3_LE_IRQ	Line-end synchronization code detection for logical channel 3: This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[25] LC3_LS_IRQ	CCP2_LC23_IRQENABLE[25] LC3_LS_IRQ	Line-start synchronization code detection for logical channel 3: This interrupt is triggered on the detection of a line-start synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[24] LC3_FE_IRQ	CCP2_LC23_IRQENABLE[24] LC3_FE_IRQ	Frame-end synchronization code detection for logical channel 3: This interrupt is triggered on the detection of a frame-end synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[23] LC3_COUNT_IRQ	CCP2_LC23_IRQENABLE[23] LC3_COUNT_IRQ	Frame counter reached for logical channel 3: This interrupt is triggered when the frame counter has reached its programmable target value.
CCP2_LC23_IRQSTATUS[21] LC3_FIFO_OVF_IRQ	CCP2_LC23_IRQENABLE[21] LC3_FIFO_OVF_IRQ	FIFO overflow error for logical channel 3: This interrupt is triggered upon detection of a FIFO overflow. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC23_IRQSTATUS[20] LC3_CRC_IRQ	CCP2_LC23_IRQENABLE[20] LC3_CRC_IRQ	CRC error for logical channel 3: This interrupt is triggered upon detection of a mismatch between the transmitter and receiver checksums. This interrupt does not apply to the MIPI CSI1 compatible mode.
CCP2_LC23_IRQSTATUS[19] LC3_FSP_IRQ	CCP2_LC23_IRQENABLE[19] LC3_FSP_IRQ	False synchronization code protection error for logical channel 3: This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bit stream.
CCP2_LC23_IRQSTATUS[18] LC3_FW_IRQ	CCP2_LC23_IRQENABLE[18] LC3_FW_IRQ	Frame-width error for logical channel 3: This interrupt is generated if the frame width constraints associated to the current data type is not respected.
CCP2_LC23_IRQSTATUS[17] LC3_FSC_IRQ	CCP2_LC23_IRQENABLE[17] LC3_FSC_IRQ	False synchronization code error for logical channel 3: This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver finite state machine.
CCP2_LC23_IRQSTATUS[16] LC3_SSC_IRQ	CCP2_LC23_IRQENABLE[16] LC3_SSC_IRQ	Shifted synchronization code error for logical channel 3: This interrupt is triggered if LEC or FEC are not aligned on a 32-bit boundary. This state is shown in the CCP2 receiver finite state-machine. The shifted synchronization code error is highlighted in the CCP2 receiver finite state-machine. ⁽³⁾
CCP2_LC23_IRQSTATUS[11] LC2_FS_IRQ	CCP2_LC23_IRQENABLE[11] LC2_FS_IRQ	Frame-start synchronization code detection for logical channel 2: This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[10] LC2_LE_IRQ	CCP2_LC23_IRQENABLE[10] LC2_LE_IRQ	Line-end synchronization code detection for logical channel 2: This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.

⁽³⁾ This error can be triggered if the complex I/O cell is used in parallel output mode (CCP_CTRL[2]IO_OUT_SEL=1).

Table 6-17. Camera ISP CSI1/CCP2B Receiver Interrupt Details (continued)

Event	Mask	Description
CCP2_LC23_IRQSTATUS[9] LC2_LS_IRQ	CCP2_LC23_IRQENABLE[9] LC2_LS_IRQ	Line-start synchronization code detection for logical channel 2: This interrupt is triggered on the detection of a line-start synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[8] LC2_FE_IRQ	CCP2_LC23_IRQENABLE[8] LC2_FE_IRQ	Frame-end synchronization code detection for logical channel 2: This interrupt is triggered on the detection of a frame-end synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[7] LC2_COUNT_IRQ	CCP2_LC23_IRQENABLE[7] LC2_COUNT_IRQ	Frame counter reached for logical channel 2: This interrupt is triggered on the frame counter reached into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[5] LC2_FIFO_OVF_IRQ	CCP2_LC23_IRQENABLE[5] LC2_FIFO_OVF_IRQ	FIFO overflow error for logical channel 2: This interrupt is triggered on the detection of a FIFO overflow error.
CCP2_LC23_IRQSTATUS[4] LC2_CRC_IRQ	CCP2_LC23_IRQENABLE[4] LC2_CRC_IRQ	CRC error for logical channel 2: This interrupt is triggered on the detection of a CRC error into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[3] LC2_FSP_IRQ	CCP2_LC23_IRQENABLE[3] LC2_FSP_IRQ	False synchronization code protection error for logical channel 2: This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bit stream.
CCP2_LC23_IRQSTATUS[2] LC2_FW_IRQ	CCP2_LC23_IRQENABLE[2] LC2_FW_IRQ	Frame-width error for logical channel 2: This interrupt is triggered on the detection of a frame-width error into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[1] LC2_FSC_IRQ	CCP2_LC23_IRQENABLE[1] LC2_FSC_IRQ	False synchronization code error for logical channel 2: This interrupt is triggered on the detection of a false synchronization code error into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[0] LC2_SSC_IRQ	CCP2_LC23_IRQENABLE[0] LC2_SSC_IRQ	Shifted synchronization code error for logical channel 2: This interrupt is triggered if LEC or FEC are not aligned on a 32-bit boundary. This state is shown in the CCP2 receiver finite state-machine. The shifted synchronization code error is highlighted in the CCP2 receiver finite state-machine. ⁽⁴⁾
CCP2_LCM_IRQSTATUS[1] LCM_OCPERROR	CCP2_LCM_IRQENABLE[1] LCM_OCPERROR	An OCP error occurred on the master read port. This interrupt is triggered on the detection of an OCP error on the master read port.
CCP2_LCM_IRQSTATUS[0] LCM_EOF	CCP2_LCM_IRQENABLE[0] LCM_EOF	Memory read channel end of frame: This interrupt is triggered when a frame has been completely read from memory.

⁽⁴⁾ This error can be triggered if the complex I/O cell is used in parallel output mode (CCP_CTRL[2]IO_OUT_SEL=1).

Table 6-18 shows CSI2A and CSI2C receivers event generation through the CSI2 interrupt status and interrupt enable registers.

Table 6-18. Camera ISP CSI2A and CSI2C Receivers Event Generation

Event	Mask	Description
CSI2_IRQSTATUS[0] CONTEXT0	CSI2_IRQENABLE[0] CONTEXT0	At least one interrupt event enabled from Context 0 occurred (see Table 6-20).
CSI2_IRQSTATUS[1] CONTEXT1	CSI2_IRQENABLE[1] CONTEXT1	At least one interrupt event enabled from Context 1 occurred (see Table 6-20).
CSI2_IRQSTATUS[2] CONTEXT2	CSI2_IRQENABLE[2] CONTEXT2	At least one interrupt event enabled from Context 1 occurred (see Table 6-20).
CSI2_IRQSTATUS[3] CONTEXT3	CSI2_IRQENABLE[3] CONTEXT3	At least one interrupt event enabled from Context 3 occurred (see Table 6-20).

Table 6-18. Camera ISP CSI2A and CSI2C Receivers Event Generation (continued)

Event	Mask	Description
<code>CSI2_IRQSTATUS[4] CONTEXT4</code>	<code>CSI2_IRQENABLE[4] CONTEXT4</code>	At least one interrupt event enabled from Context 4 occurred (see Table 6-20).
<code>CSI2_IRQSTATUS[5] CONTEXT5</code>	<code>CSI2_IRQENABLE[5] CONTEXT5</code>	At least one interrupt event enabled from Context 5 occurred (see Table 6-20).
<code>CSI2_IRQSTATUS[6] CONTEXT6</code>	<code>CSI2_IRQENABLE[6] CONTEXT6</code>	At least one interrupt event enabled from Context 6 occurred (see Table 6-20).
<code>CSI2_IRQSTATUS[7] CONTEXT6</code>	<code>CSI2_IRQENABLE[7] CONTEXT7</code>	At least one interrupt event enabled from Context 7 occurred (see Table 6-20).
<code>CSI2_IRQSTATUS[8] FIFO_OVF_IRQ</code>	<code>CSI2_IRQENABLE[8] FIFO_OVF_IRQ</code>	FIFO overflow error: This interrupt is triggered on detection of a FIFO overflow. An overflow can occur if there is a mismatch between the data input and output rates. A reset of the module is required to restart correctly.
<code>CSI2_IRQSTATUS[9] PHY_ERR_IRQ</code>	<code>CSI2_IRQENABLE[9] PHT_ERR_IRQ</code>	Error signaling from PHY: This interrupt is triggered when any error is received from the PHY (events are defined in <code>CSI2_COMPLEXIO1_IRQSTATUS</code> [see Table 6-19]).
<code>CSI2_IRQSTATUS[11] ECC_NO_CORRECTION_IRQ</code>	<code>CSI2_IRQENABLE[11] ECC_NO_CORRECTION_IRQ</code>	ECC was not used to correct the header because the error is larger than 1 bit (short and long packets).
<code>CSI2_IRQSTATUS[12] ECC_CORRECTION_IRQ</code>	<code>CSI2_IRQENABLE[12] ECC_CORRECTION_IRQ</code>	ECC was used to correct a 1-bit error (short packet only).
<code>CSI2_IRQSTATUS[13] SHORT_PACKET_IRQ</code>	<code>CSI2_IRQENABLE[13] SHORT_PACKET_IRQ</code>	Short packet reception (other than sync events: line start, line end, frame start, and frame end; only data types between 0x8 and 0xF are considered).
<code>CSI2_IRQSTATUS[14] OCP_ERR_IRQ</code>	<code>CSI2_IRQENABLE[14] OCP_ERR_IRQ</code>	OCP error

[Table 6-19](#) shows CSI2A and CSI2C receiver event generation interrupt status and interrupt enable registers receiving signals from the associated PHY.

Table 6-19. Camera ISP CSI2A and CSI2C Receiver Event Generation from PHY

Event	Mask	Description
<code>CSI2_COMPLEXIO1_IRQSTATUS[0] ERRSOTHS1</code>	<code>CSI2_COMPLEXIO1_IRQENABLE[0] ERRSOTHS1</code>	Start of transmission error for lane 1
<code>CSI2_COMPLEXIO1_IRQSTATUS[1] ERRSOTHS2</code>	<code>CSI2_COMPLEXIO1_IRQENABLE[1] ERRSOTHS2</code>	Start of transmission error for lane 2
<code>CSI2_COMPLEXIO1_IRQSTATUS[2] ERRSOTHS3</code>	<code>CSI2_COMPLEXIO1_IRQENABLE[2] ERRSOTHS3</code>	Start of transmission error for lane 3
<code>CSI2_COMPLEXIO1_IRQSTATUS[5] ERRSOTSYNCHS1</code>	<code>CSI2_COMPLEXIO1_IRQENABLE[5] ERRSOTSYNCHS1</code>	Start of transmission sync error for lane 1
<code>CSI2_COMPLEXIO1_IRQSTATUS[6] ERRSOTSYNCHS2</code>	<code>CSI2_COMPLEXIO1_IRQENABLE[6] ERRSOTSYNCHS2</code>	Start of transmission sync error for lane 2
<code>CSI2_COMPLEXIO1_IRQSTATUS[7] ERRSOTSYNCHS3</code>	<code>CSI2_COMPLEXIO1_IRQENABLE[7] ERRSOTSYNCHS3</code>	Start of transmission sync error for lane 3
<code>CSI2_COMPLEXIO1_IRQSTATUS[10] ERRESC1</code>	<code>CSI2_COMPLEXIO1_IRQENABLE[10] ERRESC1</code>	Escape entry error for lane 1
<code>CSI2_COMPLEXIO1_IRQSTATUS[11] ERRESC2</code>	<code>CSI2_COMPLEXIO1_IRQENABLE[11] ERRESC2</code>	Escape entry error for lane 2
<code>CSI2_COMPLEXIO1_IRQSTATUS[12] ERRESC3</code>	<code>CSI2_COMPLEXIO1_IRQENABLE[12] ERRESC3</code>	Escape entry error for lane 3
<code>CSI2_COMPLEXIO1_IRQSTATUS[15] ERRCONTROL1</code>	<code>CSI2_COMPLEXIO1_IRQENABLE[15] ERRCONTROL1</code>	Control error for lane 1
<code>CSI2_COMPLEXIO1_IRQSTATUS[16] ERRCONTROL2</code>	<code>CSI2_COMPLEXIO1_IRQENABLE[16] ERRCONTROL2</code>	Control error for lane 2

Table 6-19. Camera ISP CSI2A and CSI2C Receiver Event Generation from PHY (continued)

Event	Mask	Description
CSI2_COMPLEXIO1_IRQSTATUS[17] ERRCONTROL3	CSI2_COMPLEXIO1_IRQENABLE[17] ERRCONTROL3	Control error for lane 3
CSI2_COMPLEXIO1_IRQSTATUS[20] STATEULPM1	CSI2_COMPLEXIO1_IRQENABLE[20] STATEULPM1	Lane 1 in ULPM
CSI2_COMPLEXIO1_IRQSTATUS[21] STATEULPM2	CSI2_COMPLEXIO1_IRQENABLE[21] STATEULPM2	Lane 2 in ULPM
CSI2_COMPLEXIO1_IRQSTATUS[22] STATEULPM3	CSI2_COMPLEXIO1_IRQENABLE[22] STATEULPM3	Lane 3 in ULPM
CSI2_COMPLEXIO1_IRQSTATUS[25] STATEALLULPMENTER	CSI2_COMPLEXIO1_IRQENABLE[25] STATEALLULPMENTER	All active lanes are entering in ULPM.
CSI2_COMPLEXIO1_IRQSTATUS[26] STATEALLULPMEXIT	CSI2_COMPLEXIO1_IRQENABLE[26] STATEALLULPMEXIT	At least one active lane exited the ULPM.

As the CSI2A and CSI2C receivers supports eight contexts, the [**CSI2_CTX_IRQSTATUS**](#) and [**CSI2_CTX_IRQENABLE**](#) registers are present eight times (one time per context).

The events are generated only for the enabled context(s). **Table 6-20** describes the CSI2A and CSI2C receiver event generation through the CTx interrupt status and interrupt enable registers.

Table 6-20. Camera ISP CSI2A and CSI2C CTx Receiver Event Generation

Event	Mask	Description
CSI2_CTX_IRQSTATUS[0] FS_IRQ	CSI2_CTX_IRQENABLE[0] FS_IRQ	Frame start: This interrupt is triggered on the detection of a frame-start synchronization code into the CSI2 data stream.
CSI2_CTX_IRQSTATUS[1] FE_IRQ	CSI2_CTX_IRQENABLE[1] FE_IRQ	Frame end: This interrupt is triggered on the detection of a frame-end synchronization code into the CSI2 data stream.
CSI2_CTX_IRQSTATUS[2] LS_IRQ	CSI2_CTX_IRQENABLE[2] LS_IRQ	Line start: This interrupt is triggered on the detection of a line-start synchronization code into the CSI2 data stream.
CSI2_CTX_IRQSTATUS[3] LE_IRQ	CSI2_CTX_IRQENABLE[3] LE_IRQ	Line end: This interrupt is triggered on the detection of a line-end synchronization code into the CSI2 data stream.
CSI2_CTX_IRQSTATUS[5] CS_IRQ	CSI2_CTX_IRQENABLE[5] CS_IRQ	CS error: This interrupt is triggered upon detection of a mismatch between the transmitter and receiver checksums (payload).
CSI2_CTX_IRQSTATUS[6] FRAME_NUMBER_IRQ	CSI2_CTX_IRQENABLE[6] FRAME_NUMBER_IRQ	Frame counter reached: This interrupt is triggered when the frame counter reaches its programmable target value.
CSI2_CTX_IRQSTATUS[7] LINE_NUMBER_IRQ	CSI2_CTX_IRQENABLE[7] LINE_NUMBER_IRQ	Line number reached: The programmable line number is received. The modulo feature can be selected (CSI2_CTX_CTRL1.LINE_MODULO). When selected, the interrupt is generated for each line number multiple of the programmed line number (CSI2_CTX_CTRL3.LINE_NUMBER); otherwise, the interrupt is generated only for the line number.
CSI2_CTX_IRQSTATUS[8] ECC_CORRECTION_IRQ	CSI2_CTX_IRQENABLE[8] ECC_CORRECTION_IRQ	ECC was used to correct a 1-bit error (long packets only).

6.4 Camera ISP Functional Description

6.4.1 Camera ISP Block Diagram

Figure 6-53 is the camera ISP top-level block diagram. The camera ISP supports two simultaneous pixel flows, but only one of them can use the Video processing hardware at a time.

See [Section 6.2.3](#) for connectivity configurations and limitations details.

The camera ISP master port is connected to the L3 interconnect, and the slave port is connected to the L4 interconnect (from the camera ISP point of view, commands are output from the camera ISP to the L3 and data are input/output. From the camera ISP point of view, commands are input from the L4 to the camera ISP and data are input/output).

Figure 6-53 shows the camera ISP block diagram.

Figure 6-53. Camera ISP Block Diagram

The camera ISP module comprises the following blocks:

- Timing control: Includes a timing generator and a control-signal generator:
 - The timing generator allows the generation of two clocks that can be used by the external image sensors.

- The control-signal generator allows the generation of signals for strobe flash, mechanical shutter, and global reset.
- Three CSI receivers (one CCP2/MIPI CSI1 and two MIPI CSI2): The CSI receivers communicate with a serial camera through the PHY's and transfers received data to memory or to the Video processing hardware.
- Bridge-lane shifter:
 - The data-lane shifter gives flexibility to the parallel camera connection and permits dynamic reduction of pixel data.
 - The bridge allows higher transfer rates when data is captured from the parallel interface and sent to memory.
- Video-processing front end (VPFE): Comprises the CCDC. This module provides the camera ISP with a powerful and flexible front end interface. It directly affects the input image data:
 - The CCDC provides an interface to image sensors and digital video sources and processes image data.
- Video-processing back end (VPBE): Comprises preview and resizer modules:
 - The preview module is a parameterized hardwired image-processing block whose image-processing functions can be customized for each sensor type to realize good image quality and video frame rates for digital still camera preview displays and video-recording modes.
 - The resizer module provides a means of sizing the input image data to the desired display or video-encoding resolution. Zoom is limited to 4x in both vertical and horizontal directions for each pass. After one (on-the-fly) upscaling pass, the image can be sent to memory and then resent through the resizer.
- Statistics-collection modules (SCM): H3A and histogram modules that provide statistics on the incoming images to help designers of camera systems:
 - The hardware 3A module supports the control loops for AF, AWB, and AE by collecting metrics about RAW image data from the CCDC.
 - The histogram module bins input color pixels, depending on the amplitude, and provide statistics required to implement various 3A (AE/AF/AWB) algorithms and tune the final image/video output. The histogram module can operate on RAW image data from CCDC or memory.
- Central-resource shared buffer logic (CRSBL): Buffers and schedules memory accesses requested by the camera modules
- Circular buffer: Avoids storage of full image frames in the memory when the data must be post and/or preprocessed by software.
- MMU: Performs virtual-to-physical address translation between its interconnect slave and interconnect master access ports

6.4.1.1 Camera ISP Possible Data Paths Inside the module

Data paths inside the camera ISP hardware depend on the image format sourced by the sensor (RAW RGB, YUV4:2:2, JPEG,...).

Table 6-21 lists the modules used for the different data types. The formats described in the columns are the formats at the inputs of the CCDC. It is the internal parallel format.

Table 6-21. Camera ISP Allowed Data Flows for Hardware

Module	8/10 bit RAW from sensor	11/12 bit RAW from sensor	BT 656 8/10 bit	YUV 8/10 bit
CCDC Bridge lane shifter				X
CCDC BT 656 decoder			X	
CCDC DC subtract	X	X	X	X
CCDC Optical Black clamp	X	X		
CCDC Faulty pixel correction	X	X		
CCDC Data formatter	X			

Table 6-21. Camera ISP Allowed Data Flows for Hardware (continued)

Module	8/10 bit RAW from sensor	11/12 bit RAW from sensor	BT 656 8/10 bit	YUV 8/10 bit
CCDC Preview, H3A, Histogram data paths	x			
CCDC Output formatter	x	x	x	x
CCDC Low pass filter	x	x		
CCDC Culling	x	x	x	x
CCDC Alaw	x	x		
CCDC Resizer Datapath			x	x
CCDC Memory Datapath	x	x	x	x
CCDC Shading compensator	x			
Preview	x			
Resizer	x		x	x
H3A	x			
Histogram	x			

6.4.1.1.1 Camera ISP RGB RAW Data

Figure 6-54 shows the data path of images in RAW format.

Figure 6-54. Camera ISP/Data Path/RAW RGB Images

camisp-103

RAW data are processed through the CCDC module and are directly pipelined to the preview engine(1). Another way is to output directly from the CCDC to memory (C) In the preview block; the format is converted from RAW data to YUV4:2:2. The data can be output to memory (4) or pipelined to the resizer (2). The rescaled YUV4:2:2 image is finally stored in memory (3).

In parallel, processed data in the CCDC are used by the H3A module (A), which writes tables of statistics in memory, and by the HIST module (B). The results of the HIST modules are stored in status registers in the HIST module.

NOTE:

- This data path is correct for RAW10 data.
- The data path for RAW8 data is similar to that for RAW10, except that the autofocus module in the H3A does not support RAW8.
- RAW11 data must be sent directly to memory (C).
- RAW12 data must be sent to memory (C) or pixel dynamic must be reduced RAW8 or RAW10 by the bridge-lane shifter module, before the CCDC.
- RAW14 data must be sent to memory (C) or pixel dynamic must be reduced to RAW8 or RAW10 by the bridge-lane shifter module, before the CCDC.

6.4.1.1.2 Camera ISP YUV4:2:2 Data

Figure 6-55 shows the data path of images in YUV4:2:2 format.

Figure 6-55. Camera ISP / Data Path/YUV4:2:2 Images

When the sensor-output format is YUV4:2:2, the CCDC block is directly pipelined to the resizer (1) or output directly to the memory (C). The rescaled YUV4:2:2 images are finally stored in memory (2).

The modules in red in Figure 6-55 are not used when the format is YUV4:2:2.

6.4.1.1.3 JPEG Data

Figure 6-56 shows the data path of images in JPEG format.

Figure 6-56. Camera ISP/Data Path/JPEG Images

When the sensor output format is JPEG, the CCDC block is directly output to the memory (C).

The modules in red in [Figure 6-56](#) are not used when the format is JPEG.

6.4.2 Camera ISP CSI1/CCP2B Receiver

The CSI1 / CCP2B receiver is compatible with the CCP2 specification and the MIPI CSI1 specification.

6.4.2.1 Camera ISP CSI1/CCP2B Receiver Features

The CSI1/CCP2B receiver features are listed below:

- Image from sensor
 - Transfer of pixels and data received by the associated PHY to system memory or to the Video processing hardware
 - Unidirectional data link
 - 1D and 2D addressing mode
 - False synchronization code protection
 - Ping-pong mechanism for double-buffering
 - Support of RGB, RAW, YUV, and JPEG formats
 - Support of DPCM compression and decompression
- Image read from memory
 - RAW formats supported

6.4.2.2 Camera ISP CSI1/CCP2B Receiver Functional Description

6.4.2.2.1 Camera ISP CSI1/CCP2B Overview

[Figure 6-57](#) is the CSI1/CCP2B receiver top-level block diagram. The CSI1/CCP2B receiver takes serial data from a CSI1/CCP2B-compatible image sensor through the selected PHY, converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it to the Video processing hardware or to memory.

The CSI1/CCP2B receiver video-port interface is connected to the Video processing hardware.

Figure 6-57. Camera ISP CSI1/CCP2B Receiver Block Diagram

6.4.2.2.2 Camera ISP CSI1/CCP2B Associated PHY

The CSI1/CCP2B receiver's selected PHY is controlled by 2 bits of the [CCP2_CTRL](#) register:

- The [CCP2_CTRL\[2\]](#) IO_OUT_SEL bit selects the output mode of the PHY which must be set to 1 for parallel.

CAUTION

[CCP2_CTRL\[2\]](#) IO_OUT_SEL bit must be set to 1(parallel mode) after reset and at normal work flow. If not set, it could cause ISP functional stall.

- The [CCP2_CTRL\[10\]](#) INV bit selects the clock edge used to sample data:
 - If [CCP2_CTRL\[10\]](#) INV = 0x0, use the rising edge.
 - If [CCP2_CTRL\[10\]](#) INV = 0x1, use the falling edge.

The CSI1/CCP2B receiver associated configured PHY is controlled by a SCM registers:

SCM.CONTROL_CAMERA_PHY_CTRL

- SCM.CONTROL_CAMERA_PHY_CTRL[4] CSI1_RX_sel:
 - CSIPHY1 data is sent to ISP CSI1/ CCP2B if set to 0
 - CSIPHY2 data is sent to ISP CSI1/ CCP2B if set to 1

For information about initializing the CSIPHY associated with CSI1/CCP2B, see [Section 6.5.2.2, Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver](#).

See [Section 6.2.3](#) for further connectivity schema details.

6.4.2.2.3 Camera ISP CSI1/CCP2B Physical Layer

The CSI1/CCP2B serial interface is a unidirectional differential serial interface with two options for the physical layer: data/clock or data/strobe signals. The physical layer of the CSI1/CCP2B is based on SubLVDS signaling.

CCP2B defines three classes for data transfer between the transmitter and the receiver. [Table 6-22](#) summarizes the CSI1/CCP2B classifications. Class 1 and class 2 do not apply to the MIPI CSI1-compatible mode.

Table 6-22. Camera ISP CSI1/CCP2B Transmitter Classification

Class	Data Transfer Capacity	Signaling Method
Class 0 (CSI1/CCP2)	208 Mbps	Data/clock
Class 1 (CCP2 only)	208 Mbps to 416 Mbps	Data/strobe

Table 6-22. Camera ISP CSI1/CCP2B Transmitter Classification (continued)

Class	Data Transfer Capacity	Signaling Method
Class 2 (CCP2 only)	416 Mbps to 650 Mbps	Data/strobe

6.4.2.2.3.1 Camera ISP CSI1/CCP2B Data/Clock Signaling

Data/clock signaling consists of two parallel signals: data and clock.

- The data signal carries bit-serial data. The CSI1/CCP2B transmitter writes the data on each falling edge of the clock. The data are usually transmitted bytewise, LSB first.
- The data clock signal carries the clock signal. The CSI1/CCP2B transmitter writes the data on each falling edge of the clock. The CSI1/CCP2B receiver reads the data on the rising edge of the clock.

6.4.2.2.3.2 Camera ISP CSI1/CCP2B Data/Strobe Signaling (CCP2 only)

Data/strobe signaling consists of two parallel signals: data and strobe.

- The data signal carries the bit-serial data.
- The data strobe signal carries the strobe signal. It toggles when the data signal does not change state. Either the data signal or the strobe signal changes between two data bits. The data and strobe signals may not change simultaneously. The data and strobe signals are used in the receiver to reconstruct the transmission clock. Both fronts of the reconstructed clock are used to sample the data.

6.4.2.2.4 Camera ISP CSI1/CCP2B Protocol Layer

The CSI1/CCP2B protocol layer defines how image-sensor data are transported to the physical layer.

The CSI1/CCP2B protocol layer transports logical channels, which are composed of frames. A frame comprises embedded data and image-sensor data. Each frame is clearly identified by unique synchronization codes: frame start, frame end, line start, and line end. Image-sensor data can have multiple data types (select the data type in the [CCP2_LCx_CTRL \[7:2\] FORMAT](#) bit field [$x = 0$ to 3]). For details about data types, synchronization code, and FSP encoding/decoding, see [Section 6.2.4.4, Camera ISP CSI1/CCP2 Protocol and Data Formats](#).

6.4.2.2.4.1 Camera ISP CSI1/CCP2B Synchronization Finite State-Machine

[Figure 6-58](#) shows the CSI1/CCP2B receiver finite state-machine (FSM). The CSI1/CCP2B receiver synchronization operates bitwise.

The expected synchronization code order is FSC, LEC, LSC, and LEC...etc., LSC, LEC, LSC, FEC for all data types except JPEG8. For JPEG8, the expected synchronization code order is FSC, FEC.

If the synchronization code order is not respected, the state-machine goes to FalseSyncCode state. Because line length is always a multiple of 32 bits, the LEC and FEC codes are always aligned on a 32-bit boundary. If LEC or FEC is not aligned on a 32-bit boundary, the state-machine goes to LEShiftedSyncCode or FEShiftedSyncCode state. [Figure 6-58](#) shows the synchronization state-machine.

Figure 6-58. Camera ISP CSI1/CCP2B Synchronization State-Machine

camisp-194

In case of synchronization code errors, the CSI1/CCP2B receiver can reinitialize itself. No software intervention is required for most synchronization-code errors:

- Line-end shifted code: The receiver either removes the additional bits or adds dummy bits. The next LS synchronization code resynchronizes the state-machine to normal behavior. A shifted line-end (LE) synchronization code triggers an LE_IRQ event.
- Frame-end shifted code: The receiver either removes the additional bits or adds dummy bits. The next FS synchronization code resynchronizes the state-machine to normal behavior. A shifted frame-end (FE) synchronization code triggers an FE_IRQ event.
- False synchronization code: The current frame is lost. The receiver stops acquiring data, flushes its internal FIFO, and asserts the FSC_IRQ event. The next FS synchronization code resynchronizes the state-machine to normal behavior.

6.4.2.2.4.1.1 Camera ISP CSI1/CCP2B Frames

Structure

Figure 6-59 shows the generic (non-JPEG) description of a CSI1/CCP2B frame with synchronization codes. Each CSI1/CCP2B frame line is composed of a finite number of 32-bit words.

Figure 6-59. Camera ISP CSI1/CCP2B Frame Structure: Non-JPEG Data Format

camisp-195

The period between LEC and new is called the line-blanking period. The time between FEC and new FSC is called the frame-blanking period. The CSI1/CCP2B receiver works with line-blanking periods set to 0 or longer.

[Figure 6-60](#) shows CSI1/CCP2B frame structure for the JPEG8 case. The JPEG stream is composed of a finite number of 32-bit words. LSC and LEC synchronization codes are never used when the CSI1/CCP2B interface transports a JPEG bitstream; only FSC and FEC synchronization codes are used.

Figure 6-60. Camera ISP CSI1/CCP2B Frame Structure: JPEG8 Data Format

FSC	JPEG data (valid data)	FEC	CRC+pad
-----	------------------------	-----	---------

camisp-196

Data

A frame comprises embedded data and image-sensor data. [Figure 6-61](#) shows the location of embedded data and image-sensor data in the frame. The following definitions apply:

- 0 or more start-of-frame (SOF) status lines can be embedded at the beginning of a CSI1/CCP2B frame.
- Image data comprises pixels of the same data formats. It may contain visible or nonvisible pixels.
- 0 or more end-of-frame (EOF) status line(s) can be embedded at the end of a CSI1/CCP2B frame.
- SOF lines, pixel data, and EOF lines do not overlap.

The CSI1/CCP2B receiver does not use the information contained in the status lines. However, it extracts it and stores it in memory for use by the software. [Figure 6-61](#) shows the CSI1/CCP2B data structure.

Figure 6-61. Camera ISP CSI1/CCP2B Data Structure

camisp-197

Embedded information (SOF and EOF lines):

- Embedded information is never compressed (no DPCM).
- Embedded information covers full lines.
- Embedded information is not encoded in the same data format as pixel data. The CSI1/CCP2B receiver extracts embedded information, but does not modify the data format.
- False-synchronization-code protection is implemented; the receiver ensures that the embedded data contains no synchronization codes.

Pixel data:

- Pixel data can be compressed.
- Pixel data comprises pixels of the same data format.
- False-synchronization-code protection is implemented; the receiver ensures that the pixel data contains no synchronization codes.

6.4.2.2.4.1.2 Camera ISP CSI1/CCP2B Logical Channels

Identification

The CCP2B protocol layer transports logical channels. The purpose of logical channels is to separate different data flows that are interleaved in the same data stream. Each logical channel is identified by a unique channel identification number.

The channel identification number is directly encoded in the 32-bit synchronization codes. Logical channels do apply to the MIPI CSI1 compatible mode; only one channel (channel 0) is used.

As shown in [Figure 6-57](#), the CCP2B receiver monitors the channel identification number and demultiplexes the interleaved data streams. The CCP2B receiver supports up to four concurrent logical channels.

The logical channel identifier is coded in the upper 4 bits (bits 4 to 7) of the last byte of the synchronization codes. [Table 6-23](#) summarizes the default logical channel values used for each channel. The CCP2B programming model allows these values to be overwritten.

Table 6-23. Camera ISP CSI1/CCP2B Logical Channel Values in Synchronization Codes

Logical Channel	Value
Logical channel 0	0x0
Logical channel 1	0x1
Logical channel 2	0x2
Logical channel 3	0x3
Logical channel 4	0x4
Logical channel 5	0x5
Logical channel 6	0x6
Logical channel 7	0x7

Muxing

The logical channels are interleaved at the line level or at the frame level. [Figure 6-62](#) shows the possible situations. Each logical channel can use different data formats.

Figure 6-62. Camera ISP CSI1/CCP2B Muxing

FSC_LC1	Data log chan 1	LEC_LC1	CRC+pad

camisp-198

6.4.2.2.5 Camera ISP CSI1/CCP2B Memory Read Channel

The memory channel can perform the following operations:

- Reads data from memory. It is unpacked and DPCM decompressed if necessary.
- Can send the data to the Video processing hardware
- Can send the data back to memory. It can be DPCM compressed and packed before it is sent to memory.

It cannot receive its input data directly from the sensor, and the logical channels are disabled when the memory channel is enabled.

[Table 6-24](#) summarizes supported modes for memory-to-memory operations.

Table 6-24. Camera ISP CSI1/CCP2B Memory-to-Memory Supported Operations

6.4.2.2.5.1 Camera ISP CSI1/CCP2B Read Data From Memory

Figure 6-63 shows the data organization in memory.

Figure 6-63. Camera ISP CSI1/CCP2B Data Organization in Memory

The user chooses the start address and the line length using the [CCP2_LCM_SRC_ADDR](#) and [CCP2_LCM_SRC_OFST](#) registers. The image start address normally must point to the beginning of a line because of packing constraints. However it does not necessarily point to the first line of the frame in memory. The [CCP2_LCM_VSIZE](#) [27:16] COUNT bit field specifies the total line count to be read from memory.

It is also possible to skip a certain pixel count ([CCP2_LCM_HSIZE](#) [11:0] SKIP) from the start of the line. However, they are not sent to the video port or back to memory. The [CCP2_LCM_HSIZE](#) [27:16] COUNT bit field specifies the horizontal size of the image. The pixels after the right boundary of the image are not read from memory.

When data are sent to the video port, throughput is imposed by the selected video port clock. Otherwise, it is imposed by the selected interconnect read port clock. The interconnect read rate can be throttled (limiting the maximum data read speed for memory-to-memory operation) using the [CCP2_LCM_CTRL](#) [4:3] READ_THROTTLE bit field. Therefore, it is possible to read the unused data at a higher rate than the used video port data rate. This provides better performance than framing the image in the Video processing hardware.

The data storage format in memory is defined by the [CCP2_LCM_CTRL](#) [18:16] SRC_FORMAT, and [CCP2_LCM_CTRL](#) [23] SRC_PACK registers.

Not all IO format combinations are valid. See [Table 6-24](#) and [Table 6-25](#) for more information.

Figure 6-64 shows how data are packed in memory. Pixel order (left to right in the image) is alphabetical (a,b,c). Therefore, data storage is little endian.

Figure 6-64. Camera ISP CSI1/CCP2B Data Organization in Memory Continued

camisp-206

Table 6-26 summarizes the storage reduction and image width restrictions when data packing is used.

Table 6-26. Camera ISP CSI1/CCP2B Data Packing Benefit and Constraints

	Bits Per Pixel		Storage Reduction	Width Multiple ⁽¹⁾
	Packed	Unpacked		
RAW6	6	8	25%	16
RAW7	7	8	13%	32
RAW8	8	8	0%	4
RAW10	10	16	38%	16
RAW12	12	16	25%	8

⁽¹⁾ In continuous mode, lines must be multiples of 128 bits. In 2D mode, lines must start on 128-bit boundaries.

6.4.2.2.5.2 Camera ISP CSI1/CCP2B Memory Read Port Burst Generation

The hardware always uses the largest possible burst size according to the setup. The amount of data read from memory can be higher than what is actually used by the CCP2B receiver. Only full 64-bit words are read. [Figure 6-65](#) shows the data organization in memory.

Figure 6-65. Camera ISP CSI1/CCP2B Data Organization in Memory 3

camisp-207

NOTE:

- A minimum burst size of 2 must be selected for correct operation.
- HWORDS must be paired for correct operation.

[Figure 6-64](#) shows the relationship between the different parameters controlling the burst generation. The

[CCP2_LCM_SRC_ADDR](#) register address of the first data to read is aligned to a 32-byte boundary. The read port fetches [CCP2_LCM_PREFETCH](#) [13:3] HWORDS of 64-bit words per line using the longest possible burst computed from the [CCP2_LCM_CTRL](#) [7:5] BURST register and the remaining data to be fetched. When the CCP2B receiver is configured to fetch more data than required, extra data are dropped internally.

6.4.2.2.5.3 Camera ISP CSI1/CCP2B Video Port

The video port always receives unpacked data. It can be enabled using the [CCP2_LCM_CTRL](#) [2] DST_PORT register. Its clock can be selected with the [CCP2_CTRL](#) [9:8] VP_OUT_CTRL register.

The data format used by the video port is defined by the [CCP2_LCM_CTRL](#) [26:24] DST_FORMAT register. See [Table 6-25](#) for a list of supported modes.

6.4.2.2.5.4 Camera ISP CSI1/CCP2B Encode, Pack, and Store Data

This stage is used only when data are sent to memory. Memory destination is selected using the [CCP2_LCM_CTRL](#) [2] DST_PORT register. The output data format is defined by the [CCP2_LCM_CTRL](#) [26:24] DST_FORMAT, and [CCP2_LCM_CTRL](#) [31] DST_PACK registers. Not all possible combinations are supported. See [Table 6-24](#) for details.

The destination address and offset for the output data of the memory channel are set by the [CCP2_LCM_DST_ADDR](#) and [CCP2_LCM_DST_OFST](#) registers.

Because of alignment constraints on the interconnect port, the output image width restrictions in [Table 6-27](#) apply.

Table 6-27. Camera ISP CSI1/CCP2B Output Width Restrictions in Memory-to-Memory Operation

Format	Bits/pix	Width Multiple of ⁽¹⁾	Note
RAW6	8	1	Full 32-bit words are written at the end of the line. This last word can eventually include 0s.
RAW6 PACK	6	1	
RAW7	8	1	
RAW7 PACK	7	1	
RAW8	8	1	
RAW10	16	1	
RAW10 PACK	10	16	
RAW12	16	1	Same constraints as RAW8
RAW12 PACK	12	8	

⁽¹⁾ In continuous mode, lines must be multiples of 128 bits. In 2D mode, lines must start on 128-bit boundaries.

For example, when RAW6 packed data are written to memory, any output width is allowed. However, only full 32-bit words are written to memory. This eventually overwrites some data in memory at the end of a line.

The supported output width is restricted for packed RAW10 and RAW12 data because of the particular bit ordering in those formats (see [Figure 6-64](#)).

When the DST_OFST is set to 0, start of lines will be aligned on 4-byte boundaries. When DST_OFST != 0, data are aligned on 32-byte boundaries.

NOTE: The RAW6 and RAW7 data formats do not apply to the MIPI CSI1 compatible mode.

6.4.2.2.6 Camera ISP CSI1/CCP2B Image Data Operating Modes and Alignment Constraints

The CCP2B receiver interface has several image-data operating modes, summarized in [Table 6-28](#). The EXPx formats ($x = 8, 16$, or 32) are used to expand data up to $8, 16$, or 32 bits by padding data with 0s. The Data Size Increase in the Memory column indicates memory overhead versus format without data expansion or/and DPCM compression.

Table 6-28. Camera ISP CSI1/CCP2B Image Data Operating Modes and Alignment Constraints

CCP2_LCx_CT RL[7:2] Format	CCP2 Data Format	Bits per Pixel (bpp) (when sending data to memory, N/A when sending to VP)	Data Size Increase in Memory (when negative, data compression present)	2D Mode Availability ⁽¹⁾	Comments
0x0	YUV422 big endian	16	0%	Yes	
0x1	YUV422 little endian	16	0%	Yes	
0x2	YUV420	12	0%	Yes	
0x3	YUV422 + VP	N/A, data are sent to VP, YUV422 + VP = RAW8 + VP	N/A	Yes	
0x3	RAW8 + VP	N/A, data are sent to VP, YUV422 + VP shall be used to output RAW8 + VP to memory	N/A	Yes	
0x4	RGB444 + EXP16	16	50%	Yes	
0x5	RGB565	16	0%	Yes	
0x6	RGB888	24	0%	Yes	
0x7	RGB888 + EXP32	32	33%	Yes	
0x8	RAW6 + EXP8	8	33%	Yes	
0x9	RAW6 + DPCM10 + EXP16	16	167%	Yes	DPCM decompression
0xA	RAW6 + DPCM10 + VP	N/A, data are sent to VP	N/A	Yes	DPCM decompression
0xB	RAW10 - RAW6 DPCM	6	-40%	Yes	DPCM compression
0xC	RAW7 + EXP8	8	14%	Yes	
0xD	RAW7 + DPCM10 + EXP16	16	128%	Yes	DPCM decompression
0xE	RAW7 + DPCM10 + VP	N/A, data are sent to VP	N/A	Yes	DPCM decompression
0xF	RAW10 - RAW6 DPCM + EXP8	8	-25%	Yes	DPCM compression
0x10	RAW8, this mode can be used to output RAW6 and RAW7	8	0%	Yes	
0x11	RAW8 + DPCM10 + EXP16	16	100%	Yes	DPCM decompression
0x12	RAW8 + DPCM10 + VP	N/A, data are sent to VP	N/A	Yes	DPCM decompression
0x13	RAW10 - RAW7 DPCM	7	-30%	Yes	DPCM compression
0x14	RAW10	10	0%	Yes	
0x15	RAW10 + EXP16	16	60%	Yes	
0x16	RAW10 + VP	N/A, data are sent to VP	N/A	Yes	
0x17	RAW10 - RAW7 DPCM + EXP8	8	-20%	Yes	
0x18	RAW12	12	0%	Yes	

⁽¹⁾ If 2D mode is available, there are no supplementary constraints on data width. 2D mode is not applicable when sending to video port (VP).

**Table 6-28. Camera ISP CSI1/CCP2B Image Data Operating Modes and Alignment Constraints
(continued)**

CCP2_LCx_CTRL[7:2] Format	CCP2 Data Format	Bits per Pixel (bpp) (when sending data to memory, N/A when sending to VP)	Data Size Increase in Memory (when negative, data compression present)	2D Mode Availability <small>(1)</small>	Comments
0x19	RAW12 + EXP16	16	33%	Yes	
0x1A	RAW12 + VP	N/A, data are sent to VP	N/A	Yes	
0x1B	RAW10 - RAW8 DPCM	8	-20%	Yes	DPCM decompression
0x1C	JPEG, 8-bit data	N/A	0%	Yes	
0x1D	JPEG, 8-bit data + FSP	N/A	0%	Yes	
0x1E	RAW10 - RAW8 DPCM	8	-20%	Yes	Data right shift
0x1F	RAW8 DPCM12-RAW12 + VP	N/A, data are sent to VP	N/A	Yes	
0x20	RAW10 - RAW8 ALAW	8	-20%	Yes	
0x21	RAW8 DPCM10 - ALAW	8	-20%	Yes	

NOTE:

- Padding data of a 32 bit pixel data stream is handled the same way regardless of the programmed format. Therefore, no storage increase/decrease because it is not compressed/decompressed.
 - EXP8 = Data expansion to 8 bits, padding with zeros
 - EXP16 = Data expansion to 16 bits, padding with alpha or zeros
`CCP2_LCx_CTRL[15:8]` ALPHA can be used to set an alpha value.
 For RGB444 + EXP16:
 - `data_out[31:28] = ALPHA [3:0]`
 - `data_out[15:12] = ALPHA [3:0]`
 - EXP32 = Data expansion to 32 bits, padding with alpha
`CCP2_LCx_CTRL[15:8]` ALPHA can be used to set an alpha value.
 For RGB888 + EXP32: `data_out [31:24] = ALPHA [7:0]`
 - FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
 - VP = Output to the video-preprocessing hardware is enabled. The programmer must ensure that only one logical channel is enabled to the video preprocessing hardware. The behavior of the hardware is unpredictable if several logical channels to the video preprocessing hardware are enabled simultaneously.
 - DPCM10 = Data decompression to 10 bits. Only applies to the RAW6, RAW7 and RAW8 data formats. Disabled if `CCP2_CTRL[4]` MODE = 0.
 - Padding is handled the same way regardless of the programmed format.
-

6.4.3 Camera ISP CSI2 Receiver

NOTE: There are two CSI2 receivers in the ISP with same functionality. For reading ease, the following section applies to both CSI2A and CSI2C receivers.

6.4.3.1 Camera ISP CSI2 Receiver Features

The CSI2 receiver module is a master on the L3 interconnect for storing data in memory and a slave on the L4 interconnect for register access.

The main features of the CSI2 receiver module are:

- Transfer pixels and data received by the PHY to the system memory
- Unidirectional data link
- Minimum of one and maximum of two configurable data links in addition to clock signaling
- Maximum data rate of 1000 Mbps per data pair
- Data merger for 2-data lane configuration
- Error detection and correction by the protocol engine
- DMA engine integrated with dedicated FIFO
- Streaming 1D and 2D addressing modes
- Up to eight contexts to support eight dedicated configurations of virtual channel ID and data types
- Ping-pong mechanism for double-buffering
- JPEG support for unknown length transfer (no extraction of the thumbnail)
- All primary and secondary MIPI-defined formats are supported (RGB, RAW, and YUV)
- Storage in progressive mode for interlaced stream (using line numbering)
- Conversion of the RGB formats
- Decompression of the RAW formats
- RAW frame transcoding. Including DPCM and A-law compression
- Configuration of PHY
- Fully configurable interface of the PHY: position of the clock and data and order of \pm differential signals for each pair
- Support of DPCM decompression

6.4.3.2 Camera ISP CSI2 Receiver Block Diagram

Figure 6-66 is the block diagram of the CSI2 receiver connected to the PHY.

Figure 6-66. Camera ISP CSI2 Receiver Block Diagram

camisp-238

6.4.3.3 Camera ISP CSI2 Physical Layer Lane Configuration

The CSI2 serial interface is a unidirectional differential serial interface with data/clock for the physical layer. The CSI2 PHY is based on the MIPI DPHY Specification version 1.0.

The maximum CSI2 receiver data transfer capacity is 1000 Mbps per data lane.

Data-clock signaling consists of four to six signals: one or two data lanes and one clock lane:

- The data signal carries the bit-serial data. The CSI2 transmitter in the image sensor sends the data in-quadrature with the DDR clock in HS mode; otherwise, the clock is extracted from the received data in LS mode. Data is transmitted byte-wise, LSB first. The CSI2 PHY receives the data and sends the byte stream to the CSI2 receiver.
- The clock signal carries the DDR clock signal.

Each physical lane can be a data or a clock lane. The clock/data lane must be configured before transmission to indicate the byte order while merging the received bytes into a byte stream.

Lanes are configured through the [CSI2_COMPLEXIO_CFG1](#) register for the associated and configured to the receiver PHY. The CLOCK_POSITION and CLOCK_POL fields configure which lane transmits the clock and define its polarity.

NOTE: If the parallel camera sensor and other camera sensor (CCP2 or CSI2) are connected to the same CSIPHY, the CONTROL_CAMERAx_PHY_CAMMOD bit must be set for CCP2 or CSI2 mode, respectively, (even if only one pair is used as GPI for CPI mode). In that case, the corresponding [CSI2_COMPLEXIO_CFG1](#).DATAx_POSITION bit must be set to 0x0 for the lane used in GPI mode.

The [CSI2_COMPLEXIO_CFG1](#) register also contain a bit field affecting PHY power management.

For information about initializing the CSIPHY associated with CSI2, see [Section 6.5.2.2, Camera ISP CSIPHY Initialization for Work With CSI2 Receiver](#).

6.4.3.4 Camera ISP CSI2 ECC and Checksum Generation

The CSI2 receiver includes an ECC in the packet header and a checksum in the packet footer for long-packet transmission. These two fields can be used to detect and/or correct errors in the received packet.

6.4.3.4.1 Camera ISP CSI2 ECC

To detect and correct transmission errors of the header of short and long packets, an 8-bit ECC is included in the header of packets (short and long packet).

The ECC concerns all the fields for a short packet (data ID and short-packet data field) and the packet header for long packet (data ID and word count). The ECC can only correct one error. Additional errors cannot be repaired, but they are flagged.

The CSI2 receiver ECC is compared against the CSI2 transmitter ECC embedded in the bit stream. If the ECC does not match, an interrupt is triggered to the host CPU.

For both long and short packets, the correction is always done if there is only one error per packet.

An ECC error with or without correction can be reported at two levels, depending on the type of packet.

[Table 6-29](#) describes the field where events are logged. Logging cannot be disabled, but users can set the corresponding bit in the [CSI2_IRQENABLE](#) and [CSI2_CTX_IRQENABLE](#) registers to prevent event generation at a higher level.

Table 6-29. Camera ISP CSI2 ECC Event Logging

	Short Packet	Long Packet
With correction	Global CSI2_IRQSTATUS[12] ECC_CORRECTION_IRQ	Context CSI2_CTX_IRQSTATUS[8] ECC_CORRECTION_IRQ
Without correction	Global CSI2_IRQSTATUS[11] ECC_NO_CORRECTION_IRQ	Global CSI2_IRQSTATUS[11] ECC_NO_CORRECTION_IRQ

The ECC check can be disabled (short and long packet) by writing 0 in the [CSI2_CTRL\[2\]](#) ECC_EN bit field. Writing 1 enables the ECC check.

6.4.3.4.2 Camera ISP CSI2 Checksum

To detect errors in transmission of the payload of long packets, a 16-bit CRC checksum is computed on the payload of the long packets in the transmitter. This CRC is stored in the packet footer. A CRC is also computed in the CSI2 receiver. If the checksums do not match, an event is triggered to the host CPU.

CRC errors are logged in the CS IRQ field of the corresponding context register, [CSI2_CTX_IRQSTATUS](#). Logging cannot be disabled, but users can set the corresponding bit in the [CSI2_CTX_IRQENABLE](#) register to prevent event generation at a higher level.

The CRC check can be disabled for a specific context by writing 0 in the [CSI2_CTX_CTRL1\[5\]](#) CS_EN bit. Writing 1 enables the CRC check.

6.4.3.5 Camera ISP CSI2 RAW Image Transcoding with DPCM and A-law Compression

The CSI2 receiver has a functionality to have an image in raw format transcoded. Transcoding is mainly used to reduce memory footprint and bandwidth when:

- The sensor does not support DPCM compression. So by transcoding A-law and DPCM compressed pixels only occupy 6, 7 or 8-bits/pixel of storage.
- Digital zoom is used. In fact:
 - Data that is not going to be used by further processing does not need to be stored in system memory.
 - Pixels cannot be accessed from random locations in a DPCM compressed frame. Therefore, transcoding avoids memory to memory processing of unused pixels.

[Figure 6-67](#) shows the logical representation of the image transcoding operation. Basically, the steps are as follow:

- Data is extracted from the CSI2 stream

- It is DPCM decompressed if necessary. That's the case when the received stream is DPCM compressed and transcoding has been enabled using the [CSI2_CTx_CTRL1\[27:24\]](#) TRANSCODE register.
- Data send to the video port cannot be compressed: it is intended to be processed by an HW ISP. Data send to system memory could be optionally compressed.
- Internal data is aligned on MSB when the enter the cropping stage:
 - 4 LSBs are 0s when RAW10 data is handled
 - 2 LSBs are 0s when RAW12 data is handled
 - etc...

Figure 6-67. Camera ISP CSI2 RAW Image Transcoding Diagram

[Table 6-30](#) shows the input format provided to the cropping engine for a given pixel format provided by the sensor. Formats not listed in the following table are not supported for transcoding.

Table 6-30. Camera ISP Pixel Format Modes

CSI2_CTx_CTRL2 [9:0] Format	CSI2 Data Format	Cropping Engine Input	DPCM Decomp Enabled	Video Port Enabled
0x028	RAW6	RAW6		
0x068	RAW6 + EXP8			
0x029	RAW7	RAW7		
0x069	RAW7 + EXP8			
0x02A	RAW8	RAW8		
0x12A	RAW8 + VP			Yes
0x02B	RAW10	RAW10		
0x0AB	RAW10 + EXP16			
0x0E8	RAW6 + DPCM10 + VP		Yes	Yes
0x12F	RAW10 + VP			Yes
0x229	RAW7 + DPCM10 + EXP16		Yes	
0x2A8	RAW6 + DPCM10 + EXP16		Yes	
0x2AA	RAW8 + DPCM10 + EXP16		Yes	
0x329	RAW7 + DPCM10 + VP		Yes	Yes
0x32A	RAW8 + DPCM10 + VP		Yes	Yes
0x2Cn	USER_DEFINED_BYTEDI ATA + DPCM10 + EXP16		Yes	
0x34n	USER_DEFINED_BYTEDI ATA + DPCM10 + VP		Yes	Yes

Table 6-30. Camera ISP Pixel Format Modes (continued)

CSI2_CTX_CTRL2 [9:0] Format	CSI2 Data Format	Cropping Engine Input	DPCM Decomp Enabled	Video Port Enabled
0x02C	RAW12	RAW12		
0x0AC	RAW12 + EXP16			
0x12C	RAW12 + VP			
0x36A	RAW8 + DPCM12 + EXP16		Yes	
0x3AA	RAW8 + DPCM12 + VP		Yes	Yes
0x1Cn	USER_DEFINED_BYTEDIATA + DPCM12 + EXP16		Yes	
0x14n	USER_DEFINED_BYTEDIATA + DPCM12 + VP		Yes	
0x3A8	RAW6 + DPCM12 + EXP16		Yes	
0x368	RAW6 + DPCM12 + VP		Yes	Yes
0x369	RAW7 + DPCM12 + EXP16		Yes	
0x3A9	RAW7 + DPCM12 + VP		Yes	Yes
0x02D	RAW14	RAW14		
0x0AD	RAW14 + EXP16			
0x12D	RAW14 + VP			Yes

Image cropping parameters are controlled by software. [Figure 6-68](#) provides a graphical representation of the cropping operation.

Figure 6-68. Camera ISP CSI2 Frame Cropping

NOTE: Hardware does not check for validity of the settings. The following rules must be respected:

- [CSI2_CTX_TRANSCODEH\[12:0\]](#) HSKIP+ [CSI2_CTX_TRANSCODEH\[28:16\]](#) HCOUNT = image width
- [CSI2_CTX_TRANSCODEV\[12:0\]](#) VSKIP+ [CSI2_CTX_TRANSCODEV\[28:16\]](#) VCOUNT = image height

Furthermore, [CSI2_CTX_TRANSCODEV\[28:16\]](#) HCOUNT must comply with the following alignment constraints. Undefined behavior occurs otherwise. [Table 6-31](#) shows the ranscode alignment constraints

Table 6-31. Camera ISP CSI2 Transcode Alignment Constraints

CSI2_CTx_CTRL[27:24]] TRANSCODE value	Transcode	HCOUNT must be multiple of
0x0	Disabled	1
0x1	DPCM10 RAW8	1
0x2	DPCM12 RAW8	1
0x3	ALAW10 RAW8	1
0x4	RAW8	1
0x5	RAW10 + EXP16	1
0x6	RAW10	4
0x7	RAW12 + EXP16	1
0x8	RAW12	2
0x9	RAW10 + EXP16	4

Table 6-32 shows the possible combinations between input and output formats supported by the transcoding engine. The Transcode column corresponds to the [CSI2_CTx_CTRL1\[27:24\]](#) TRANSCODE register of a context.

Table 6-32. Camera ISP CSI2 Supported Transcoding Output Formats

Cropping Engine Output	Transcode		Supported	Cropping Engine Output	Transcode		Supported

	6	RAW10			6	RAW10	
	7	RAW12 + EXP16			7	RAW12 + EXP16	
	8	RAW12			8	RAW12	

Table 6-32. Camera ISP CSI2 Supported Transcoding Output Formats (continued)

Cropping Engine Output	Transcode	Supported	Cropping Engine Output	Transcode	Supported
9	RAW14			9	RAW14

For RAW10 and RAW12, Software could choose among packed and non packed storage. A-law and DPCM compressed pixels are stored as RAW8 data: each RAW8 container holds a compressed data point. Similarly, RAW data is send over the video port . Enabling of the OCP / video port is controlled as usual by the [CSI2_CTX_CTRL2\[9:0\]](#) FORMAT and [CSI2_CTRL\[11\]](#) VP_ONLY_EN and [CSI2_CTX_CTRL1\[2\]](#) VPFORCE registers.

In order to enable transcoding, The software configures the context normally and in addition, configures the framing using the [CSI2_CTX_TRANSCODEV](#) and [CSI2_CTX_TRANSCODEH](#) registers. The software defines the after transcoding with the [CSI2_CTX_CTRL1\[27:24\]](#) TRANSCODE register.

6.4.3.6 Camera ISP CSI2 Short Packet

There are two types of short packets in the CSI2 receiver:

- Synchronization short packet: Used by the protocol engine to synchronize frame and line (data ID from 0x0 to 0x7)
- Generic short packet: User-dependent; not treated by the protocol engine (data ID from 0x8 to 0xF)

When a generic short packet is received by the CSI2 receiver, the ECC check is performed if it is enabled (see [Section 6.4.3.4.1, ECC](#)). Then, the short packet is written in the [CSI2_SHORT_PACKET\[23:0\]](#) SHORT_PACKET bit field. The ECC field is deleted from the short packet. [Figure 6-69](#) shows the SHORT_PACKET field format.

Figure 6-69. Camera ISP CSI2 SHORT_PACKET Field Format

An event is logged when a short packet is stored in the SHORT_PACKET_IRQ bit in the [CSI2_IRQSTATUS\[13\]](#) register. Logging cannot be disabled, but users can set the corresponding bit in the [CSI2_IRQENABLE](#) register to prevent event generation at a higher level.

The application reads the [CSI2_SHORT_PACKET](#) register before the next short packet with a code between 0x8 and 0xF. There is a single register for capturing the generic short packet, because no data type in it is associated with context.

6.4.3.7 Camera ISP CSI2 Virtual Channel and Context

The CSI2 protocol layer transports virtual channels. The purpose of virtual channels is to separate different data flows interleaved in the same data stream. Each virtual channel is identified by a unique channel identification number in the packet header. This channel identification number is encoded in the 2-bit code.

The CSI2 receiver monitors the channel identifier number and demultiplexes the interleaved data streams. The CSI2 receiver supports up to four concurrent virtual channels.

The CSI2 receiver supports eight contexts to control the four possible virtual channels and the different data transmitted through them. A context is linked to a specific data type transported by a given virtual channel. The following two bit fields permit configuration of a context:

- [CSI2_CTX_CTRL2\[12:11\]](#) VIRTUAL_ID: Configures the virtual ID linked to the current context
- [CSI2_CTX_CTRL2\[9:0\]](#) FORMAT: Configures the data format linked to the current context

[Figure 6-70](#) shows the relationships between virtual channels and contexts.

Figure 6-70. Camera ISP CSI2 Virtual Channel to Context

Each context consists of eight registers: six registers to control the corresponding context and two to log and enable events from the context. All registers in a context can be modified at any time; however, modifications apply only from the start of the following frame.

A context can be enabled independently by writing 1 in the [CSI2_CTX_CTRL1\[0\]](#) CTX_EN bit field; writing 0 disables the corresponding context.

When acquiring frames on a context, users can write the number of frames to capture in the [CSI2_CTX_CTRL1\[15:8\]](#) COUNT bit field. Acceptable values are 0:255; 0 stands for infinite capture (no count). After each frame acquired, the count value is decremented by 1. When the count value reaches 0, the [CSI2_CTX_IRQSTATUS\[6\]](#) FRAME_NUMBER_IRQ event is set and the CTX_EN bit is set to 0. To write a value in the COUNT bit field, the [CSI2_CTX_CTRL1\[4\]](#) COUNT_UNLOCK bit must be set to 1. If the COUNT_UNLOCK value is 0, a write in the COUNT bit field has no effect.

The [CSI2_CTX_CTRL3\[15:0\]](#) LINE_NUMBER bit field configures the generation of the [CSI2_CTX_IRQSTATUS\[7\]](#) LINE_NUMBER_IRQ event. The [CSI2_CTX_CTRL1\[1\]](#) LINE_MODULO bit configures how the LINE_NUMBER event is generated:

- 0: The event is generated one time by frame.
- 1: The event is generated modulo LINE_NUMBER (the event can be generated more than once in a frame).

During a frame capture, the [CSI2_CTX_CTRL2\[31:16\]](#) FRAME_NUMBER bit field shows the number that identifies the frame received.

6.4.3.8 Camera ISP CSI2 DMA Engine

The CSI2 receiver integrates its own DMA engine with dedicated FIFO.

Global DMA configuration (single access, non-streaming and posted writes) is common to the eight channels and is defined in the [CSI2_CTRL](#) register. Configuration of the ping-pong address and the offset between lines is specific for a given context; therefore, each context has its own DMA configuration registers.

The DMA engine supports the following requests:

- Single write

When an element (the size depends on the data type) is present in the FIFO, the DMA engine initiates a single write.

All single requests sent to the interconnect are back-to-back requests with no idle, if the FIFO has enough data to supply the DMA.

The DMA starts to write in memory using the [CSI2_CTX_DAT_PING_ADDR\[31:5\]](#) ADDR bit field for the first frame to be transferred and then uses the [CSI2_CTX_DAT_PONG_ADDR\[31:5\]](#) ADDR bit field and the ping address alternately. So, the first frame uses the ping address, the second frame uses the pong address, the third frame uses the ping address, and so on.

The **CSI2_CTx_CTRL1[3]** PING_PONG status bit indicates whether the ping address (**CSI2_CTx_DAT_PING_ADDR**) or the pong address (**CSI2_CTx_DAT_PONG_ADDR**) was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in the **CSI2_CTRL[0]** IF_EN register, the pixel data is written in the ping buffer and **CSI2_CTx_CTRL1[3]** PING_PONG = PONG. When the number of FECs received equals the value programmed in the **CSI2_CTx_CTRL1[23:16]** FEC_NUMBER bit field, the pixel data are written in the pong buffer and **CSI2_CTx_CTRL1[3]** PING_PONG = PING. **CSI2_CTx_CTRL1[3]** PING_PONG toggles after the **CSI2_CTx_CTRL1[23:16]** FEC_NUMBER FEC sync code with the virtual channel ID defined is received in the **CSI2_CTx_CTRL2[12:11]** VIRTUAL_ID bit field.

The **CSI2_CTx_CTRL1[23:16]** FEC_NUMBER bit field must be set as follows:

- In progressive mode, set to 1.
- In interlaced mode, set to the number of interlaced frames to recreate a progressive image in the PING_PONG buffer.

6.4.3.8.1 Camera ISP CSI2 Progressive Frame to Progressive Storage

After each line, a new start line address is computed, depending on the value of the **CSI2_CTx_DAT_OFST[15:5]** OFST bit field:

- If OFST = 0, the new line starts immediately after the last pixel (data are written contiguously in memory).
- Otherwise, the OFST value sets the offset between the first pixel of the previous line and the first pixel of the current line in memory.

For the ping frame:

```
@Line0 = CSI2_CTx_DAT_PING_ADDR @Line1 = @Line0 + CSI2_CTx_DAT_OFST
@Line2 = @Line1 + CSI2_CTx_DAT_OFST
```

For the pong frame:

```
@Line0 = CSI2_CTx_DAT_PONG_ADDR @Line1 = @Line0 + CSI2_CTx_DAT_OFST
@Line2 = @Line1 + CSI2_CTx_DAT_OFST
```

6.4.3.8.2 Camera ISP CSI2 Interlaced Frame to Progressive Storage

The mode is functional only when the line numbers are transmitted. It is automatically enabled without setting.

For the ping frame:

```
@LineX = CSI2_CTx_DAT_PING_ADDR + CSI2_CTx_DAT_OFST * Line_Number
```

For the pong frame:

```
@LineX = CSI2_CTx_DAT_PONG_ADDR + CSI2_CTx_DAT_OFST * Line_Number
```

[Figure 6-71](#) shows how data are stored in memory regarding DMA configuration.

Figure 6-71. Camera ISP CSI2 Pixel Data Destination Setting in Progressive and Interlaced Mode

6.4.3.9 Camera ISP CSI2 PHYs

The two PHYs in the device act as the interface between the transmitter (camera sensor) and the receivers inside the camera ISP. The modules transform the bit stream divided into one or two serial data lanes into a bit stream compatible with the CSI2 receiver and one clock lane. The two CSIPHY1 and CSIPHY2 have identical functionality, only difference is that CSIPHY1 is limited to one data line. Figure 6-72 shows the CSIPHY overview diagram.

Figure 6-72. Camera ISP CSI2 PHY Overview

The **CSI2_COMPLEXIO1_IRQSTATUS** register logs the CSIPHY event. The events that occur are:

- Line power state change (all lanes in ULPM, at least one lane exits ULPM, etc.)
- Error on one lane

NOTE: For information about initializing the CSIPHY associated with CSI2, see [Section 6.5.2.2, Camera ISP CSIPHY Initialization for Work With CSI2 Receiver](#).

Both CSI2A and CSI2C receivers embed a registers to configure/read some PHY parameters:

- The **CSI2_COMPLEXIO_CFG1** register reports completion of reset on the different parts of the module and configures timing parameters.

The CSIPHYs have three power modes: on, off, and ULP (ultra-low power). These modes can reflect the ON or ULP power state of the three differential lines if the [CSI2_COMPLEXIO_CFG1\[24\]](#) PWR_AUTO bit is set to 1. If the PWR_AUTO bit is at reset value (0), the PHY power state is controlled by the [CSI2_COMPLEXIO_CFG1\[28:27\]](#) PWR_CMD bit field, which directly defines the power state. [Figure 6-73](#) shows the PHY power finite state machine (FSM).

Figure 6-73. Camera ISP CSIPHY Power FSM

camisp-253

Another register, [CSI2_TIMING](#), is used to control the power state of the CSIPHY module with regards to the differential line state. This register is used to control the mode of the CSIPHY (RxMode or NoRxMode) and the delay between all the differential lines on STOP state and CSIPHY on NoRxMode. The [CSI2_TIMING\[15\]](#) FORCE_RX_MODE_IO1 bit field sets the CSIPHY in RxMode or in NoRxMode (stopped mode). The FORCE_RX_MODE_IO1 bit is automatically reset to 0 by hardware when the counter ends and the FSM returns to NoRxMode. Three bit fields ([CSI2_TIMING\[14\]](#) STOP_STATE_X16_IO1, [CSI2_TIMING\[13\]](#) STOP_STATE_X4_IO1, and [CSI2_TIMING\[12:0\]](#) STOP_STATE_COUNTER_IO1) configure the delay between line stop mode and CSIPHY stop mode. The delay represents the number of functional clock (CAM_FCLK) cycles and can be calculated as follows:

Total delay in CAM_FCLK cycle = [CSI2_TIMING.STOP_STATE_COUNTER_IO1](#) x (1 + [CSI2_TIMING.STOP_STATE_X16_IO1](#) x 15) x (1 + [CSI2_TIMING.STOP_STATE_X4_IO1](#) x 3).

[Table 6-33](#) lists the possible values of the delay, in terms of the CAM_FCLK cycles, depending on the values of the STOP_STATE_X16_IO1 and STOP_STATE_X4_IO1 bits.

Table 6-33. Camera ISP CSI2 Possible Time-Out Value for RxMode Counter

STOP_STATE_X16_IO1	STOP_STATE_X4_IO1	Possible Delay Value (in Functional Clock Cycles)
0x0	0x0	8191 (with step of 1)
0x0	0x1	32764 (with step of 4)
0x1	0x0	131056 (with step of 16)
0x1	0x1	524224 (with step of 64)

The state-machine controlling the RxMode is presented in [Figure 6-74](#).

Figure 6-74. Camera ISP CSI2 RxMode and StopState FSM

6.4.3.10 Camera ISP CSI2 Data Decompression

The data compression technique used is differential pulse code modulation (DPCM) and pulse code modulation (PCM).

The CSI2 receiver performs on-the-fly decompression. The decompressed data is either passed to the Video processing hardware or stored in memory.

The data compression method is lossy and does not require any information outside the current encoded/decoded line. This means that all the image lines can be encoded/decoded separately.

There are two different predictors used:

- The simple predictor

This predictor uses only the previous same color component value as a prediction value. Therefore, only two-pixel memory is required.

- The advanced predictor

This predictor uses four previous pixel values, when the prediction value is evaluated. This means that also the other color component values are used, when the prediction value has been defined.

The preferable usage is that simple predictor is used with 10 bits to 8 bits conversion (10 8 10) and the advanced predictor is used with 10 bits to 7 bits and 10 bits to 6 bits conversions (10 7- 10 and 10 6 10). The advanced predictor gives slightly better prediction for pixel value and so the image quality can be improved with it. The simple predictor is very simple and so the processing power and the memory requirements are reduced with it, when the image quality anyway is high enough.

To select DPCM decompression predictor for CSI2 Interface, set the [CSI2_CTx_CTRL2\[10\]](#) DPCM_PRED to 1 for simple predictor or to 0 for advanced predictor.

6.4.3.11 Camera ISP CSI2 EndOfFrame and EndOfLine Pulses

The CSI2 receiver generates two signals to qualify the last pixel of a frame and the last pixel of a line.

Software can enable/disable generation of those signals for each context using the [CSI2_CTx_CTRL1\[7\]](#) EOF_EN and [CSI2_CTx_CTRL1\[6\]](#) EOL_EN registers.

6.4.4 Camera ISP Timing Control

6.4.4.1 Camera ISP Timing Control Features

The timing-control module provides two clocks (cam_xclka and cam_xclkb) that can be used by external camera modules. It also generates the control signals (cam_strobe and cam_shutter) for the flash pre-strobe, flash strobe, and mechanical shutters.

The timing-control module includes a timing generator and a control-signal generator.

6.4.4.2 Camera ISP Timing Control Overview

[Figure 6-75](#) shows a block diagram of the timing-control module.

Figure 6-75. Camera ISP Timing Control block diagram

6.4.4.2.1 Camera ISP Timing Control Generator

The timing control generates the cam_xclka and cam_xclkb clocks based on the CAM_MCLK frequency, which can be up to 216 MHz. The cam_mclk is used only by the clock generator; the cam_xclka and cam_xclkb clocks are not used internally by the camera ISP. The clock divider is programmable.

The possible frequencies of cam_xclka and cam_xclkb and their respective configurations are described in [Section 6.3.1.1.3, Clock Configuration](#).

[Table 6-34](#) summarizes the possible frequencies as a function of the divisor values.

6.4.4.2.2 Camera ISP Timing Control Control-Signal Generator

The control-signal generator generates the pre-strobe, strobe, and shutter signals: cam_strobe and cam_shutter. [Figure 6-76](#) shows the principle of control-signal generation.

Figure 6-76. Camera ISP Timing Control Control-Signal Generation

camisp-033

The control-signal generator gathers precise timings for the cam_strobe and cam_shutter signals, to assert and deassert the signals at known times. The timing-control-signal generator can be synchronized either on the vertical synchronization signal coming from the CSI2A (VP_VS from CSI2A), CSI2C (VP_VS from CSI2C), CSI1/CCP2B (VP_VS from CSI1/CCP2B), or PARALLEL interface (cam_vs), or on an externally-generated cam_global_reset signal.

A multiplexer controls which of the CSI2A, CSI1/CCP2B or CSI2C, and PARALLEL interface drives control-signal generation. This multiplexer can also select the externally-generated cam_global_reset signal as the trigger event. The [TCTRL_CTRL \[31\]](#) GRESETDIR register defines the direction of the cam_global_reset signal.

- The external generated cam_global_reset is used as a trigger when [TCTRL_CTRL \[31\]](#) GRESETDIR = 0 and [TCTRL_CTRL\[27:28\]](#) INSEL = 3.
- The internally generated cam_global_reset is used as a trigger when [TCTRL_CTRL \[31\]](#) GRESETDIR = 1 and [TCTRL_CTRL\[27:28\]](#) INSEL = 3.

- If the PARALLEL interface is selected, control-signal generation works for both ITU and SYNC modes and on both output ports: video port and shared-buffer-logic (SBL) port.
- If the CSI2A or CSI1/CCP2B/CSI2C interface is selected, control-signal generation works on both output ports: video port and interconnect port.

The cam_global_reset signal can also be generated internally by the control-signal generator under software control. In this case, the prestrobe and shutter signals are synchronized on the internally generated cam_global_reset signal. The multiplexer controls whether control-signal generation must be triggered by the internal or external cam_global_reset signal.

The prestrobe-, strobe-, and shutter-control signals can be individually enabled at any time. These signals must not be disabled by software.

The clock divider generates the CNTCLK clock based on the cam_mclk clock. The clock divider is programmable. [Table 6-34](#) summarizes the possible frequencies as a function of the divisor values.

Table 6-34. Camera ISP Timing Control Control-Signal Generator: CNTCLK Frequencies

Divisor Value TCTRL_CTRL [18:10] DIVC	CNTCLK Clock
0 (default)	Clock gated. No clock.
1	216 MHz, free-running.
2	108 MHz
3	72 MHz
4	54 MHz
...	...
510	0.424 MHz
511	0.423 MHz

There are three counters per control signal, for a total of nine counters. Each counter is programmable.

- The frame counter is decreased each time a full new frame is received, based on the EOF events from the CCDC or from receiver modules.
 - A new frame is detected in the CSI2A, CSI1/CCP2B, CSI2C receivers on detection of a frame-start code (FSC) followed by a frame-end code (FEC).
 - A new frame is detected in the CCDC module by using the falling edge of the vertical synchronization signal at the input of the CCDC module.

NOTE: The rising edge of the vertical synchronization signal and the vertical synchronization polarity settings inside the CCDC cannot be used. The modules have no effect on this detection.

- The frame counter determines how many whole frames must be ignored before the delay counter is triggered. The frame counters can be set to 0 to bypass them.
- The delay counter determines the control-signal activation delay. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the control signal is asserted. If the delay counter is set to 0, the control signal is asserted immediately.
- The activation-length counter determines the control-signal assertion length. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the control-signal enable bit is disabled. If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled.

The polarity of the following signals can be individually selected:

- [TCTRL_CTRL](#) [26] STRBPSTRBPOL for the prestrobe and strobe signals
- [TCTRL_CTRL](#) [24] SHUTPOL for the shutter signal
- [TCTRL_CTRL](#) [30] GRESETPOL for the cam_global_reset signal

The software can trigger the generation of the cam_global_reset signal to the camera module. The

signal-activation length is programmable. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the global reset enable bit is disabled ([TCTRL_CTRL \[29\] GRESETEN](#) bit). If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled. The polarity of the cam_global_reset signal can be selected ([TCTRL_CTRL \[30\] GRESETPOL](#) bit).

[Figure 6-77](#) shows the use of the cam_global_reset signal set as an input or output signal. cam_global_reset is asynchronous, edge-sensitive, and asserted for at least one interconnect clock cycle

Figure 6-77. Camera ISP Timing Control Use of cam_global_reset With Global Reset Release Camera Modules

camisp-034

There are two types of shutter mechanisms: mechanical and electronic. A mechanical shutter is used only for high-resolution sensors. The three control signals (cam_global_reset, cam_shutter, and cam_strobe) are useful with a mechanical shutter. High frame rates can be achieved only with an electronic shutter. When an electronic shutter is used, none of the three control signals is used.

Mechanical shutter mechanism:

- Reset: All pixels of the sensor are reset to their black value. When the sensor has a global reset feature, the mechanical shutter can be open during reset.
- Integration: The light received by the sensor is transformed into electrical charges that are stored inside pixels. At the end of the integration time, the shutter must be closed. Exposure time is defined by the time between reset release and shutter close.
- Readout: The charges accumulated in pixels are converted to digital values that are sent to the camera receiver.

Electronic rolling shutter mechanism (ERS):

- Each line of the sensor is reset separately and read after a fixed amount of time. Expose time is defined by the time between reset and read.

6.4.5 Camera ISP Bridge-Lane Shifter

The bridge-lane shifter module contains a data-lane shifter and an optional bridge:

- The data-lane shifter routes data sent to physical pins to the proper inputs of the CCDC module. It is controlled by the [ISP_CTRL \[7:6\]](#) SHIFT register. [Table 6-35](#) describes the different configurations.

Table 6-35. Camera ISP Bridge-Lane Shifter

Sensor	Connected to	Data Lane Shifter 0	Data Lane Shifter 1	Data Lane Shifter 2	Data Lane Shifter 3	Note
8 bits	[7:0]	8 bits	6 bits	4 bits	2 bits	
	[9:2]	10 bits	8 bits	6 bits	4 bits	
	[11:4]	12 bits	10 bits	8 bits	6 bits	
	[13:6]	14 bits	12 bits	10 bits	8 bits	CSI2 only
10 bits	[9:0]	10 bits	8 bits	6 bits	4 bits	
	[11:2]	12 bits	10 bits	8 bits	6 bits	
	[13:4]	14 bits	12 bits	10 bits	8 bits	CSI2 only
12 bits	[11:0]	12 bits	10 bits	8 bits	6 bits	
	[13:2]	14 bits	12 bits	10 bits	8 bits	CSI2 only
14 bits	[13:0]	14 bits	12 bits	10 bits	8 bits	CSI2 only

Blue shading means that the data is too wide for the Video processing hardware: use IVA2.2.

Green shading means that precision is increased for intermediate results.

Orange shading means that precision is reduced.

Unshaded cells imply normal precision.

- An optional bridge allows the packing of bytes into 16-bit words. When it is used, the maximum data rate allowed is increased. The placement of 8-bit data inside 16-bit words is configurable through the [ISP_CTRL \[3:2\]](#) PAR_BRIDGE register. This mode can be useful to transfer an YCbCr data stream or compressed stream to memory at very high speed:
 - A minimum line-blanking period of 2 pixels must be obeyed when the bridge is enabled.
 - Some CCDC modules cannot work with the bridge. For details, see [Figure 6-79](#).

6.4.6 Camera ISP Video-Processing Front End

The video-processing front end (VPFE) comprises the CCDC and the lens-shading compensation.

6.4.6.1 Camera ISP CCDC

6.4.6.1.1 Camera ISP CCDC Features

The CCDC is responsible for accepting RAW (unprocessed) image/video data from a sensor. It can also accept YUV video data in numerous formats. For RAW inputs, the CCDC output requires additional image processing to transform the input image to a final processed image. This processing can be performed either on-the-fly in the preview engine, or in software on the IVA2.2 subsystem. In parallel, RAW data input to the CCDC can be used for computing statistics (H3A, histogram) to eventually control image/video tuning parameters. The CCDC module supports the following features:

- **Image sensors:** Supports most image sensors (resolutions up to 4096 x 4096).
- **CCDC interface:** The camera ISP module interface comes either from the external parallel interface or from the output of the CSI2A, CSI2C, CSI1/CCP2B receivers (through the video-port interface). It is a 16-bit interface. To raise this maximum 16-bit interface, the bridge data-lane shifter before the CCDC module allows the packing of 8-bit data into 16 bits (not supported with ITU mode):
 - Supports two synchronization modes:
 - **SYNC mode:** In this mode, the cam_hs and cam_vs signals use dedicated wires. Synchronization signals are provided by either the sensor or the camera ISP. This mode works with 8-, 10-, 11-, 12-, and 14-bit data. It supports both progressive and interlaced image-sensor modules.

NOTE: Input from CSI1/CCP2B is limited to 12 bits, and input from CSI2 is limited to 14 bits.

- **ITU mode:** In this mode, the image-sensor module provides an ITU-R BT 656-compatible data stream. Horizontal and vertical synchronization signals are not provided to the interface. Instead, the data stream embeds SAV and EAV synchronization code. This mode works in 8- and 10-bit configurations.
- **RAW data processing:** Output data can go directly to memory for software processing, or to the PREVIEW module for further processing. The operations include:
 - Optical clamp
 - Black-level compensation
 - Faulty-pixel correction
 - 2D map based lens-shading compensation (LSC)
 - Data formatter and video port
 - Output formatter and Culling
 - DC subtract
- **YUV data processing:** The output data can go directly to memory for software processing or to the Resizer module for further processing. The operations include:
 - Output formatter and Culling
 - DC subtract
- **Memory ports:** The CCDC module can access memory as a master through the CRSBL, so it does not require the assistance of the system DMA.

6.4.6.1.2 Camera ISP CCDC Block Diagram

Figure 6-78 shows the top-level block diagram of the CCDC module.

Figure 6-78. Camera ISP CCDC Block Diagram

The data flow through the module differs, depending on whether the input is RAW data or YUV data. It also depends on the application scenario. See [Table 6-21](#) for ISP and CCDC allowed data flows.

For RAW8/10 data ([CCDC_SYN_MODE](#) [13:12] INPMODE = 0 [CCDC_REC656IF](#) [0] REC656ON = 0), the following functions apply:

- Video-preview and video-capture data flows can pass through the optical-clamp, black-level compensation, faulty-pixel correction, lens-shading compensator, and data-reformatter submodules. Output is transmitted to the computing statistics (H3A, histogram) modules for further processing.
- JPEG still image capture data is not processed by the internal CCDC modules. The data flow is sent to memory through the SBL, Circular buffer, and MMU to be read by the external JPEG CODEC.
- RAW still-image-capture data flow typically passes through the optical clamp, black-level compensation, faulty-pixel correction, lens-shading compensator and output-formatter submodules.

For YUV data ([CCDC_SYN_MODE](#) [13:12] INPMODE = 1 or 2 [CCDC_REC656IF](#) [0] REC656ON = 1), the following functions apply:

- Data can be written to memory directly through the central-resource SBL module or sent to the Resizer module for upscaling or downscaling.

For JPEG data coming from the camera parallel interface (CPI), the following settings apply for proper CCDC configuration:

- [ISP_CTRL](#)[29] CCDC_WEN_POL = Depending on the JPEG sensor
- [CCDC_SYN_MODE](#)[5] EXWEN = 1
- [CCDC_SYN_MODE](#)[13:12] INPMOD = 0
- [CCDC_SYN_MODE](#)[11] PACK8 = 1
- [CCDC_SYN_MODE](#)[10:8] DATSIZ = 7

- [CCDC_CFG\[8\]](#) WENLOG = 1
- [CCDC_VERT_LINES\[14:0\]](#) NLV = 0
- [CCDC_HSIZE_OFF\[15:0\]](#) LNOFST = 0

6.4.6.1.3 Camera ISP CCDC Functional Operations

6.4.6.1.3.1 Camera ISP CCDC SYNC CTRL Module

The SYNC CTRL module receives the pixel-clock signal from the image sensor (PCLK). The module can be slave or master of the horizontal and vertical synchronization signals (HS and VS) and of the field-identification signal (FIELD).

The HS, VS, and FLD signals can be set as inputs or outputs. The polarity of the HS, VS, and FLD signals can be set as positive or negative. If the HS, VS, and FLD signals are output, the signal length can be set.

6.4.6.1.3.2 Camera ISP CCDC Input Sampling and Formatting

- Data is latched by the pixel clock.
- Pixel-clock polarity can be either rising- or falling-edge. This is set through [ISP_CTRL \[4\]](#) PAR_CLK_POL.
- Data can be interpreted as normal or inverted ([CCDC_SYN_MODE\[6\]](#) DATAPOL).
- For RAW data:
 - Data is clipped to the number of LSBs specified in the [CCDC_SYN_MODE](#) [10:8] DATSIZ field. This also sets the maximum data size allowed in subsequent clipping/limiting operations and is the output data alignment if data is written to memory.
- For YUV data (BT656 or SYNC mode):
 - The MSB of the chroma signal can also be inverted ([CCDC_CFG](#) [13] MSBINVI). It adds 128 to chrominance signals, to be compatible with several sensors.
- BT656 decoder: Separates data and synchronization signals. This module outputs HS, VS, and FIELD signals.

6.4.6.1.3.3 Camera ISP CCDC Initial Processing

Optical Clamp

The optical black clamping function provides a means of averaging the optically black pixels and subtracting that value from each input pixel as a first step. The goal is to remove an offset caused by the sensor technology.

The averaging circuit takes an average of masked (black) pixel values from the image sensor, averaging pixels at the start ([CCDC_CLAMP](#) [24:10] OBST) of each line ([CCDC_CLAMP](#) [30:28] OBSLEN) and for the number of indicated lines ([CCDC_CLAMP](#) [27:25] OBSLN), plus an optional gain adjustment ([CCDC_CLAMP](#) [4:0] OBGAIN), and subtracting this value from the image data at the succeeding line. Users can control the position of the black pixels, the number of pixels (1, 2, 4, 8, or 16) in each line averaged, and the averaged number of lines (1, 2, 4, 8, or 16).

Alternately, users can disable black clamp averaging ([CCDC_CLAMP](#) [31] CLAMPEN) and select a constant black value for subtraction ([CCDC_DCSUB](#) [13:0] DCSUB), instead of using the calculated average value.

NOTE: For YUV data, this operation subtracts a fixed value ([CCDC_DCSUB](#) [13:0] DCSUB) from the luminance sample. To disable this operation, set the subtraction value to zero. This function does not clip negative results to 0 for YUV 8 bit input or REC656 input modes ([CCDC_SYN_MODE](#) [13:12] INPMOD == 2 || [CCDC_REC656IF](#) [0] REC656ON == 1).

This function does not clip negative results to 0 for YUV 8 bit input or REC656 input modes ([CCDC_SYN_MODE](#) [13:12] INPMOD == 2 || [CCDC_REC656IF](#) [0] REC656ON == 1).

Figure 6-79 shows an optical clamp representation.

Figure 6-79. Camera ISP CCDC Optical Clamp Representation

Black-Level Compensation

After the optical clamp, black-level compensation is applied to the data. In this operation, a fixed value, depending on the color (R/Ye, Gr/Cy, Gb/G, and B/Mg), can be subtracted from the data. The offset ([CCDC_BLKCMP](#) register, fields R_YE, GR_CY, GB_G, B_MG) applied to each data sample is selected according to the pixel position (0/1/2/3) and the color (0/1/2/3) specified for each pixel position ([CCDC_COLPTN](#)). The color pattern definition is flexible to accommodate different sensor types (such as Bayer CFA sampling, VGA Movie Mode).

Faulty-Pixel Correction

Faulty-pixel correction in the CCDC module requires the camera driver to have information about the image-sensor faulty-pixel number and positions. This method leads to the best image quality. However, if the position of the faulty pixels is unavailable to the camera driver, it can apply another faulty-pixel correction algorithm in the preview module. This algorithm leads to lower-quality images.

The CCDC module implements an optional ([CCDC_FPC](#) [15] FPCEN) faulty-pixel correction operation using a look-up table stored in external memory, which contains information about the horizontal and vertical positions of the pixels to be corrected, as well as the type of operation to be performed on the pixels. The [CCDC_FPC_ADDR](#) register specifies the starting address in memory for the faulty-pixel correction table.

NOTE: The memory address must be 64-byte-aligned (6 LSBs are ignored).

NOTE: For YUV data, the faulty-pixel correction operation is not applicable and must be disabled/bypassed ([CCDC_FPC](#) [15] FPCEN).

6.4.6.1.3.4 Camera ISP CCDC Data Formatter, Lens-Shading Compensation, and Video-Port Interface

NOTE: For YUV data, the data formatter, lens-shading compensation, and video-port interface must be bypassed ([CCDC_FMTCFG](#) [15] VPEN = 0x0 and [CCDC_SYN_MODE](#) [18] VP2SDR = 0x0).

The data-formatter module can be enabled to rearrange data after the faulty-pixel correction operation. It is intended to be used:

- When output data lines from the CCDC include pixels from multiple resolution lines. Internally, these sensors combine pixels from multiple horizontal lines into one output pseudoline.
- To smooth bandwidth. This helps reduce peak bandwidth when image cropping is used with the Resizer.

The reformatter module performs the decomposition before the remainder of the normal CCDC processing stages.

The lens-shading compensation (LSC) module can be placed at two different locations:

- Before the data reformatter. It can only be used for Bayer sensors. The H3A video port gets the shading corrected image.
- After the data reformatter. This setup is required for non-Bayer sensors. Histogram and preview modules get the shading corrected image; however, H3A receives a non-corrected image.

Video-port/data-formatter output can also be saved to memory (instead of the RAW data). When [CCDC_SYN_MODE](#) [18] VP2SDR is set to 1, video-port data is sent to the output formatter. In addition, the [CCDC_SYN_MODE](#) [17] WEN bit must be enabled to store the output to memory.

The data-formatter and video-port interfaces are only 10 bits wide; therefore, the input data must be adjusted as it enters these modules. For flexibility, the bits to be retained can be selected by [CCDC_FMTCFG](#) [14:12] VPIN.

The reformatter decomposes each input line into multiple output lines with new, internally generated HS/VS signals. The reformatter sends it to memory or to other camera ISP modules. These new HS/VS signals, rather than the original sensor HS/VS signals, then gate the downstream processing.

Conversion Area Select Parameters

When the data formatter is enabled, HS/VS signals are still generated as output ([CCDC_SYN_MODE](#) [16] VDHDEN = 0x1). The settings for these output signals are in the following fields:

- [CCDC_HD_VD_WID](#)[27:16] HDW
- [CCDC_HD_VD_WID](#)[11:0] VDW
- [CCDC_PIX_LINES](#)[31:16] PPLN
- [CCDC_PIX_LINES](#)[15:0] HLPRF

NOTE: These four registers are not used when HS/VS signals are input signals ([CCDC_SYN_MODE](#) [16] VDHDEN = 0x0).

NOTE: The settings reflect those for the sensor readout frame, not the resultant reformatted frame.

Registers [CCDC_FMT_HORZ](#) and [CCDC_FMT_VERT](#) affect the input framing even if data formatter is disabled.

Registers [CCDC_HORZ_INFO](#), [CCDC_VERT_START](#), and [CCDC_VERT_LINES](#) control the output formatter framing. It is used only when the CCDC output is sent to memory.

Figure 6-80 shows the data formatter conversion area selection.

Figure 6-80. Camera ISP CCDC Data Formatter Conversion Area Selection

Line Decomposition

When enabled, the reformatter can be configured to operate in line-alternating mode or program mode ([CCDC_FMTCFG \[1\] LNALT](#)).

When line-alternating mode is enabled, the reformatter swaps even and odd lines. Basically, the 0th input line is output as the first line, the first input line is output as the 0th line, and so on. If this option is set, the start and number of lines for the formatter ([CCDC_VERT_START](#) and [CCDC_VERT_LINES](#)) must be even.

In program mode, or normal reformatter mode, the goal is to convert a single line of movie mode data to 1, 2, 3, or 4 lines of Bayer data. Each incoming line is decomposed according to the data-formatter settings and buffered into an internal line memory. The readout of the resultant multiple reformatted lines occurs as the next input line is being read from the sensor (and reformatted) to ensure that all output lines are fully constructed. The reformatter is subject to the restrictions listed in [Table 6-36](#).

Table 6-36. Camera ISP CCDC Reformatter Output Limitations

Number of Output Lines/Input Line	Max Pixels/Output Line
1	4 * 1376
2	2 * 1376
3	1 * 1376
4	1 * 1376

The reformatter derives its flexibility from supporting up to 8 different addresses and a program that can contain up to 16 entries each for the odd and even lines. Each of the 8 addresses supports either auto increment or auto decrement. This capability is the key for supporting a multitude of readout patterns. The following examples show the programmability of the reformatter. Decomposition is controlled by defining the following parameters:

- [CCDC_FMTCFG \[3:2\] LNUM](#)
Number of lines into which each input line is to be decomposed
- [CCDC_FMTCFG \[11:8\] PLEN_EVEN](#)
Number of program entries on even line
- [CCDC_FMTCFG \[7:4\] PLEN_ODD](#)
Number of program entries on odd line
- CCDC_FMT_ADDRx (x = 0:7)
Output line in which the original pixel is to be placed, and initial address on the output line
- [CCDC_PRGEVEN0](#) or [CCDC_PRGEVEN1](#)
Program to be run on the even input lines
- [CCDC_PRGODD0](#) or [CCDC_PRGODD1](#)
Program to be run on the odd input lines

The CCDC_FMT_ADDRx registers define 8 address pointers (ADDR0 to ADDR7) that define which output line the input pixel belongs to, and the starting address (position) on that output line. Users can use up to 8 address pointers. The address pointer can be incremented or decremented, depending on the input pixel pattern. The address value computed should always follow the reformatter rules as formerly stated and should never be negative.

Lens-Shading Compensation

- Overview

The purpose of the LSC function is lens-shading correction by multiplying an image with a gain factor 2-D map, pixel by pixel. The image must be in Bayer CFA format having a 2x2 color pattern. The gain factor map is stored in external memory downsampled, and is accessed and upsampled by the LSC module before being applied to the pixel data.

The LSC function is useful for lens-shading compensation and for scene- and image-dependent lighting adjustment. Downsampled gain map reduces memory requirements for storage and bandwidth requirements for access of the gain maps in external memory.

- Features supported

- The memory stored gain map is MxN downsampled, M being the horizontal sampling factor, N being the vertical sampling factor, M and N being {4, 8, 16, 32, 64} independently and N \leq M
- 8-bit entries in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with optional base of 1.0)
- Up to 10-bit unsigned image data input/output
- Up to 4096 x 3072 image dimension

- Functional description

The lens-shading correction module multiplies an image by a gain map that is stored downsampled in memory. The gain map can be dependent on aperture, lens-shading characteristics, and other photographic settings. It is generally used to correct the dim corner effect, but can also be used to implement adaptive lighting adjustment.

Separate horizontal and vertical sampling factors allow the lens-shading correction to work with the normal 1:1 aspect ratio image pixels, as well as tall-and-skinny pixels typical in the sensors preview mode image data.

6.4.6.1.3.5 Output Formatter

The output formatter starts with a framing selection to limit the processing area by setting [CCDC_HORZ_INFO](#), [CCDC_VERT_START](#), and [CCDC_VERT_LINES](#) registers. This framing selection is applied in addition to the framing applied at the beginning and at the end of the data formatter operation if the video-port path to memory is selected ([CCDC_SYN_MODE](#) [18] VP2SDR).

The option to send the CCDC output to the Resizer module ([CCDC_SYN_MODE](#) [19] SDR2RSZ) should not be used when in RAW data mode, because the Resizer operates only on YUV format data. Use the preview module when resizing is desired in RAW data mode.

Low-Pass Filter (LPF)

An optional horizontal low-pass antialiasing filter can be applied ([CCDC_SYN_MODE](#) [14] LPF) after reframing. The low-pass filter consists of a simple 3-tap (1/4, /12, and 1/4) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled. Use of the LPF is intended for bandwidth reduction if culling is enabled.

NOTE: For YUV data, the LPF must be disabled ([CCDC_SYN_MODE](#) [14] LPF = 0x0).

Culling

An optional culling operation can be enabled ([CCDC_CULLING](#) register). This operation allows selected pixel data to be culled (deleted) from a line ([CCDC_CULLING](#) [31:24] CULHEVN, [CCDC_CULLING](#) [23:16] CULHODD – 8-bit repeating mask, one per field) and selected lines to be culled from a frame ([CCDC_CULLING](#) [7:0] CULV).

[Figure 6-81](#) is an example of how register values apply the decimation pattern to the data. The red pixels are saved to memory and the white pixels are discarded. In this example, [CCDC_CULLING](#) = 0x239A0066:

- [CCDC_CULLING](#) [31:24] CULHEVN = 0x23
- [CCDC_CULLING](#) [23:16] CULHODD = 0x9A
- [CCDC_CULLING](#) [7:0] CULV = 0x66

NOTE: Culling can be used with YUV data, but care must be taken to preserve the YUV422 output format.

Figure 6-81. Camera ISP CCDC/Culling: Example for Decimation Pattern

A-Law Compression

An optional 10-to-8-bit A-Law compression using a fixed A-Law table can be applied ([CCDC_ALAW](#) [3] CCDTBL) as the final processing stage. Using this causes data width to be reduced to 8 bits and allows packing to 8 bits/pixel when saving to memory. Because data resolution can be greater than 10 bits at this stage, the 10 bits for input to the A-Law operation must be selected ([CCDC_ALAW](#) [2:0] GWDI).

The preview module has an inverse A-Law table (A-Law decompression) option so that this nonlinear operation can be reversed if this saved data is to be read back in for further processing.

NOTE: A-Law compression must not be used ([CCDC_ALAW](#) [3] CCDTBL = 0) with YUV data.

Figure 6-82 show the A-Law table.

Figure 6-82. Camera ISP CCDC A-Law Table

Line-Output Control

NOTE: Line-output control can be used with YUV data.

The CCDC final stage is line-output control, which controls how the input sensor lines are written to memory. The value of **CCDC_SDR_ADDR** [31:0] ADDR defines the starting address where the frame should be written in memory. The value of **CCDC_HSIZE_OFF** [15:0] LNOFST defines the distance between two lines for each output line to memory. The starting address and line-offset values should be aligned to 32-byte boundaries; that is, either 16 or 32 pixels, depending on the **CCDC_SYN_MODE** [11] PACK8 setting. Register **CCDC_SDOFST** can be used to define additional offsets, depending on the field ID and even/odd line numbers. This provides a means to deinterlace an interlaced 2-field input and to invert an input image vertically. See [Table 6-37](#).

Table 6-37. Camera ISP CCDC CCDC_SDOFST Description

Register	Description
CCDC_SDOFST [14] FIINV	Invert interpretation of the field ID signal
CCDC_SDOFST [13:12] FOFST	Offset, in lines, of field = 1
CCDC_SDOFST [11:9] LOFTS0	Offset, in lines, between even lines on even fields (field 0)
CCDC_SDOFST [8:6] LOFTS1	Offset, in lines, between odd lines on even fields (field 0)
CCDC_SDOFST [5:3] LOFTS2	Offset, in lines, between even lines on odd fields (field 1)
CCDC_SDOFST [2:0] LOFTS3	Offset, in lines, between odd lines on odd fields (field 1)

Line Output Control: 2D Addressing Example

The CCDC memory port can be configured to write a subimage into a bigger image buffer. This feature is useful for overlaying a video preview flow with the rest of the display. To use this feature, the **CCDC_SDR_ADDR** [31:0] ADDR register points to the first pixel to write and the **CCDC_SDOFST** [13:12] FOFST is set to the size of one line of the destination buffer.

NOTE:

- This mode can be used only when the source and destination buffers use the same image format.
 - 2D addressing is also supported by other camera ISP modules.
-

Line-Output Control: Examples

Figure 6-83 shows an example of sample formats of input and output images.

Figure 6-83. Camera ISP CCDC/Line-Output Control: Sample Formats of Input and Output Images

CCDC_SDOFST[14] FIINV = 0x0	;Non inverse
CCDC_SDOFST[13:12] FOFST = 0x0	;+1 line; first line, even field
CCDC_SDOFST[11:9] LOFST0 = 0x1	;+2 lines; even lines, even fields
CCDC_SDOFST[8:6] LOFST1 = 0x1	;+2 lines; odd lines, even fields
CCDC_SDOFST[5:3] LOFST2 = 0x1	;+2 lines; even lines, odd fields
CCDC_SDOFST[2:0] LOFST3 = 0x1	;+2 lines; odd lines, odd fields

CCDC_SDOFST[14] FIINV = 0x1	;inverse
CCDC_SDOFST[13:12] FOFST = 0x0	;+1 line; first line, even field
CCDC_SDOFST[11:9] LOFST0 = 0x5	;−2 lines; even lines, even fields
CCDC_SDOFST[8:6] LOFST1 = 0x5	;−2 lines; odd lines, even fields
CCDC_SDOFST[5:3] LOFST2 = 0x5	;−2 lines; even lines, odd fields
CCDC_SDOFST[2:0] LOFST3 = 0x5	;−2 lines; odd lines, odd fields

camisp-051

Output Format

The data bits comprising each pixel are stored in the lower bits of a 16-bit memory word and the unused bits are zero-filled. The memory data format is shown in [Table 6-38](#). The format is determined by the [CCDC_SYN_MODE](#) [10:8] DATSIZ field.

If 8-bit data is input, or if A-Law compression is applied, the data can be packed through the [CCDC_SYN_MODE](#) [11] PACK8 setting so that a pixel occupies only 8 bits.

Data is output to memory only when enabled through the [CCDC_SYN_MODE](#) [17] WEN setting. The pixels are ordered in little-endian format.

Table 6-38. Camera ISP CCDC Memory Output Format for RAW Data

	Upper word		LSB(16)	Lower word		LSB(0)
	MSB(31)		MSB(15)			
16 bit	Pixel 1			Pixel 0		
15 bit	0	Pixel 1		0	Pixel 0	
14 bit	0	Pixel 1		0	Pixel 0	
13 bit	0	Pixel 1		0	Pixel 0	
12 bit	0	Pixel 1		0	Pixel 0	
11 bit	0	Pixel 1		0	Pixel 0	
10 bit	0	Pixel 1		0	Pixel 0	
9 bit	0	Pixel 1		0	Pixel 0	
8 bit	0	Pixel 1		0	Pixel 0	
8-bit packed	Pixel 3	Pixel 2		Pixel 1	Pixel 0	

NOTE: YUV data is stored in memory in packed YUV422 mode, using two pixels per 32 bits, as shown in [Table 6-39](#).

Table 6-39. Camera ISP CCDC Memory Output Format for YUV Data

Memory Address	Upper Word		Lower Word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr1	Y2	Cb1
N + 2	Y5	Cr2	Y4	Cb2

6.4.6.1.4 Camera ISP CCDC DMA

The CCDC module is a master. It has its own address generator and sends addresses and data to the central-resource shared-buffer logic. The central-resource shared-buffer logic arbitrates the data requests and generates the bursts to memory.

6.4.6.1.5 Camera ISP CCDC Memories

The CCDC module has one memory:

- REFORMATTER BUFFER: 3 x 1376 x 40 bits
- LSC PREFETCH BUFFER: 1536 x 32 bits

6.4.7 Camera ISP Video-Processing Back End

The video-processing back end (VPBE) comprises the preview and Resizer modules.

6.4.7.1 Camera ISP VPBE Preview Engine Features

The preview module is responsible for transforming data from a RAW image sensor into YUV422 data that is amenable to still-image encoding, video encoding, or display. It supports the following features:

- Flexible input: Module input data can come from the RAW image sensor (10 bits) or from memory (8 or 10 bits).
- Flexible input formats: Bayer RGB color filter array, complementary-color filter array, Super CCD Honeycom® sensors
- Horizontal averaging by a factor of 1, 2, 4, or 8 in the horizontal direction. The preview module can output a maximum of only 4096 pixels horizontally due to fixed memory-line sizes.
- A-Law decompression: Transforms nonlinear 8-bit data to 10-bit linear data. The CCDC module can perform A-Law compression.
- Noise reduction and faulty-pixel correction:
 - Dark-frame capture and subtraction
 - Horizontal median filter
 - Programmable noise filter: 3x3 kernel of same color pixels
 - Couplet faulty-pixel correction
- Digital gain and white balance
- Programmable CFA interpolation that operates on a 5x5 grid
- Programmable RGB-to-RGB blending matrix: 9 coefficients for the 3x3 matrix
- Programmable gamma correction: 1024 entries for each color held in local memory
- Programmable RGB-to-YUV color conversion: 9 coefficients for the 3x3 matrix
- Luminance enhancement (nonlinear), chrominance suppression and offset

6.4.7.1.1 Camera ISP VPBE Preview Block Diagram

[Figure 6-84](#) shows the preview engine block diagram.

Figure 6-84. Camera ISP VPBE Preview Engine Block Diagram

6.4.7.1.2 Camera ISP VPBE Preview Input Interface

The preview engine receives RAW image/video data from the video port interface through the CCDC or from the read buffer interface through the memory (PRV_PCR [2] SOURCE). When the source of input data is the CCDC, the input data is always 10 bits wide. When the source of input data is memory (read buffer interface), the data can be 8 or 10 bits wide. Use the PRV_PCR[4] WIDTH field to set the input data width. The 8 bits can be linear or nonlinear (A-Law compressed).

In addition, the preview engine can fetch a dark frame from memory, with each pixel 8 bits wide.

The frame-input size is configured using the PRV_HORZ_INFO and PRV_VERT_INFO registers.

If the input source is the CCDC, the input height set in the preview engine must be less than or equal to the output height of the video-port output of the CCDC. The input width must be at least 4 pixels smaller than the CCDC output width (SPH = 2; EPH = 2 pixels before the last pixel sent from the CCDC).

The input memory address (PRV_RSDR_ADDR) and line offset (PRV_RADR_OFFSET) registers should be aligned on 32-byte boundaries when the input source is set to memory. The dark-frame input address (PRV_DSDR_ADDR) and line offset (PRV_DRKF_OFFSET) should also be aligned on 32-byte boundaries when the dark-frame subtract function is enabled.

When the input source is memory, the preview engine always operates in one-shot mode. After enabling the preview engine and processing a frame, the enable bit is turned off and it is up to firmware to reenable it to process the next frame from memory.

When the input source is the CCDC, the preview engine can be configured to operate in one-shot mode or continuous mode ([PRV_PCR](#) [3] ONESHOT).

The SBL image data read port is shared between the preview and CSI1/CCP2B receiver module. When the image is read from memory, the read port must be affected to the preview receiver module by writing 0 into the [ISP_CTRL\[27\]](#) SBL_SHARED_RPORTA. Programmers must ensure that the CSI1/CCP2B module does not use this port before switching to the preview module.

6.4.7.1.3 Camera ISP VPBE Preview Input Formatter/Averager

Preview-engine output is limited to 4096 pixels per horizontal line to support 12 Mpix, due to line memory-width restrictions in the noise filter and CFA interpolation blocks. To support sensors that output more than 4096 pixels per line, an averager is incorporated to downsample by factors of 1 (no averaging), 2, 4, or 8 in the horizontal direction ([PRV_AVE](#) [1:0] COUNT). The horizontal distance between two consecutive pixels of the same color to be averaged is selectable from among 1, 2, 3, or 4 for both even ([PRV_AVE](#) [3:2] EVENDIST) and odd ([PRV_AVE](#) [5:4] ODDDIST) lines. This must be configured to match the input pattern type.

For example, a Bayer pattern has a horizontal distance of two pixels of the same color for both even and odd lines.

Valid output of the input formatter/averager is either 8 or 10 bits wide.

[Figure 6-85](#) shows the horizontal distances for different patterns.

Figure 6-85. Camera ISP VPBE Preview Horizontal Distances for Different Patterns

Bayer format with R/Gr and Gb/B in alternate lines
Horizontal distance between same colors is 2

camisp-308

6.4.7.1.4 Camera ISP VPBE Preview Dark-Frame Write

The preview engine is capable of capturing and saving a dark frame to memory instead of performing conventional processing steps ([PRV_PCR](#) [7] DRKFCAP).

This dark frame can later be subtracted from the RAW image data to eliminate the repeatable baseline noise level in the frame.

Each input pixel is written as an 8-bit value; if the input pixel value is greater than 255, it is saturated to 255. If a dark pixel is greater than 255, it is more likely to be faulty, and can be corrected by the faulty-pixel correction module in the CCDC. If properly corrected, the value must be less than 255 when it reaches the preview engine.

The [PRV_WSDR_ADDR](#) and [PRV_WADD_OFFSET](#) registers must be used to indicate the output address and line offset, respectively, of the dark-frame output in memory.

6.4.7.1.5 Camera ISP VPBE Preview Inverse A-Law

To save memory capacity and bandwidth, the CCDC includes an option to apply 10-bit to 8-bit A-Law compression and to pack the sensor data to 1 byte per pixel. To process this data correctly, the inverse A-Law block is provided to decompress the 8-bit nonlinear data back to 10-bit linear data if enabled ([PRV_PCR](#) [5] INVALAW). Even if the inverse A-Law block is not enabled, but the input is still 8 bits ([PRV_PCR](#) [4] WIDTH), the data is-left shifted by 2 to make it 10-bit data. If the input is 10 bits wide, no operation is performed on the data.

NOTE: When A-Law compression in CCDC is enabled during dark-frame write, it must be enabled when the stored dark frame is used.

6.4.7.1.6 Camera ISP VPBE Preview Dark-Frame Subtract or Shading Compensation

The preview engine can fetch a dark frame containing 8-bit values from memory (8 bits in input are converted internally to 10 bits by adding two zeros to the left) and subtracting it, pixel by pixel, from the incoming input frame ([PRV_PCR](#) [6] DRKFEN). This function removes pattern noise in the sensor. The output of the dark-frame subtract operation is 10 bits wide (U10Q0).

There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, the [PRV_PCR](#) [31] DRK_FAIL status bit is set to indicate a fail.

Instead of performing the dark-frame subtract, the preview engine can perform lens-shading compensation (if [PRV_PCR](#) [21] SCOMP_EN is set along with [PRV_PCR](#) [6] DRKFEN). In this case, the 8-bit unsigned value fetched from memory is multiplied by the incoming pixel, and the result is right-shifted by the number of bits specified by the [PRV_PCR](#) [24:22] SCOMP_SFT parameter (0-7 bits).

The SBL data read port is shared between the CCDC and preview module. The read port must be affected to the preview module by writing 0 into the [ISP_CTRL](#) [28] SBL_SHARED_RPORTB. Programmers must ensure that the CCDC module does not use this port before switching to the preview module.

6.4.7.1.7 Camera ISP VPBE Preview Horizontal Median Filter

The preview engine contains a horizontal median filter that can help reduce temperature-induced noise effects. The input and output of the horizontal median filter are 10 bits wide (U10Q0).

NOTE: Line-width reduction: If the horizontal median filter is enabled, the preview engine reduces the length of the output line of this stage by 4 pixels (2 starting pixels -left edge and 2 ending pixels -right edge). For example, if the input size is 656 × 490 pixels, the output is 652 × 490 pixels. There is no truncation of input data line if this block is disabled.

6.4.7.1.8 Camera ISP VPBE Preview Noise Filter and Faulty Pixel Correction

The noise filter and couplet defect correction (CDC) operate on the same 33 matrix of same color pixels. Both functions can be enabled separately using the [PRV_PCR](#) [27] DCOREN and [PRV_PCR](#) [9] NFEN bits.

The faulty pixel correction function replaces the central pixel (x0) with one of the neighbors (x1-x8) in the following cases:

- When it has been identified as faulty.
- When the feature is enabled.

The noise filter modifies the central pixel when it is enabled.

NOTE: Some details of these features are not available in public domain

6.4.7.1.9 Camera ISP VPBE Preview White Balance

The white-balance module has a digital gain adjuster and a white-balance adjuster. In the digital gain adjuster ([PRV_WB_DGAIN](#) [9:0] DGAIN), RAW data is multiplied by a fixed-value gain, regardless of the color of the pixel to be processed.

In the white-balance gain adjuster ([PRV_WBGAIN](#)), RAW data is multiplied by a selected gain corresponding to the color of the processed pixel.

NOTE: Some details of this feature are not available in public domain

6.4.7.1.10 Camera ISP VPBE Preview CFA Interpolation

The CFA function is responsible for providing full RGB data for each pixel. Depending on sensor type and configuration, interpolation and/or rephasing are required.

The CFA function can be enabled ([PRV_PCR](#) [10] CFAEN) and configured to different interpolation modes ([PRV_PCR](#) [14:11] CFAFMT).

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.10.1 Camera ISP VPBE Preview CFA for Bayer Modes

In Bayer modes, the CFA interpolation block is responsible for populating the missing color pixels at a given location, resulting in a 3-color RGB pixel. It does this by interpolating data from neighboring pixels of the same color.

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.10.2 Camera ISP VPBE Preview CFA Options

If the CFA interpolation block is disabled, the same input pixel is broadcast to all three output pixels.

NOTE: Image-size reduction: If CFA interpolation is enabled, the preview engine reduces the output of this stage. Two pixels/line in the left, right, top, and bottom edges are truncated in the Bayer/conventional and other modes.

If the CFA format is 2 downsampling in both horizontal and vertical directions, only 2 lines at the top and bottom of the image are truncated. The two left- and right-most pixels are processed.

6.4.7.1.11 Camera ISP VPBE Preview Black Adjustment

The CFA interpolation output is three pixels (red, blue, and green values) and this is fed as input to the black-adjustment module, which performs the following calculation for an adjustment of each color level:

$$\text{data_out} = \text{data_in} + \text{bl_offset}$$

The bl_offset values for each color are programmable in the [PRV_BLKADJOFF](#) register and coded in S8Q0 format (-128..+127). A simple one addition and clip operation are processed in this module. The output data_out [10..0] is signed.

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.12 Camera ISP VPBE Preview RGB Blending

The RGB2RGB blending module has a general 3x3 square matrix and redefines the RGB data from the CFA interpolation module, which can be used as a function of a color correction. This is programmable ([PRV_RGB_MAT1](#), [PRV_RGB_MAT2](#), [PRV_RGB_MAT3](#), [PRV_RGB_MAT4](#), [PRV_RGB_MAT5](#), [PRV_RGB_OFF1](#), [PRV_RGB_OFF2](#)) so that the color spectrum of the sensor can be adjusted to the human color spectrum. The input is signed 11 bits and the output is unsigned 10 bits. The following calculation is performed in this module:

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} MTX_RR & MTX_GR & MTX_BR \\ MTX_RG & MTX_GG & MTX_BG \\ MTX_RB & MTX_GB & MTX_BB \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} MTX_OFFR \\ MTX_OFFG \\ MTX_OFFB \end{bmatrix}$$

camisp-E094

Gains are in S12Q8 format, and offsets are in S10Q0 format.

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

camisp-E161

That leads to:

$$\begin{aligned} MTX_RR &= MTX_GG = MTX_BB = 256 \\ others &= 0 \end{aligned}$$

camisp-E162

6.4.7.1.13 Camera ISP VPBE Preview Gamma Correction

Gamma correction is performed on each of the R, G, and B pixels separately by indexing programmable gamma look-up tables. Each table has 1024 8-bit entries. The input data value is used to index into the table and the table content is the output.

The gamma table can be bypassed ([PRV_PCR \[26\] GAMMA_BYPASS](#)). In this case, the output of the gamma correction is the 8 MSB of the 10-bit input. The gamma table can be written only while the preview engine is disabled.

6.4.7.1.14 Camera ISP VPBE Preview RGB to YCbCr Conversion, Luminance Enhancement, Chrominance Suppression, Contrast and Brightness, and 4:2:2 Downsampling and Output Clipping

6.4.7.1.14.1 RGB-to-YCbCr Conversion

The RGB-to-YCbCr conversion module has a 3x3 square matrix and converts the RGB color space of the image data into the YCbCr color space. In this module, the following calculation is performed using the contents of the [PRV_CSC0](#), [PRV_CSC1](#), [PRV_CSC2](#), and [PRV_CSC_OFFSET](#) registers:

$$\begin{bmatrix} Y \\ Cb \\ Cr \end{bmatrix} = \begin{bmatrix} CSCRY & CSCGY & CSCBY \\ CSCRCB & CSCGCB & CSCBCB \\ CSCRCR & CSCGCR & CSCBCR \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} YOFST \\ OFSTCB \\ OFSTCR \end{bmatrix}$$

camisp-E095

Gains are in S10Q8 format, and offsets are in S8Q0 format for chroma and U10Q0 for luma.

NOTE: Program the following values after reset for correct color conversion:

- [PRV_CSC2 \[19:10\]](#) CSCGCR = 0x39E
 - [PRV_CSC2 \[9:0\]](#) CSCRCR = 0x080
-

6.4.7.1.14.2 Nonlinear Luminance Enhancement

Nonlinear luminance enhancement functions as an edge enhancer (crossed in the horizontal direction). It can be enabled or disabled using the [PRV_PCR \[15\] YNENHEN](#) parameter. If it is enabled, a look-up table with 127 20-bit entries must be programmed. Each entry contains a 10-bit signed offset value in the MSBs, and a 10-bit signed slope in the LSBs.

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.14.2.1 Chrominance Suppression

Occasionally, in very bright portions of an image, only one or two of the color channels are saturated, while the remaining channel(s) are not. This can lead to a false-color effect. One common example is the appearance of pink where white should be. Chrominance suppression can be used to correct this issue.

Chrominance suppression can be enabled or disabled using the [PRV_PCR \[16\]](#) SUPEN parameter.

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.14.2.2 Contrast and Brightness

The luminance component can be adjusted for contrast (scaling/multiplication) and brightness (offset/addition). Contrast is set in the [PRV_CNT_BRT \[15:8\]](#) CNT field (U8Q4 precision), and brightness is set in the [PRV_CNT_BRT \[7:0\]](#) BRT field (U8Q0 precision).

6.4.7.1.14.2.3 Downsampling and Output Clipping

The 4:2:2 conversion module converts image data to YCbCr-4:2:2 format by averaging every other Cb and Cr component in the horizontal direction. Before outputting the data, the preview engine performs clipping on the YCC components separately. The minimum and maximum threshold values for the Y and C values are specified using the [PRV_SETUP_YC](#) register. If no clipping is required, the register must be set to its reset values of 0xFF for the maximum Y and C values, and 0 for the minimum Y and C values.

6.4.7.1.15 Camera ISP VPBE Preview Write-Buffer Interface

The output of the preview engine may be passed directly to the Resizer ([PRV_PCR \[19\]](#) RSZPORT) and/or written to memory ([PRV_PCR \[20\]](#) SDRPORT).

If the output is written to memory, the write address ([PRV_WSDR_ADDR](#)) and line offset ([PRV_WADD_OFFSET](#)) must be on 32-byte boundaries. The output format of the YCC data is programmable by setting the [PRV_PCR \[18:17\]](#) YCPOS parameter.

The final width and height of the output vary depending on which processing functions are enabled. [Table 6-40](#) indicates how many edge pixels/lines are truncated by enabling certain modules in the preview engine. These values must be subtracted from the input height and width after the averager to determine the size of preview-engine output.

Table 6-40. Camera ISP VPBE Preview Image Cropping by Preview Functions

Image Cropping by Preview Functions		
Function	Pix/Line	Lines
Horizontal median filter	4	0
Noise filter	4	4
CFA (Bayer, Super CCD Honeycom or RGBE)	4	4
Color suppression OR luminance enhancement	2	0
Maximum total	14	8

NOTE: Different CFA modes are mutually exclusive.

6.4.7.2 Camera ISP VPBE Resizer

6.4.7.2.1 Camera ISP VPBE Resizer Features

The Resizer module enables image upsampling and downsampling, see [Table 6-41](#). The following features are supported:

- Flexible input sources:
 - Preview module: Enables on-the-fly processing

- Memory: Enables differed processing
- Memory: CCDC module: Enables on-the-fly processing
- Flexible input format:
 - YUV422 packed data (16 bits)
 - Color-separate data (8 bits). The data must be contiguous in memory. The input source for the data must be the memory: not available for on-the-fly processing.
 - Same output format as input
- Upsampling: Up to 4. Enables digital zoom:
 - General polyphase filter:
 - Ratio of 1 to 4: 4 taps (horizontal and vertical) and 8 phases
- Downsampling: Down to 0.25:
 - General polyphase filter:
 - Ratio of 0.25 to 0.5: 7 taps (horizontal and vertical) and 4 phases
 - Ratio of 0.5 to 1: 4 taps (horizontal and vertical) and 8 phases
- Constraints:
 - The following input width (IW) and output width (OW) constraints must be obeyed due to limited on-chip memory resources.

Table 6-41. Camera ISP VPBE Resizer Use Constraints

Resizer Use Constraints			Horizontal Resizer Ratio	
		0.25 to 0.5		0.5 to 4
		7 taps		4 taps
Vertical Resizer ratio	0.25 to 0.5	7 taps	OW=2048	OW=2048
	0.5 to 4	4 taps	OW=4096	OW=4096

- The horizontal resizer output rate must not exceed half the functional clock; Moreover, the horizontal resizer output rate must not exceed 100M pixels/s. This limitation applies only for the on-the-fly processing input source.
- Flexible resizing ratios: Independent resizing factors for the horizontal and vertical directions. The applicable ratio is 256/N, with N ranging from 64 to 1024.
- Programmable luminance enhancer
- Continuous and one-shot operation

6.4.7.2.2 Camera ISP VPBE Resizer Block Diagram

The resizer module performs either upsampling (digital zoom) or downsampling on image/video data within a range of 0.25 to 4 resizing. The input source can be sent to either the preview engine/CCDC or memory, and the output is sent to memory.

The resizer module performs horizontal resizing, then vertical resizing, independently. Between them there is an optional edge-enhancement feature. This process is shown in [Figure 6-86](#).

Figure 6-86. Camera ISP VPBE Resizer Process

camisp-063

6.4.7.2.3 Camera ISP VPBE Resizer Input and Output Interfaces

The input source can be sent to either the preview engine/CCDC or memory ([RSZ_CNT \[28\] INPSRC](#)). The input width ([RSZ_IN_SIZE \[12:0\] HORZ](#)) must be at least 32 pixels.

6.4.7.2.3.1 Camera ISP VPBE Resizer Preview Engine/CCDC Input Mode

In the preview engine/CCDC input mode, internal hardware synchronization signals define input frames. The horizontal starting byte ([RSZ_IN_START \[12:0\] HORZ_ST](#)) and vertical starting line ([RSZ_IN_START \[28:16\] VERT_ST](#)) define a starting pixel with respect to the upper-left corner of an input image (signaled through horizontal and vertical synchronization signals). The input width and height in the [RSZ_IN_SIZE](#) register specify the exact input range (relative to the starting pixel) necessary to generate an output frame of specified width/height.

NOTE: Care must be taken to ensure that the input sizes specified by the [RSZ_IN_START](#) and [RSZ_IN_SIZE](#) registers are less than or equal to the output from the preview engine or CCDC; otherwise, incorrect hardware operation may occur.

[RSZ_SDR_INADD](#) and [RSZ_SDR_INOFF](#) must be programmed to be 0x0 in this mode.

Also, the output ports of the CCDC ([CCDC_SYN_MODE \[19\] SDR2RSZ](#)) and preview engine ([PRV_PCR \[19\] RSZPORT](#)) to the resizer must be configured so that only one of them is enabled. If both are enabled, the CCDC gains control of this interface.

If input is from the CCDC, the output of the CCDC must be in YUV422 format (the resizer does not support resizing RAW data from the CCDC).

6.4.7.2.3.2 Camera ISP VPBE Resizer Memory-Input Mode

In memory-input mode, the memory address in [RSZ_SDR_INADD](#) points to the 32-byte-aligned memory address where the starting pixel resides.

The horizontal starting pixel ([RSZ_IN_START \[12:0\] HORZ_ST](#)) defines a starting pixel within that 32-byte alignment; HORZ_ST is constrained to 0...15 for the YUV 422 format, and 0...31 for the color-separated format.

The vertical starting pixel ([RSZ_IN_START \[28:16\] VERT_ST](#)) must be zero in memory-input mode. The [RSZ_SDR_INOFF](#) register specifies the address offset between rows of input data. The input width and height in the [RSZ_IN_SIZE](#) register specify the exact input range (relative to the starting pixel) necessary to generate an output frame of specified width/height.

Figure 6-87 shows the resizer in memory-input mode.

Figure 6-87. Camera ISP VPBE Resizer Resizer in Memory-Input Mode

camisp-115

6.4.7.2.3.3 Camera ISP VPBE Resizer Output Interface

In both input modes, the [RSZ_OUT_SIZE](#) register specifies output width/height, the [RSZ_SDR_OUTADD](#) register specifies output starting pixel (upper-left corner) memory address, and the [RSZ_SDR_OUTOFF](#) register specifies memory address offset between the beginning of output rows. The resizer output always goes to memory.

NOTE: [RSZ_SDR_INADD](#), [RSZ_SDR_OUTADD](#), [RSZ_SDR_INOFF](#), and [RSZ_SDR_OUTOFF](#) must be 32-byte-aligned; the lower 5 bits of the byte address are assumed to be zero.

Output-width constraints: The output width ([RSZ_OUT_SIZE](#) [11:0] HORZ) must be at least 16 pixels, and be even (so that the same number of Cb and Cr components is outputted). Due to the vertical memory size constraint, the output width ([RSZ_OUT_SIZE](#) [11:0] HORZ) cannot be greater than:

- 4096 pixels if the vertical resizing ratio is between 1/2 and 4 ([\(RSZ_CNT](#) [19:10] VRSZ + 1) = 512)
- 1650 pixels wide if the vertical resizing ratio is between 1/2 and 1/4 ([\(RSZ_CNT](#) [19:10] VRSZ + 1) 512)

6.4.7.2.4 Camera ISP VPBE Resizer Horizontal and Vertical Resizing

In the rest of this section:

- HRSZ is used for [RSZ_CNT](#) [9:0] HRSZ + 1.
- VRSZ is used for [RSZ_CNT](#) [19:10] VRSZ + 1.

The resizer module can upsample or downsample image data with independent resizing factors in the horizontal and vertical directions. The HRSZ and VRSZ parameters can range from 64 to 1024 to give a resampling range from 4 to 0.25 (256/HRSZ or 256/VRSZ).

The resizer module uses the same resampling algorithm for the horizontal and vertical directions.

The resizing/resampling algorithm uses a programmable polyphase sample rate converter (resampler). The polyphase filter coefficients are programmable so that any user-specified filter can be implemented.

[Figure 6-88](#) shows a general sample-rate converter where the resampling rate is equal to L/M.

Figure 6-88. Camera ISP VPBE Resizer Typical Sample-Rate Converter

L phases are used in a typical polyphase implementation. The resizer module, however, fixes the number of phases to 8 for a resizing range of 1/2 ~ 4 (RSZ = 64 ~ 512), or 4 for a resizing range of 1/4 ~ 1/2 (RSZ = 513 ~ 1024). In this way, the upsampling value (L) is fixed to either 8 or 4, and the downsampling value (M) is based on RSZ. To achieve a resizing ratio of 256/RSZ, the downsampling value (M) is equal to (PxRSZ)/256, where P is the number of phases. [Figure 6-89](#) shows the resizer functionality.

Figure 6-89. Camera ISP VPBE Resizer Functionality

[Figure 6-90](#) shows a model of the resolution of the noninteger downsampling ratio. The interpolated output from the filter is upsampled and replicated 256/P times before it is downsampled by the RSZ factor.

Figure 6-90. Camera ISP VPBE Resizer Approximation Scheme

This implementation means that a resizing ratio with 256/RSZ times the input size can be obtained. However, each output pixel is rounded to the nearest interpolated output of 1/P input-pixel precision. The polyphase filter coefficients are programmable so that any user-specified filter can be implemented. It is recommended that coefficient sets be chosen to implement a sample rate converter where a low-pass filter is used, with a cutoff frequency as shown in [Figure 6-91](#).

Figure 6-91. Camera ISP VPBE Resizer Cutoff Frequency for Low-Pass Filter

$$\omega_c = \min\left(\frac{\pi}{P}, \frac{\pi}{\left(\frac{P \times RSZ}{256}\right)}\right)$$

camisp-E126

If polyphase resampling is used, all upsampling factors can share the same set of coefficients. However, a different coefficient set is required when changing between 8-phase and 4-phase modes, and with different downsampling factors.

32 programmable coefficients are available for the horizontal direction (registers [RSZ_HFILT10](#) to

[RSZ_HFILT3130](#)) and another 32 programmable coefficients are available for the vertical direction (registers [RSZ_VFILT10](#) to [RSZ_VFILT3130](#)). The 32 programmable coefficients are arranged as either 4 taps and 8 phases for the resizing range of 1/2 ~ 4 (RSZ = 64 ~ 512), or 7 taps and 4 phases for a resizing range of 1/4 ~ 1/2 (RSZ = 513 ~ 1024)(RSZ is either HRSZ or VRSZ). [Table 6-42](#) shows the arrangement of the 32 filter coefficients. Each tap is arranged in S10Q8 format.

Table 6-42. Camera ISP VPBE Resizer Arrangement of the Filter Coefficients

Filter Coefficient	0.5x to ~4x		0.24x to ~0.5x	
	Phase	Tap	Phase	Tap
0	0	0	0	0
1		1		1
2		2		2
3		3		3
4	1	0	1	4
5		1		5
6		2		6
7		3		Not used
8	2	0	1	0
9		1		1
10		2		2
11		3		3
12	3	0	1	4
13		1		5
14		2		6
15		3		Not used
16	4	0	3	
17		1		
18		2		
19		3		
20	5	0	3	0
21		1		1
22		2		2
23		3		3
24	6	0	3	4
25		1		5
26		2		6
27		3		Not used
28	7	0	3	0
29		1		1
30		2		2
31		3		3

The indexing scheme of coefficients is oriented for dot-product (or inner product), rather than for impulse response. In other words, the first data point contributing to a particular output is multiplied by the coefficient associated with tap 0, and the last data point is multiplied by the coefficient associated with tap 3 or tap 6 (depending on whether it is 4-tap or 7-tap mode). The normal raster-scan order is used where the upper-left corner gets the (0, 0) coordinate. Pixel 0 is the left-most column of pixels for horizontal resizing, and the top-most row of pixels for vertical resizing. [Figure 6-92](#) shows an example of the alignment of input pixels to tap coefficients using a simple 1:1 resize case (4-tap mode). In this example, only one phase output is necessary.

[Figure 6-92](#) shows the alignment of input pixels to tap coefficients.

Figure 6-92. Camera ISP VPBE Resizer Alignment of Input Pixels to Tap Coefficients

camisp-116

Figure 6-92 also shows how the first output is computed when all taps are aligned with input pixels. To compute the last several pixels in each line/column, the filter requires more input pixels than the following equation calculates:

$$\text{input size} = \text{output size} * \text{RSZ}/256$$

In the former example, where the input size is X and the output size is Y, three extra input pixels are required to generate the correct number of output pixels:

$$X = Y * 256/256 + 3 \text{ (to account for the extra pixels required for filtering)}$$

The input size calculation depends on the starting phase and rounding issues in the algorithm. [Table 6-43](#) lists the input size calculations derived from the algorithm description in [Section 6.4.7.2.5](#). The input width and height parameters must be programmed strictly according to these equations; otherwise, incorrect hardware operation may occur.

Table 6-43. Camera ISP VPBE Resizer Input Size Calculations

	8-Phase, 4-Tap Mode	4-Phase, 7-Tap Mode
RSZ_IN_SIZE[12:0] HORZ	$(32 * \text{sph} + (\text{ow} - 1) * \text{hrs} + 16) * 8 + 7$	$(64 * \text{sph} + (\text{ow} - 1) * \text{hrs} + 32) * 8 + 7$
RSZ_IN_SIZE[28:16] VERT	$(32 * \text{spv} + (\text{oh} - 1) * \text{vrs} + 16) * 8 + 4$	$(64 * \text{spv} + (\text{oh} - 1) * \text{vrs} + 32) * 8 + 7$

Where:

sph = Start phase horizontal ([RSZ_CNT \[22:20\] HSTPH](#))

spv = Start phase vertical ([RSZ_CNT \[25:23\] VSTPH](#))

ow = Output width ([RSZ_OUT_SIZE \[11:0\] HORZ + extra](#))

oh = Output height ([RSZ_OUT_SIZE \[27:16\] VERT](#))

hrs = Horizontal resize value ([RSZ_CNT \[9:0\] HRSZ + 1](#))

vrs = Vertical resize value ([RSZ_CNT \[19:10\] VRSZ + 1](#))

extra = 0 when [RSZ_YENH \[17:16\] ALGO = 0](#) (edge enhancement disabled)

extra = 4 when [RSZ_YENH \[17:16\] ALGO != 0](#) (edge enhancement enabled)

The horizontal and vertical starting phases can be programmed in the **RSZ_CNT** [22:20] HSTPH and **RSZ_CNT** [25:23] VSTPH fields, respectively. The chrominance data can be resized using bilinear interpolation or the same algorithm as the luminance data (**RSZ_CNT** [29] CBILIN).

The following section explains how these fields are used in the algorithm.

6.4.7.2.5 Camera ISP VPBE Resizer Resampling Algorithm

The resizer module uses the same resampling algorithm for the horizontal and vertical directions. For the rest of this section, the horizontal direction is used in describing the resampling algorithm. The algorithm is described first for the 4-tap/8-phase mode, then for the 7-tap/4-phase mode.

[Section 6.4.7.2.5.1](#) and [Section 6.4.7.2.5.2](#) explain the generic algorithm without detailing the differences between color components. [Section 6.4.7.2.5.3](#) describes how interleaved chroma are processed when input is YUV422.

6.4.7.2.5.1 Camera ISP VPBE Resizer 4-Tap/8-Phase Mode

In the 4-tap/8-phase mode, the coefficients for each of the 8 phases may be set to interpolate 8 intermediate pixels between input pixels. For each output pixel calculation, a fine-input pointer with 1/256 input-pixel precision is incremented by the **RSZ_CNT** [9:0] HRSZ +1 value. A coarse-input pointer with 1/8 input-pixel precision (corresponds to one of the 8 phases) is calculated by rounding the fine-input pointer to the nearest 1/8 pixel. The output pixel is calculated by the dot product of the coefficients of the phase filter (selected by the coarse-input pointer) and the appropriate four input pixels. [Figure 6-93](#) shows a pseudo-code description of the resizer algorithm in the 4-tap/8-phase mode.

Figure 6-93. Camera ISP VPBE Resizer Pseudo-Code Description of the Resizer Algorithm in the 4-Tap/8-Phase Mode

camisp-064

- The starting input pixel location (in whole pixels) (see [Section 6.4.7.2.3, Camera ISP VPBE Resizer Input and Output Interfaces](#)) and the starting phase (in 1/8 pixel) (**RSZ_CNT** [22:20] HSTPH) are programmed through the resizer registers.
- A fine-input pointer is maintained in 1/256-pixel precision.
- A coarse-input pointer and a pixel-input pointer are computed for each output, based on the fine-input pointer.
- The coarse-input pointer is in 1/8 pixel precision. The pixel-input pointer is in whole-pixel precision.
- Initially, fine-input pointer = 256* starting input pixel + 32* starting phase - 256. The fine-input pointer defines the starting 1/8 pixel location covered by the filter waveform.
- For each output pixel:

```

Coarse-input pointer = /* Rounded to the nearest phase */
(fine-input pointer + 16) 5
Pixel-input pointer = /* Rounded up to a whole pixel, when already on an
(coarse-input pointer 3) + 1 integer pixel, go to next one to simplify coefficient
                                         organization */
Coefficient phase = /* 3 LSBs = phase */
(coarse-input pointer 7)
Output = dot product of the 4 coefficients and the 4 inputs starting with pixel-input pointer
Clip output to 8-bit unsigned for luma, 8-bit signed for chroma

```

- ```

fine-input pointer = fine-input pointer
+ (RSZ_CNT [9:0] HRSZ + 1)
/* distance between outputs = 1/resize_factor = (RSZ_CNT [9:0] HRSZ + 1) /256 = (RSZ_CNT
[9:0] HRSZ + 1) in 1/256 precision */

• Same algorithm in the horizontal and vertical directions, except with separate initial pixel/phase values
and separate RSZ values.

```

#### 6.4.7.2.5.2 Camera ISP VPBE Resizer 7-Tap/4-Phase Mode

In the 7-tap/4-phase mode, the coefficients for each of the 4 phases may be set to interpolate 4 intermediate pixels between input pixels. For each output pixel calculation, a fine-input pointer with 1/56 input-pixel precision is incremented by the RSZ\_CNT [9:0] HRSZ + 1 value. A coarse-input pointer with 1/2 input-pixel precision (corresponds to one of the 4 phases) is calculated by rounding the fine-input pointer to the nearest 1/2 pixel. The output pixel is calculated by the dot product of the coefficients of the phase filter (selected by the coarse-input pointer) and the appropriate 7 input pixels. Figure 6-94 shows a pseudo-code description of the resizer algorithm in the 7-tap/4-phase mode.

**Figure 6-94. Camera ISP VPBE Resizer Pseudo-Code Description of the Resizer Algorithm in the 7-Tap/4-Phase Mode**

camisp-065

- The starting input-pixel location (in whole pixels) (see [Section 6.4.7.2.3, Camera ISP VPBE Resizer Input and Output Interfaces](#)) and the starting phase (in 1/2 pixel) (RSZ\_CNT [22:20] HSTPH) are programmed through the resizer registers.
- A fine-input pointer is maintained in 1/256 pixel precision.
- A coarse-input pointer and a pixel-input pointer are computed for each output based on the fine-input pointer.
- The coarse-input pointer is in 1/2 pixel precision. The pixel-input pointer is in whole-pixel precision.
- Initially, fine-input pointer = 256 \* starting input pixel + 64 \* starting phase - 256. The fine-input pointer defines the starting 1/2 pixel location covered by the filter waveform.
- For each output pixel:

```

Coarse-input pointer = /* Round to the nearest phase */
(fine-input pointer + 32) 6
Pixel-input pointer = /* Round up to a whole pixel; when already on an
(coarse-input pointer 2) + 1 integer pixel, go to next one to simplify coefficient
 organization */
Coefficient phase = /* 2 LSBs = phase */
(coarse-input pointer 3)
Output = Dot product of the 7 coefficients and the 7 inputs starting with the pixel-input
pointer
Clip output to 8-bit unsigned for luma, 8-bit signed for chroma
/* It is acceptable to require the 8th coefficients to be filled with zeros by firmware so that 8
coefficients and 8 inputs, the last input being don't care value, are multiply-added */
Fine-input pointer = Fine input pointer + (RSZ_CNT [9:0] HRSZ + 1)
/* Distance between outputs = 1/resize_factor = (RSZ_CNT [9:0] HRSZ + 1)/256 =
(RSZ_CNT [9:0] HRSZ + 1) in 1/256 precision */

```

- Same algorithm in both the horizontal and vertical directions, but with separate initial pixel/phase values and separate RSZ values.

**NOTE:** The pixel-input pointer (pip) in the algorithm description, points to pixels, not bytes or shorts in the memory. The fine-input pointer (fip) points to a 1/256 resolution sub-pixel position. The coarse-input point (cip) points to a 1/8 or 1/4 resolution sub-pixel location, depending on the number of phases.

#### 6.4.7.2.5.3 Camera ISP VPBE Resizer Horizontal Resizing With Interleaved Chroma

Chroma inputs, Cb and Cr, are 8-bit unsigned values that represent 128-biased 8-bit signed values (the signed chroma are called U and V instead of Cb and Cr). During the resizing computation, the chroma values have the 128 bias subtracted to convert to the 8-bit signed format. After vertical resizing, the 128 bias is added back to convert back to 8-bit unsigned format.

Chroma components, which are 2:1 horizontally downsampled with respect to luma, have two methods of horizontal resizing processing: filtering with luma, and bilinear interpolation.

The horizontal resizing with interleaved chroma option can be selected in the [RSZ\\_CNT \[29\]](#) CBILIN field independently of the [RSZ\\_CNT \[22:20\]](#) HSTPH parameters. However, filtering with luma is intended only for downsampling, and bilinear interpolation is intended only for upsampling.

For horizontal resizing of Y/Cb/Cr in a combined filtering flow, the algorithm is modified as shown in the following algorithm descriptions:

##### Filter Chroma With Luma (4-Tap/8-Phase Mode):

```
For (i=0; i<output_width; i++) { /* output width depends of input width and resizing factors*/
 Coarse-input pointer = (fine-input pointer + 16) 5 /* Round to nearest phase */
 Pixel-input pointer = (coarse-input pointer 3) + 1 /* Round up to a whole pixel */
 Coefficient phase = pixel-input pointer 7 /* 3 LSB = phase */
 if (i 1 == 0) { /* even output pixel, generate YCbCr */
 Yout = dot product of the 4 coefficients and the 4 Y inputs starting with pixel-input pointer
 Cbout = dot product of the 4 coefficients and the 4 upsampled Cb inputs starting with
 pixel-input pointer
 Crout = dot product of the 4 coefficients and the 4 upsampled Cr inputs starting with
 pixel-input pointer
 Clip outputs to 8-bit unsigned for luma, 8-bit
 signed for chroma
 }
 Else /* odd output pixel, generate Y only */
 Yout = dot product of the 4 coefficients and the 4 Y inputs starting with pixel-input pointer
 Clip output to 8-bit unsigned
 }
 Fine-input pointer = fine-input pointer + (RSZ_CNT \[9:0\] HRSZ + 1)
}
}
```

##### Filter Chroma With Luma (7-Tap/4-Phase Mode):

```

For (i=0; ioutput_width; i++) { /* output width depends of input width and resizing factors*/
 Coarse-input pointer = (fine-input pointer + 32) 5 /* Round to nearest phase */
 Pixel-input pointer = (coarse-input pointer 2) + 1 /* Round up to a whole pixel */
 Coefficient phase = pixel-input pointer 3 /* 2 LSB = phase */

 if (i 1 == 0) { /* Even output pixel, generate YCbCr */
 Yout = dot product of the 7 coefficients and the 7 Y inputs starting with pixel-input pointer
 Cbout = dot product of the 7 coefficients and the 7 upsampled Cb inputs starting with
 pixel-input pointer
 Crout = dot product of the 7 coefficients and the 7 upsampled Cr inputs starting with
 pixel-input pointer
 Clip outputs to 8-bit unsigned for luma, 8-bit
 signed for chroma
 }

 Else /* Odd output pixel, generate Y only */
 Yout = dot product of the 7 coefficients and the 7 Y inputs starting with pixel-input pointer
 Clip output to 8-bit unsigned
 }

 Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}
}

```

---

**NOTE:** The chroma input values are internally replicated to realize 1:2 upsampling to line up with luma input values. Only required chroma outputs are computed; they correspond to even luma outputs.

---

### Bilinear Interpolation (4-Tap or 7-Tap):

For the bilinear interpolation flow of chroma horizontal resizing, the algorithm is adapted as follows. For the bilinear interpolation option, it is not necessary to replicate chroma samples.

```

For (i=0; ioutput_width; i++) {
 if (i 1 == 0) { /* even output pixel, generate YCbCr */
 Coarse-input pointer = ... /*Calculation issued from 4 taps or 7
 taps*/
 Pixel-input pointer = ... /*Calculation issued from 4 taps or 7 taps*/
 Yout = dot product of ... /*Calculation issued from 4 taps or 7
 taps*/
 C_fine_input_pointer = fine_input_pointer + 128*ntaps /* Points to center of filter
 kernel */
 Cidx = C_fine_input_pointer 9 /* Truncate to even pixel
 grid to find left value */

 Cbin[0] = Cb[Cidx]
 Cbin[1] = Cb[Cidx + 1]
 Crin[0] = Cr[Cidx]
 Crin[1] = Cr[Cidx + 1]
 frac = C_fine_input_pointer 511 /* 9-bit fraction */
 Cbout = ((512 - frac) * Cbin[0] + frac * Cbin[1] + 256) 9
 Crout = ((512 - frac) * Crin[0] + frac * Crin[1] + 256) 9
 Clip outputs to 8-bit unsigned for luma, 8-bit signed for chroma
 }
}

```

```

 Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
 }
 Else /* odd output pixel, generate Y only */
 ...
}

```

In the former algorithm, fixed-point arithmetic is used. The variable *frac* is an unsigned integer representing the fraction *f*. Thus,  $1 - f$  becomes  $512 - \text{frac}$ . After the sum of products, 256, representing 0.5 real-numbers, is added to the sum, and then the sum is right-shifted by 9 bits to get back to the integer chroma representation.

In both algorithm options, the chroma outputs computed are interleaved with luma values to generate the YCbYCr output format (or the alternate format specified in [RSZ\\_CNT](#) [26] YCPOS).

In the vertical resizing stage, the two chroma planes are processed interleaved as one separate image. Because there is no resolution issue vertically, and no horizontal dependency in vertical resizing, the vertical scheme is consistent with conventional processing, and is not analyzed here.

#### **6.4.7.2.5.4 Camera ISP VPBE Resizer Algorithm Functionality**

[Table 6-44](#) is an example of 1:2.56 (hrs = 100) horizontal resizing that illustrates the address calculation and chroma processing in 4:2:2 format (4-tap 8-phase mode). The starting pixel and phase are assumed to be zero.

**Table 6-44. Camera ISP VPBE Resizer Processing Example for 1:2:56 Horizontal Resize**

| Output                                                 | Y0      | Cb0 | Cr0 | Y1      | Y2  | Cb2 | Cr2     | Y3 | Y4  | Cb4     | Cr4 | Y5  |
|--------------------------------------------------------|---------|-----|-----|---------|-----|-----|---------|----|-----|---------|-----|-----|
| <b>fip (= hrsz)</b>                                    | -256    |     |     | -156    | -56 |     |         | 44 | 144 |         |     | 244 |
| <b>cip (= (fip+16)5)</b>                               | -8      |     |     | -5      | -2  |     |         | 1  | 5   |         |     | 8   |
| <b>pip (= (cip3) + 1)</b>                              | 0       |     |     | 0       | 0   |     |         | 1  | 1   |         |     | 2   |
| <b>coef ph (= cip 7)</b>                               | 0       |     |     | 3       | 6   |     |         | 1  | 5   |         |     | 0   |
| <b>Inputs needed (chroma filtered like luma)</b>       | Y0      | Cb0 | Cr0 | Y0      | Y0  | Cb0 | Cr0     | Y1 | Y1  | Cb0     | Cr0 | Y2  |
|                                                        | Y1      | Cb2 | Cr0 | Y1      | Y1  | Cb0 | Cr0     | Y2 | Y2  | Cb2     | Cr2 | Y3  |
|                                                        | Y2      | Cb2 | Cr2 | Y2      | Y2  | Cb2 | Cr2     | Y3 | Y3  | Cb2     | Cr2 | Y4  |
|                                                        | Y3      | Cb2 | Cr2 | Y3      | Y3  | Cb2 | Cr2     | Y4 | Y4  | Cb4     | Cr4 | Y5  |
| <b>Cfip (= fip+512)</b>                                | 256     |     |     | 488     |     |     | 720     |    |     |         |     |     |
| <b>Cidx (= Cfip 9)</b>                                 | 0       |     |     | 0       |     |     | 1       |    |     |         |     |     |
| <b>Inputs needed for chroma bilinear interpolation</b> | Cb0 Cr0 |     |     | Cb0 Cr0 |     |     | Cb2 Cr2 |    |     | Cb4 Cr4 |     |     |
|                                                        | Cb2 Cr2 |     |     | Cb2 Cr2 |     |     | Cb4 Cr4 |    |     |         |     |     |

Note the distinction between using {Cb0, Cb0, Cb2, Cb2} and {Cb0, Cb2, Cb2, Cb4} as input to the filter. The 4 filter taps are applied in order, so with the different chroma component repetition, the result is different (even when the coefficient phase is the same).

The Cidx of the chroma bilinear interpolation flow points to the chroma sample in linear array order, so Cidx = 1 means we Cb2 and Cb4 are being grabbed.

#### **6.4.7.2.6 Camera ISP VPBE Resizer Luma Edge Enhancement**

Edge enhancement can be applied to the horizontally resized luminance component before the output of the horizontal stage is sent to the line memories and the vertical stage. The [RSZ\\_YENH](#) [17:16] ALGO parameter can be set to disable edge enhancement, or to select a 3-tap or a 5-tap horizontal high-pass filter (HPF) for luminance enhancement. The edge enhancement algorithm is as follows:

If edge enhancement is selected, the two left-most and two right-most pixels in each line are not outputted to the line memories and the vertical stage. The **RSZ\_OUT\_SIZE [11:0]** HORZ register is the final output width, up to 1280 pixels when vertical 4-tap mode is used, and up to 640 pixels when vertical 7-tap mode is used. When edge enhancement is enabled, the horizontal resizer output width used to calculate the required input width must be **RSZ\_OUT\_SIZE [11:0]** HORZ + 4.

---

**NOTE:** Some details of this feature are not available in the public domain,

---

**RSZ\_YENH [7:0]** CORE is in U8Q0. **RSZ\_YENH [11:8]** SLOP is in U4Q4. **RSZ\_YENH [15:12]** GAIN is in U4Q4.

## 6.4.8 Camera ISP Statistics Collection Modules

The statistics-collection modules (SCMs) are the H3A and histogram modules that provide statistics on the incoming images to help designers of camera systems.

### 6.4.8.1 Camera ISP H3A

#### 6.4.8.1.1 Camera ISP H3A Features

The H3A module supports control loops for autofocus, auto white balance, and auto exposure by collecting metrics about the imaging/video data. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- Autofocus engine (AF):

The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a two-dimensional block of data referred to as a paxel. The AF engine supports the following features:

- Peak mode in a paxel (a paxel is defined as a two dimensional block of pixels): Accumulate the maximum focus value of each line in a paxel.
- Accumulation of the maximum focus value of each line in a paxel
- Accumulation mode
- Accumulation/sum mode (instead of peak mode): Accumulation of focus value in a paxel
- Up to 36 pexels/windows in the horizontal direction and up to 128 pexels/windows in the vertical direction
- Programmable width and height for the paxel/window
- Programmable red, green, and blue position within a 2x2 matrix
- Separate horizontal start for paxel and filtering
- Programmable vertical line increments within a paxel
- Parallel IIR filters configured in a dual-biquad configuration with individual coefficients (2 filters with 11 coefficients each)

- Auto exposure and auto white balance engine (AE/AWB)

The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the two-dimensional block of data is referred to as a window. Thus, other than having different names, pexels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF pexels and AE/AWB windows are programmable separately. AE/AWB supports the following features:

- Accumulation of clipped pixels along with all nonsaturated pixels
- Up to 36 horizontal windows/pixel and up to 128 vertical windows/pixel
- Separate vertical start coordination and height for a black row of pexels different from the remaining color pexels
- Programmable horizontal and vertical sampling points in a window

**NOTE:** Some details of this feature are not available in the public domain.

#### 6.4.8.1.2 Camera ISP H3A Autofocus Engine

The autofocus engine works by extracting each red, green, and blue pixel from the video stream and subtracting a fixed offset from the pixel value (128 when A-Law is enabled or 512 when A-Law is disabled). The offset value is then passed through two IIR filters, and the absolute values of the filter outputs are the focus values (FV). For each pixel, the pixel values and the two focus value outputs are accumulated for each color and sent to memory. The following sections describe this process in more detail.

Only RAW10 data is supported by the autofocus function. In some cases, RAW8 or RAW12 data can be converted to RAW10 using the data-lane shifter.

#### 6.4.8.1.3 Camera ISP H3A AE/AWB Engine

The AE/AWB engine starts by dividing the frames into windows and further subsampling each window into 2x2 blocks. Then, for each subsampled 2x2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2x2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

#### 6.4.8.2 Camera ISP Histogram

##### 6.4.8.2.1 Camera ISP Histogram Features

The histogram accepts RAW image/video data from either the video-port interface of the CCDC or from memory, performs a color-separate gain on each pixel (white/channel balance), and bins the pixels according to the amplitude, color, and region specified through the CCDC register settings. It can support 4 colors (Bayer), and up to 4 regions, simultaneously. [Figure 6-95](#) shows the processing of the histogram module.

The histogram module is typically used with 3A metrics by the host processor to adjust various parameters for processing image data. The following features are supported:

- Flexible input: Input data can come from the RAW image sensor (through the CCDC module) or from memory.
- Color-separate gain: A digital gain per color component can be applied before histogram computation.
- Histogram computation: The module performs pixel binning of the incoming RAW image data. Each bin collects the number of pixels with values in a range. If no saturation occurs, the sum of the values in every bin is equal to the total number of pixels in the input image. The histogram computation can occur over one frame or be accumulated over multiple frames. The computation occurs on rectangular regions. A histogram is computed for each color component in the image:
  - The RAW image data dynamic can be up to 10 bits (pixel values in the range 0 to 1023).
  - Range: Each bin covers a pixel range. Each bin can cover a maximum of 128 pixel values.
  - Programmable regions: There can be up to four regions. The region positions and horizontal and vertical sizes are programmable. When regions overlap, pixels from the overlapped area are accumulated into the highest-priority region only; region0 has the highest priority and region3 the lowest priority.
  - Programmable number of bins: There can be 32, 64, 128, or 256 bins per color and per region. The number of bins depends on the number of regions, because histogram memory size is fixed.
  - Color components: A histogram is computed for each color component in the RAW image. There are usually 4 color components in Bayer image sensors.
- Saturation: If the pixel count exceeds  $2^{20}-1$ , the pixel count is saturated.
- Memory clear: The histogram memory is cleared automatically when it is read.
- Output: The histogram result is stored in a local RAM read by a system initiator, typically the system DMA, to be written to memory.

#### 6.4.8.2.2 Camera ISP Histogram Block Diagram

**Figure 6-95. Camera ISP Histogram Process**

camisp-073

#### 6.4.8.2.3 Camera ISP Histogram Input Interface

The histogram receives RAW image/video data from the video port interface through the CCDC (which is interfaced to an external sensor) or from the read buffer interface through memory ([HIST\\_CNT \[3\] SOURCE](#)).

The input data is 10 bits wide if the source is the video-port interface. When the input source is from memory, data-bit width can range from 8 to 14 bits. If the input data is 8 bits packed (memory contains two 8-bit pixels for every 16 bits), the [HIST\\_CNT \[8\] DATSIZ](#) bit must be set. If memory contains one pixel for every 16 bits, the DATSIZ bit must be cleared.

Likewise, if memory contains one pixel for every 16 bits, the DATSIZ bit must be cleared. The input memory address ([HIST\\_RADD](#)) and line-offset ([HIST\\_RADD\\_OFF](#)) registers are used to specify the location of the input frame in memory. Both of these registers should be aligned on 32-byte boundaries.

The frame-input width and height are configured using the [HIST\\_H\\_V\\_INFO \[29:16\]](#) HSIZE and [HIST\\_H\\_V\\_INFO \[13:0\]](#) VSIZE register fields, respectively.

The histogram module supports 4-color Bayer color patterns. The [HIST\\_CNT \[6\]](#) CFA field is used to select the color pattern of the input data (Bayer).

#### 6.4.8.2.4 Camera ISP Histogram White Balance

A white-balance gain can be separately applied to each color channel by programming the fields in the [HIST\\_WB\\_GAIN](#) register. [Table 6-45](#) indicates which pixel index in the color pattern corresponds to each field in the WB\_GAIN register.

**Table 6-45. Camera ISP Histogram White Balance Field-to-Pattern Assignments**

| HIST_WB_GAIN fields | Bayer |
|---------------------|-------|
| WG00                | 0     |
| WG01                | 1     |
| WG02                | 2     |
| WG03                | 3     |

---

**NOTE:** There are four different physical locations, with one color per location for Bayer. See [Figure 6-96](#).

---

**Figure 6-96. Camera ISP Histogram Color Pattern Index**

| Bayer |   |
|-------|---|
| 0     | 1 |
| 2     | 3 |

camisp-309

Each gain constant is 8 bits wide with 5 bits of decimal precision (U8Q5).

#### 6.4.8.2.5 Camera ISP Histogram Binning

The histogram bins the input data by amplitude, color, and region (see [Figure 6-97](#)). Each bin is a counter, counting the number of pixels of a color in the range associated with the bin. The number of bins can be programmed to 32, 64, 128, or 256 bins in the **HIST\_CNT [5:4] BINS** field. However, due to limited histogram memory size (1024 words), the number of bins (times 4 colors) limits the number of regions that can be active, as shown in [Table 6-46](#).

**Table 6-46. Camera ISP Histogram Regions and Bins**

| Number of Bins | Number of Regions Allowed |
|----------------|---------------------------|
| 256            | 1                         |
| 128            | 2                         |
| 64             | 4                         |
| 32             | 4                         |

As indicated by [Table 6-46](#), up to four overlapping regions can be designated within the frame. Each region is defined by the horizontal starting (**HIST\_Rn\_HORZ [29:16]** HSTART) and ending (**HIST\_Rn\_HORZ [13:0]** HEND) pixels, and the vertical starting (**HIST\_Rn\_VERT [29:16]** VSTART) and ending (**HIST\_Rn\_VERT [13:0]** VEND) lines (where n is the region number 0...3).

---

**NOTE:** If the starting and ending pixels/lines are the same, the region size is treated as zero, and there is no binning for such a region.

---

##### 6.4.8.2.5.1 Camera ISP Histogram Region Priority

Up to four regions can be active at any time, but a pixel is binned into only one region. The priority is Region 0 Region 1 Region 2 Region 3. For example, the yellow pixel in [Figure 6-97](#) is binned only for Region 0, although it is present in all four regions.

**Figure 6-97. Camera ISP Histogram Region Priority**

#### 6.4.9 Camera ISP Central-Resource Shared Buffer Logic

The central-resource shared buffer logic (SBL) receives data read and write requests from the CCDC, preview, H3A, histogram, resizer, CSI2A, CSI2C, and CSI1/CCP2B modules. It arbitrates between requesters and constructs bursts to transfer data to and from memory.

The central-resource SBL performs the following functions:

- Interface to the CCDC module:
  - Collects output data from the CCDC in the write buffer (1 port)
  - Transfers faulty-pixel table data to the CCDC from the read buffer (2 ports)
  - Transfer lens-shading compensation to the CCDC engine from the read buffer. This port is shared with PREVIEW module dark frame subtract port.
- Interface to the CSI2A, CSI2C, and CSI1/CCP2B receivers:
  - Collects output from CSI2A in the write buffer (1 port)
  - Collects output from CSI1/CCP2B and CSI2C in the write buffer (1 port)
  - Transfer input data to the CSI1/CCP2B from the read buffer. This port is shared with the PREVIEW module input data read port.
- Interface to the preview module:
  - Collects output data from the preview engine in the write buffer (1 port)
  - Transfer input data to the PREVIEW engine from the read buffer (1 ports). This port is shared with CSI1/CCP2B data read port.
  - Transfer dark frame subtract data to the PREVIEW engine from the read buffer . This port is shared with CCDC lens-shading compensation read port.
- Interface to the H3A module:
  - Collects output data from the H3A in the write buffer (2 ports)
- Interface to the histogram module:
  - Transfers input data to the histogram from the read buffer (1 port)
- Interface to the resizer module:
  - Collects output data from the resizer in the write buffer (4 ports)
  - Transfers input data to the resizer from the read buffer (1 port)
- Requests arbitration between the different initiators. Based on fixed priorities.
- Performs throttle memory read requests for preview, resizer, and histogram to limit bandwidth in memory-to-memory operations

#### 6.4.9.1 Camera ISP Shared Buffer Logic Block Diagram

Figure 6-98 shows the central-resource SBL. It comprises WBL and RBL blocks, read and write buffers, and arbitration logic. The VBUSM data-width to the memory is 64 bits.

Figure 6-98. Camera ISP Shared Buffer Logic Block Diagram

camisp-078

NOTE: Red = Reads; Blue = Writes

**CAUTION**

Because some of the read ports are shared, software must enable the modules that will use the shared read port. For more information, see [Section 6.4.9.2.3, Camera ISP Shared Buffer Logic Read Buffer Logic \(RBL\) and Read Buffer](#).

### 6.4.9.2 Camera ISP Shared Buffer Logic Functional Operations

#### 6.4.9.2.1 Camera ISP Shared Buffer Logic Parameters

**Table 6-47** summarizes the central-resource SBL parameters. Those parameters are fixed at design time and cannot be changed by users. The functional operations of the central-resource SBL are based on a fixed data size of 256 bytes called a data unit (DU). P0 has the highest priority and P14 has the lowest priority.

**Table 6-47. Camera ISP Shared Buffer Logic Fixed Parameters**

| Port                 | Port Direction | Port Priority | Buffer Size Bytes | Description                                                                |
|----------------------|----------------|---------------|-------------------|----------------------------------------------------------------------------|
| CSI2A                | WRITE          | P3            | 1024 = 4DUs       | CSI2A output port                                                          |
| CSI1/CCP2B and CSI2C | WRITE          | P2            | 1024 = 4DUs       | CSI1/CCP2B output port or CSI2C output port                                |
| CCDC                 | WRITE          | P4            | 1024 = 4DUs       | CCDC output port                                                           |
|                      | READ           | P1            | 512 = 2DUs        | CCDC fault pixel correction input port                                     |

|                      | READ           | P0            | 1024 = 4DUs       | PREVIEW dark-frame input port<br>CCDC lens-shading compensation input port |
| RESIZER              | WRITE          | P5            | 1024 = 4DUs       | RESIZER output line 1 port                                                 |
|                      | WRITE          | P6            | 1024 = 4DUs       | RESIZER output line 2 port                                                 |
|                      | WRITE          | P7            | 1024 = 4DUs       | RESIZER output line 3 port                                                 |
|                      | WRITE          | P8            | 1024 = 4DUs       | RESIZER output line 4 port                                                 |
|                      | READ           | P12           | 1024 = 4DUs       | RESIZER input port                                                         |
| H3A                  | WRITE          | P10           | 512 = 2DUs        | H3A output - AF port                                                       |
|                      | WRITE          | P11           | 512 = 2DUs        | H3A output - AE/AWB port                                                   |
| HIST                 | READ           | P14           | 512 = 2DUs        | HIST input port                                                            |

#### 6.4.9.2.2 Camera ISP Shared Buffer Logic Write-Buffer Logic (WBL) and Write Buffer

The central-resource SBL uses multiple WBL blocks to interface between the modules' write ports and the write-buffer memory.

- One WBL is instantiated for each module write port.
- Each WBL collects the module's write port output data and transfers the data to the write-buffer memory. Arbitration occurs between the WBL blocks to access the write-buffer memory.
- Each WBL is responsible for tracking all corresponding DUs in the write-buffer memory. There can be 2 or 4 DUs in the write buffer associated with a WBL.
- A WBL generates a command to memory when:
  - The write data crosses a DU boundary. At this point, the module starts filling a new DU. Also, the WBL generates a command to transfer the previous DU to memory.
  - An end-of-frame occurs. The DU (even if not full) is transferred to memory, and a command is

issued.

- An end-of-line occurs. The DU (even if not full) is transferred to the memory, and a command is issued.

#### **6.4.9.2.3 Camera ISP Shared Buffer Logic Read Buffer Logic (RBL) and Read Buffer**

The central resource SBL uses multiple RBL blocks to interface between the modules' read ports and the read-buffer memory.

- One RBL is instantiated for each module read port.
- Each RBL is responsible for accepting input data from the read-buffer memory and for sending the input data to the read port of the corresponding module.
- Each RBL is responsible for tracking all corresponding DUs in the read-buffer memory. There can be 2 or 4 DUs in the read buffer associated with a RBL.
- Unlike the WBL, the RBL is not responsible for issuing the commands to memory; each individual module is responsible for doing this.

Two read ports are shared:

- Between the PREVIEW module dark frame and the CCDC lens-shading compensation input
- Between the PREVIEW module and the CSI1/CCP2B module data read input

They can only be used by one module at a given time because there is no arbitration mechanism. Software must enable only one of the two possible features attached to a port and to select the correct multiplexer configuration using the [ISP\\_CTRL \[27\]](#) SBL\_SHARED\_RPORTA and [ISP\\_CTRL \[28\]](#) SBL\_SHARED\_RPORTB registers.

#### **6.4.9.2.4 Camera ISP Shared Buffer Logic Arbitration**

The central-resource SBL arbitrates between module requests, based on fixed priorities. Read and write requests are arbitrated independently.

A total of 8 commands can be active at a time. When a new slot opens, the highest-priority transfer enters the command queue.

RBLs/WBLs are ensured access to the read/write buffer memories at least once every other cycle.

---

**NOTE:** The hardware uses burst. All bursts are precise; the total number of transfers in the burst is known at the start of the burst. All writes are posted.

---

#### **6.4.9.3 Camera ISP Shared Buffer Logic Memories**

The central-resource shared-buffer module has three memories:

- READ BUFFER: Shared by all modules 256 x 128 bits.
- WRITE BUFFER 0: Used only by the resizer module 256 x 128 bits.
- WRITE BUFFER 1: Shared by all modules except RESIZER 256 x 128 bits.

#### **6.4.9.4 Camera ISP Shared Buffer Logic Debug Registers**

Some registers are available for debugging data transfers between a module and external memory. The read-only debug registers are divided into two categories:

- 8 global request registers to capture information about any of the 52 module request registers at a given time. Each register provides information about one DU. The number 16 corresponds to the maximum number of outstanding requests, according to the protocol. Each global request register provides the following information:
  - Individual module register command number. For modules with 2 individual requesters, this field displays either 0 or 1. For modules with 4 individual requesters, this field displays 0, 1, 2, or 3.
  - Source or destination module

- Data-flow direction
- Valid bit
- 52 individual module request registers (read or write information). Each register provides information about one DU. The number of request registers assigned (2 or 4) depends on memory bandwidth requirements; modules with lower requirements are assigned 2 request registers, while modules with higher bandwidths are assigned 4 request registers.

**Table 6-48. Camera ISP Shared Buffer Logic Number of Request Registers**

| Port                 | RD/WR | Nb Request Registers   | Description                       |
|----------------------|-------|------------------------|-----------------------------------|
| CSI2A                | WRITE | 4 WR request registers | CSI2A output                      |
| CSI1/CCP2B and CSI2C | WRITE | 4 WR request registers | CSI1/CCP2B or CSI2C output        |
| CCDC                 | WRITE | 4 WR request registers | CCDC output                       |
|                      | READ  | 2 RD request registers | CCDC fault pixel correction input |
| PREVIEW              | WRITE | 4 WR request registers | PREVIEW output                    |
|                      | READ  | 4 RD request registers | PREVIEW input                     |
|                      | READ  | 4 RD request registers | PREVIEW dark-frame input          |
| RESIZER              | WRITE | 4 WR request registers | RESIZER output line 1             |
|                      | WRITE | 4 WR request registers | RESIZER output line 2             |
|                      | WRITE | 4 WR request registers | RESIZER output line 3             |
|                      | WRITE | 4 WR request registers | RESIZER output line 4             |
|                      | READ  | 4 RD request registers | RESIZER input port                |
| H3A                  | WRITE | 2 WR request registers | H3A output - AF port              |
|                      | WRITE | 2 WR request registers | H3A output - AE/AWB port          |
| HIST                 | READ  | 2 RD request registers | HIST input                        |

Each write-request register provides the following information:

- Current byte count: Number of bytes in the block of data for this command, up to 256 bytes
- Data ready: Block of data confirmed by the module
- Data sent: Data sent to the destination and waiting for status
- Upper 20 bits of the address

Each read-request register provides the following information:

- Valid: Read requested from the module
- Waiting for data: Command accepted from the source
- Data available: Data received from the source and can be read by the module
- Byte count requested: Up to 256 bytes
- Upper 20 bits of the address

#### 6.4.10 Camera ISP Circular Buffer

The circular buffer (CBUFF) maps a virtual space to a physical space by address translation. It does not change the data or store it locally.

---

**NOTE:** Addresses can be further translated by the MMU.

---

##### 6.4.10.1 Camera ISP Circular Buffer Feature List

The features are listed below:

- Two independent circular buffers (CBUFF0 and CBUFF1)
- Linear address space (virtual) mapped into a circular space (physical)
- Fully transparent for accesses out of the configured virtual space

- Maximum physical buffer size of 16x16M bytes:
  - Physical space is composed by 2,4,8 or 16 windows
  - Maximum allowed window size is 16M bytes
- Support for multiline write patterns
  - Used together with the resizer in upscale mode. Each buffer must contain at least ceil (vertical zoom factor) images lines
- Support of 2D addressing modes
- Memory fragmentation support for CBUFF0
- VRFB context grouping support
- Strong error detection mechanisms
- Buffer addresses are 64-bit aligned, but window fill level managing is byte accurate.
- Read and write accesses are supported.
- Bandwidth Control Feedback loop connected to the CSI1/CCP2B receiver flexible input

#### 6.4.10.2 Camera ISP Circular Buffer Interrupts

All events generated (see [Table 6-16](#) for details) by the circular buffer are merged into a single event at camera ISP level. This event can be mapped to MPU SS by enabling the [ISP IRQ0ENABLE](#) [21] CBUFF\_IRQ bit or to IVA2.2 by enabling the [ISP IRQ1ENABLE](#) [21] CBUFF\_IRQ bit.

#### 6.4.10.3 Camera ISP Circular Buffer Functional Description

The CBUFF module maps a virtual address space to a physical space called circular buffer. The CBUFF module can handle up to 2 independent circular buffers CBUFF0 and CBUFF1.

This section gives an overview of typical uses of the module.

##### 6.4.10.3.1 Camera ISP Circular Buffer Bandwidth Control Feedback Loop

The bandwidth control feedback (BCF) feature can be used in memory to memory operation when the camera ISP reads data through the CS1b receivers flexible input.

At a given time a certain number of physical buffers are available for the processor. Depending, if the circular buffer is configured in read or write mode, the processor can, respectively, write or read those physical buffers.

When the number of physical buffers to be processed by the processor increases, the number of physical buffers available to the camera ISP decreases. When the number of physical buffers available for the camera ISP becomes too low, the corresponding BCF signal is asserted. This signal can be used to stall the data read flow.

The camera ISP supports two mechanisms to reduce the processing speed in memory to memory operation:

- Add a fixed delay between memory read requests. Delays can be added:
  - At SBL level for all image data read ports (histogram, preview, CSI1/CCP2B and resizer)
  - At CSI1/CCP2B module level by slowing down the video port clock
- Stall memory reads based on the level of the circular buffer. That is the purpose of the BCF feature described in this section.

##### 6.4.10.3.1.1 Camera ISP Circular Buffer Single Slice Mode

The camera ISP writes data with an incremental addressing scheme to the virtual space. The physical buffer is smaller than the virtual space. Therefore, the physical buffer locations is read or written multiple times. See [Figure 6-99](#).

**Figure 6-99. Camera ISP Circular Buffer Single Slice Buffer (Write Mode)**

Physically, this circular buffer is typically in the SDRAM. The virtual space is defined by a start and an end address. The physical buffer is defined by a start address, a window size, and a window count. It is contiguous in memory.

Figure 6-100 shows the buffer organization for a 4-window buffer.

**Figure 6-100. Camera ISP Circular Buffer Single Slice Buffer Example (Write Mode)**

camisp-165

The CBUFF module can manage two independent circular buffers in single slice mode.

In case of memory-to-memory operation, the module using the data (that is, JPEG CODEC) written by the ISP into the circular buffer may be slower than the camera ISP. That is especially the case when the resizer is used for upscaling.

In this section, it is assumed that the data to be read by the camera ISP is a full frame completely present in physical memory. Sliced buffer capability is only used the buffer data at the output of the camera ISP. Therefore, the circular buffer is configured in write mode.

The basic idea is to stall the read data flow at CSIb flexible input level. This is done by blocking the response phase of the CSIb interconnect read master port. Blocking the response phase rather than the request phase allows data prefetch at SBL level.

When the count of full windows is greater than or equal to the value defined in the **CBUFFx\_CTRL[7:4]** BCF register, the data flow between the SBL buffer and the CSI1/CCP2B data read port is stalled. Data transfers resume when the full window count falls below the defined limit.

Stalling the data flow at this level does not prevent the SBL from fetching data until its buffers are full. Therefore, when data transfer resumes, data are available quickly at the CSI1/CCP2B read port level, and ISP processing can resume.

Due to SBL buffering, some data may be sent out to the circular buffer when the stall command is activated. Firmware must allocate enough space in the circular buffer to avoid an overflow. The amount of buffered data depends on the ISP configuration:

- The camera ISP Video processing hardware can contain up to 10 pixels that are sent to the SBL after stall control is activated.
- The SBL can store up to four DUs at the output of the PREVIEW module. Therefore, when the circular buffer is filled from the PREVIEW module there must be enough space to store the extra 1K byte of data.
- The data path between the resizer and preview module goes through the SBL and data is internally buffered. The SBL can buffer up to 4 DUs between the PREVIEW and RESIZER module. In other words, when the input of the PREVIEW module is stalled, the RESIZER receives up to 2K bytes before it stalls.
- The SBL can store up to four DUs for each of the RESIZERS write ports. The count of ports used by the resizer depends on the vertical scaling factor; it uses  $\text{ceil}(\text{vscale})$  ports. Each port writes into one image line and can buffer up to 1K byte.
- Depending on the resizing factor, the next write window may already contain up to three full video lines.

The largest amount of buffering is required when all of the following occur:

- The PREVIEW module is used.
- The RESIZER is used with a rescaling factor of 4x in the horizontal and vertical direction.
- The window size is not a multiple of the vertical up scaling factor.

#### **Example 6-1. Camera ISP Circular Buffer Example of 4x Digital Zoom Use:**

This example shows how to calculate the minimum required window count when this feature is used.

It is assumed that the camera ISP reads a VGA RAW8 image from memory, processes it in the preview, and scales it up to 5M pix (2560x1920). The circular buffer is used for temporary storage between the JPEG CODEC and the camera ISP. Each window is configured to contain 8 video lines and the stall command is issued when at least two windows of the circular buffer are full.

Because the circular buffer window size is a multiple of the vertical upscaling factor, the next write window is empty when the stall command is issued. However, up to 1K byte = 512 pixels are stored for each write port of the resizer. This data is written as a 512x4 pixel bloc to the circular buffer by the SBL. Between the PREVIEW and RESIZER up to 1kbyte = 512 pixels are stored. This data expands to a block of 512x4x4 pixels written to the circular buffer by the SBL. In other words, up to 7 lines of the circular buffer may be filled after the stall command is issued. A minimum of four windows must be allocated to avoid an overflow of the circular buffer.

**Example 6-1. Camera ISP Circular Buffer Example of 4x Digital Zoom Use: (continued)**
**Figure 6-101. Camera ISP Circular Buffer Control Feedback Loop Example**

The CODEC reads data from the circular buffer and flag windows as done. In this example, the stall command is released when the CODEC has completed processing W0 and W1. The camera ISP resumes writing into W3.

---

**NOTE:** Software can control the minimum full window count to issue the stall command using the **CBUFFx\_CTRL[7:4]** BCF register. Setting this value to 1 or 2 in this example may negatively affect the performance, because only up to two or three windows can be used.

---

#### 6.4.10.3.1.2 Camera ISP Circular Buffer Extended Slice Mode

In extended slice mode, both circular buffers managed by the CBUFF module are used together. One provides address translation for the read data flow, and the other for a write data flow.

**Figure 6-102. Camera ISP Circular Buffer Extended Slice Buffer Example**

The camera ISP prefetches data and buffers it in the SBL. The CSI1/CCP2B flexible input pre-buffers up to 1K byte of data. In other words, the stall control for the CSI1/CCP2B interconnect read master port must be triggered in advance. Otherwise, the camera ISP may prefetch invalid data.

The last moment when the CSI1/CCP2B interconnect read master port can be safely stalled is when the physical read buffer still contains 1K byte of valid data. The camera ISP may or may not then read the remaining data into its internal SBL buffer.

The minimum amount of buffered data depends on the circular buffer configuration and the used data format.

When the processor filling the read buffer has no more data to write, the BCF feature must be disabled (clear [ISP\\_CTRL \[23:22\] CBUFF0\\_BCF\\_CTRL](#) or [ISP\\_CTRL\[25:24\] CBUFF1\\_BCF\\_CTRL](#)) for the CBUFF attached to the read data flow. This allows the camera ISP to prefetch the remaining data from the buffer without stalling.

#### 6.4.10.3.1.3 Camera ISP Circular Buffer Fragmentation Support

This mode is available only for context 0 and CBUFF0. The mapped physical space does not need to be contiguous in memory.

---

**NOTE:** Software must ensure proper configuration of the CBUFF0 specific fragmentation support feature. Thus, the [CBUFFx\\_ADDRy](#) register must be configured correctly even if functionality was not initially required when data was accepted from ISP.

---

Software defines the location of each physical window using CBUFF0\_ADDR0 through CBUFF0\_ADDR15 (see [CBUFFx\\_ADDRy](#)). Figure 6-103 shows the fragmentation support.

**Figure 6-103. Camera ISP Circular Buffer Fragmentation Support**

Table 6-49 provides the physical address of physical windows 0 to 15 for fragmentation functionality.

**Table 6-49. Camera ISP Circular Buffer Fragmentation Support Physical Window Addresses**

| Physical Window | Fragmentation ON Register |
|-----------------|---------------------------|
| 0               | CBUFF0_ADDR0              |
| 1               | CBUFF0_ADDR1              |
| 2               | CBUFF0_ADDR2              |
| 3               | CBUFF0_ADDR3              |
| 4               | CBUFF0_ADDR4              |
| 5               | CBUFF0_ADDR5              |
| 6               | CBUFF0_ADDR6              |
| 7               | CBUFF0_ADDR7              |
| 8               | CBUFF0_ADDR8              |
| 9               | CBUFF0_ADDR9              |
| 10              | CBUFF0_ADDR10             |
| 11              | CBUFF0_ADDR11             |
| 12              | CBUFF0_ADDR12             |
| 13              | CBUFF0_ADDR13             |
| 14              | CBUFF0_ADDR14             |
| 15              | CBUFF0_ADDR15             |

#### 6.4.10.3.1.4 Camera ISP Circular Buffer VRFB Context Grouping

The VRFB is part of the SMS module and provides support for image rotation by writing the data into SDRAM and reading it back. The VRFB can rotate frames of up to 2k \* 2k pixels per context. That is sufficient to rotate the following image sizes

**Table 6-50. Camera ISP Circular Buffer VRFB Maximum Supported Frame Size**

| Frame size     | Aspect ratio |
|----------------|--------------|
| 3.1 Mega Pixel | 4/3          |
| 2.8 Mega Pixel | 3/2          |
| 2.3 Mega Pixel | 16/9         |

The CBUFF module can optionally perform address translation to group 4 contexts together. This extends the maximum frame size than can be rotated to the following:

**Table 6-51. Camera ISP Circular Buffer VRFB Extended Supported Frame Size**

| Frame size      | Aspect ratio |
|-----------------|--------------|
| 12.5 Mega Pixel | 4/3          |
| 11.1 Mega Pixel | 3/2          |
| 9.4 Mega Pixel  | 16/9         |

---

**NOTE:** VRFB context grouping is a standalone feature. It cannot be combined with circular buffering or fragmentation.

---

The VRFB supports a total of 12 contexts. The CBUFF VRFB context grouping feature groups 4 contexts together to provide a larger virtual frame buffer. CBUFF can handle up to 3 groups or 4 VRFB contexts each.

The software chooses which VRFB contexts to use by defining the base address of the 1st of the 4 contexts using the **CBUFF\_VRFB\_CTRL.BASE<sub>x</sub>** register ( $x = 0, 1, \text{ or } 2$ ). Software must ensure that translated regions do not overlap.

Software also needs to define the data width (8, 16, or 32-bits) and the orientation (0, 90, 180, or 270 degrees) using the `CBUFF_VRFB_CTRL.WIDTHx` and `CBUFF_VRFB_CTRL.ORIENTATIONx` registers.

Translation is enabled by setting the `CBUFF_VRFB_CTRL.ENABLEx` bit. Software shall not change the translation configuration or enable/disable the translation while there is active traffic from ISP interface input port in the translated region (`CBUFF_VRFB_CTRL.BASEx*256M bytes` to `CBUFF_VRFB_CTRL.BASEx+1)*256M bytes`).

Figure 6-104 shows how the "large" virtual frame buffer seen in the address map of ISP interface input port is mapped to 4 "small" virtual frames accessed through interface output port.

**Figure 6-104. Camera ISP Circular VRFB Buffer Performed Translation**

camisp-410

#### 6.4.10.3.2 Camera ISP Circular Buffer Window Management

This section explains the internal address remapping and windows management algorithm. Internally the module maintains some variables in addition to the configuration registers.

The module manages two circular buffers in parallel. Those are called CBUFF0 and CBUFF1.

**Table 6-52. Camera ISP Circular Buffer Internal Variables**

| Quantity | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CWx      | Current window index for buffer x (x = 0, 1). Possible values are 0 to allowed window count. The current value can be read using the <code>CBUFFx_STATUS[11:8]</code> CW register.                                                                                                                                                                                                                                  |
| NWx      | Next window index for buffer x (x = 0, 1). Possible values are 0 to allowed window count. The current value can be read using the <code>CBUFFx_STATUS[19:16]</code> NW register.                                                                                                                                                                                                                                    |
| CPUWx    | Window in the physical buffer that can be accessed by the CPU. Possible values are 0 to allowed window count. The current value can be read using the <code>CBUFFx_STATUS[3:0]</code> CPUW register.                                                                                                                                                                                                                |
| FCOx     | Start address, in the virtual space, of the current window. This is an internal quantity that cannot be accessed by software.                                                                                                                                                                                                                                                                                       |
| OFFSETy  | This is an internal quantity that cannot be accessed by software.<br>y = 0: Address offset used when the current window of buffer 0 is accessed<br>y = 1: Address offset used when the next window of buffer 0 is accessed<br>y = 2: Address offset used when the current window of buffer 1 is accessed<br>y = 3: Address offset used when the next window of buffer 1 is accessed                                 |
| LEVELy   | This is an internal quantity that cannot be accessed by software.<br>y = 0: Amount of data, in bytes, read or written in the current window of buffer 0<br>y = 1: Amount of data, in bytes, read or written in the next window of buffer 0<br>y = 2: Amount of data, in bytes, read or written in the current window of buffer 1<br>y = 3: Amount of data, in bytes, read or written in the next window of buffer 1 |

##### 6.4.10.3.2.1 Camera ISP Circular Buffer Startup

The status of a circular buffer (CBUFF0 or CBUFF1) is reset when it is disabled. This does not affect the configuration registers or the `CBUFF_IRQSTATUS` register. Table 6-53 shows the internal state after reset.

**Table 6-53. Camera ISP Circular Buffer Internal State After Reset**

| Quantity  | Description                  |
|-----------|------------------------------|
| CWx       | 0                            |
| NWx       | 1                            |
| CPUWx     | 0                            |
| FCOx      | <a href="#">CBUFFx_START</a> |
| OFFSET0   | 0                            |
| OFSFET1   | 0                            |
| OFFSET2,3 | 0                            |
| LEVELy    | 0                            |

#### 6.4.10.3.2.2 Camera ISP Circular Buffer Access Identification

For each access to the virtual space, the CBUFF module first checks the address (ADDR) to classify the transaction into one of the categories listed in [Table 6-54](#).

**Table 6-54. Camera ISP Circular Buffer Address Identification**

| ID | Label       | Condition                                                                                                                                                                                          |
|----|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0  | CW_CBUFF0   | <a href="#">CBUFFx_CTRL[0]</a> ENABLE = 1 and ADDR=FC00 and ADDRFC00 + <a href="#">CBUFFx_WINDOWSIZE</a> and ADDR= <a href="#">CBUFFx_END</a> (x = 0)                                              |
| 1  | NW_CBUFF0   | <a href="#">CBUFFx_CTRL[0]</a> ENABLE=1 (x = 0) and ADDR=FC00 + <a href="#">CBUFFx_WINDOWSIZE</a> and ADDRFC00 + 2* <a href="#">CBUFFx_WINDOWSIZE</a> and ADDR= <a href="#">CBUFFx_END</a> (x = 0) |
| 2  | CW_CBUFF1   | <a href="#">CBUFFx_CTRL[0]</a> ENABLE=1 and ADDR=FC01 and ADDRFC01 + <a href="#">CBUFFx_WINDOWSIZE</a> and ADDR= <a href="#">CBUFFx_END</a> (x = 1)                                                |
| 3  | NW_CBUFF1   | <a href="#">CBUFFx_CTRL[0]</a> ENABLE=1 and ADDR=FC01 + <a href="#">CBUFFx_WINDOWSIZE</a> and ADDRFC01 + 2* <a href="#">CBUFFx_WINDOWSIZE</a> and ADDR= <a href="#">CBUFFx_END</a> (x = 1)         |
| 4  | ERR_CBUFF0  | <a href="#">CBUFFx_CTRL[0]</a> ENABLE=1 and ADDR= <a href="#">CBUFFx_START</a> and ADDR= <a href="#">CBUFFx_END</a> (x = 0)                                                                        |
| 5  | ERR_CBUFF1  | <a href="#">CBUFFx_CTRL[0]</a> ENABLE=1 and ADDR= <a href="#">CBUFFx_START</a> and ADDR= <a href="#">CBUFFx_END</a> (x = 1)                                                                        |
| 6  | TRANSPARENT | Always true                                                                                                                                                                                        |

Lower IDs correspond to higher priorities in case multiple conditions are true. For example, when the current virtual window of the circular buffer 0 is accessed, at least the tests for categories CW\_CBUFF0 and ERR\_CBUFF0 are true. The final category is CW\_CBUFF0, because it has a higher priority.

Further processing depends on the category:

- TRANSPARENT: Accesses flow through the module without changing its internal state or any translation.
- ERR\_CBUFF0 and ERR\_CBUFF1: The module goes into error state for the concerned buffer (CBUFF0 or CBUFF1) and set the [CBUFF\\_IRQSTATUS\[1\]](#) IRQ\_CBUFF0\_INVALID bit (or [CBUFF\\_IRQSTATUS\[4\]](#) IRQ\_CBUFF1\_INVALID). When the module is in error state for CBUFFx, all accesses to that buffer are cancelled. In other words, any access that has an address between [CBUFFx\\_START](#) and [CBUFFx\\_END](#) (x = 0) is not transmitted to the interconnect. There are two ways to leave the error state:
  - Hardware reset
  - Disable and re-enable the buffer (CBUFF0 or CBUFF1) in error state

Accesses outside of the virtual space from the circular buffer in error state are not affected.

- CW\_CBUFF0, NW\_CBUFF0, CW\_CBUFF1 and NW\_CBUFF1: The internal state is updated and address translation is performed when the performed access type (read or write) is compatible with the current mode (read or write). Otherwise, an IRQ\_CBUFFx\_INVALID event is set and CBUFFx goes into the error state.

#### 6.4.10.3.2.3 Camera ISP Circular Buffer Address Translation

An offset is selected depending on the access category (see [Section 6.4.10.3.2.1, Camera ISP Circular Buffer Startup](#)) and the internal state of the accessed buffer. [Table 6-55](#) lists possible cases.

**Table 6-55. Camera ISP Circular Buffer Address Translation**

| Condition                                                                                                                             | Address Translation      |
|---------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| CBUFFx_CTRL[0] ENABLE=1 and ADDR= <a href="#">CBUFFx_START</a> and ADDR= <a href="#">CBUFFx_END</a> and CBUFF0 in error state (x = 0) | Access cancelled         |
| CBUFFx_CTRL[0] ENABLE=1 and ADDR= <a href="#">CBUFFx_START</a> and ADDR= <a href="#">CBUFFx_END</a> and CBUFF1 in error state (x = 1) | Access cancelled         |
| Category = CW_CBUFF0                                                                                                                  | ADDROUT = ADDRIN-OFFSET0 |
| Category = NW_CBUFF0                                                                                                                  | ADDROUT = ADDRIN-OFFSET1 |
| Category = CW_CBUFF1                                                                                                                  | ADDROUT = ADDRIN-OFFSET2 |
| Category = NW_CBUFF1                                                                                                                  | ADDROUT = ADDRIN-OFFSET3 |
| Category = ERR_CBUFF0                                                                                                                 | Access cancelled         |
| Category = ERR_CBUFF1                                                                                                                 | Access cancelled         |
| Category = TRANSPARENT                                                                                                                | ADDROUT = ADDRIN         |

#### 6.4.10.3.2.4 Camera ISP Circular Buffer Window Fill Level

Each time an access is performed into an active window (CW\_CBUFF0, NW\_CBUFF0, CW\_CBUFF1 or NW\_CBUFF1) the window level is updated. The corresponding LEVELy is incremented according to the BYTEEN input of the interconnect port. All possible BYTEEN patterns are supported. [Table 6-56](#) shows some examples. The basic idea is to count the number of ones in the BYTEEN input.

**Table 6-56. Camera ISP Circular Buffer Window Level Increment**

| BYTEEN | LEVELy Increment | Comment       |
|--------|------------------|---------------|
| 0x00   | +0               | No access     |
| 0x01   | +1               | 8 bit access  |
| 0x02   | +1               | 8 bit access  |
| 0x03   | +2               | 16 bit access |
| ...    | ...              | ...           |
| 0x07   | +3               | 24 bit access |
| ...    | ...              | ...           |
| 0x0F   | +4               | 32 bit access |
| ...    | ...              | ...           |
| 0xF0   | +4               | 32 bit access |
| ...    | ...              | ...           |
| 0xFF   | +8               | 64 bit access |

The window level is compared to `CBUFFx_THRESHOLD`. As listed in [Table 6-57](#), the following situations may occur:

**Table 6-57. Camera ISP Circular Buffer Window Level Comparison**

| Condition                                         | Description                                                                                                               |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| LEVEL0= <code>CBUFFx_THRESHOLD</code> ( $x = 0$ ) | Current window of buffer 0 full.<br>Internal window indexes, levels, and offsets are updated.                             |
| LEVEL1= <code>CBUFFx_THRESHOLD</code> ( $x = 0$ ) | Next window of buffer 0 full.<br>An <code>IRQ_CBUFF0_INVALID</code> error event is set and CBUFF0 enters the error state. |
| LEVEL2= <code>CBUFFx_THRESHOLD</code> ( $x = 1$ ) | Current window of buffer 1 full                                                                                           |
| LEVEL3= <code>CBUFFx_THRESHOLD</code> ( $x = 1$ ) | Next window of buffer 1 full.<br>An <code>IRQ_CBUFF1_INVALID</code> error event is set and CBUFF1 enters the error state. |

#### 6.4.10.3.2.5 Camera ISP Circular Buffer Window Pointer and Offset Update

When the current window of a circular buffer (`CBUFFx`,  $x = 0$  or  $1$ ) is full:

- The "next window" becomes the "current window"
  - $CWx - NW$
  - $LEVEL(2*x) - LEVEL(2*x+1)$
  - $OFFSET(2*x) - OFFSET(2*x+1)$
  - $FCOx - FCOx + CBUFFx_WINDOWSIZE$
- A new "next window" if opened. The update is done in a circular manner: the first window in the physical space is reused after the last one
  - $NW - (NW+1)$  modulo  $WC$
  - $LEVEL(2*x+1) - 0$
  - $VPA - VPA + CBUFFx_WINDOWSIZE$
  - When fragmentation used for CBUFF0:
    - $OFFSET(2*x+1) - OFFSET(2*x+1) + VPA * CBUFFx_WINDOWSIZE - CBUFF0_ADDR[CBUFF0_STATUS[WA]]$
  - When the "next window" is moved from the last buffer to the first:
    - $OFFSET(2*x+1) - OFFSET(2*x+1) + WCx * CBUFFx_WINDOWSIZE$

---

**NOTE:**  $WC$  is the window count defined by the `CBUFFx_CTRL[9:8]` `WCOUNT` register.

---

#### 6.4.10.3.3 Camera ISP Circular Buffer CPU Interaction

The CBUFF module sets an `IRQ_CBUFFx_READY` event to inform the CPU that it can access the  $CPUx$  window in the physical buffer. The CBUFF module cannot monitor CPU accesses to the physical buffer. The CPU must indicate when it has completed the processing of the  $CPUWx$  window by writing the `CBUFFx_CTRL[2]` `DONE` bit. This increments the CPU window index  $CPUWx$  by one modulo the window count.

The behavior depends on whether read or write mode has been selected using the `CBUFFx_CTRL[1]` `RWMODE` bit.

---

**NOTE:** Some details of this feature are not available in the public domain.

---

## 6.4.11 Camera ISP MMU Logic

### 6.4.11.1 Camera ISP MMU Features

The camera ISP MMU contains a translation lookaside buffer (TLB) that holds translations and properties for current pages. This TLB can be managed statically through the configuration slave port, or by the internal hardware table-walking logic (TWL), which can autonomously traverse the page table on a TLB miss. The TWL can be enabled or disabled (MMU.MMU\_CNTL [2] TWLENABLE).

On a TLB miss, the initiator is stalled until a valid address translation is found. If no valid translation is found, a translation fault interrupt is generated to the processor. It is a nonrecoverable situation, which leads to the camera ISP being reset by the processor software.

The MMU provides up to 4G bytes of virtual memory.

### 6.4.11.2 Camera ISP MMU Functional Description

For a detailed description of the MMU, see [Chapter 15, Memory Management Units](#).

---

**NOTE:** In the camera ISP MMU, the endianess feature is available for write, but conversion for read is not possible.

---

## 6.5 Camera ISP Basic Programming Model

### 6.5.1 Programming the ISP PRCM Clocks Configuration

The camera subsystem clocks are provided by the PRCM module. The software must set the PRCM registers as follows:

1. To set the cam\_mclk:

The DPLL4\_ALWON\_FCLKOUT clock is sourced by the system clock (SYS\_CLK) at a X frequency and calculated as follows:

$$\text{DPLL4\_ALWON\_FLCKOUT} = [\text{SYS\_CLK (X frequency)} \times 2 \times M (0xE1)] / [N (0x9) + 1]$$

$$\text{cam\_mclk} = \text{DPLL4\_ALWON\_FCLKOUT} / \text{CLKSEL\_CAM (4)}$$

$$\text{PRCM.CM\_CLKSEL\_CAM.CLKSEL\_CAM} = x$$

2. Enable the cam\_fclk clock:

$$\text{PRCM.CM\_FLCKEN\_CAM [0] EN\_CAM} = 0x1$$

3. Enable the cam\_iclk clock:

$$\text{PRCM.CM\_ICLKEN\_CAM [0] EN\_CAM} = 0x1$$

[Table 6-58](#) lists the registers to configure the camera subsystem clock configuration step.

**Table 6-58. Camera ISP PRCM Registers Settings**

| Register Name      | Address     | Value Description        |
|--------------------|-------------|--------------------------|
| PRCM.CM_CLKSEL_CAM | 0x4800 4F40 | DPLL4 divisor set to 0x4 |
| PRCM.CM_FLCKEN_CAM | 0x4800 4F00 | Enable CAM_FCLK          |
| PRCM.CM_ICLKEN_CAM | 0x4800 4F10 | Enable CAM_ICLK          |

### 6.5.2 Programming the CSI1/CCP2B or CSI2 Receiver Associated PHY

#### 6.5.2.1 Camera ISP CSIPHY Initialization for Work With CSI2 Receiver

To fully initialize the CSIPHY, perform the following steps:

1. Configure all CSI2 receiver registers to receive signals/data from the CSIPHY:
  - (a) Configure all necessary CSI2 registers:
    - (i) Set [CSI2\\_COMPLEXIO\\_CFG1\[10:8\] DATA2\\_POSITION](#).

- (ii) Set [CSI2\\_COMPLEXIO\\_CFG1\[6:4\]](#) DATA1\_POSITION.
- (iii) Set [CSI2\\_COMPLEXIO\\_CFG1\[2:0\]](#) CLOCK\_POSITION.
- (iv) Set CONTROL\_CAMERA\_PHY\_CTRL[1:0] R\_CONTROL\_CAMERA2\_PHY\_CAMMODE or CONTROL\_CAMERA\_PHY\_CTRL[3:2] R\_CONTROL\_CAMERA1\_PHY\_CAMMODE.

**CAUTION**

This must be done before the CSIPHY is active.

## 2. CSIPHY and link initialization sequence:

### (a) Deassert the CSIPHY reset:

- (i) Set [CSI2\\_COMPLEXIO\\_CFG1\[30\]](#) RESET\_CTRL to 0x1.

### (b) The following registers can be set only after deasserting the CSIPHY reset, and before asserting the ForceRxMode signal:

- [CSIPHY\\_REG0](#)
- [CSIPHY\\_REG1](#)
- [CSIPHY\\_REG2](#)

### (c) Assert the ForceRxMode signal:

- (i) Set [CSI2\\_TIMING\[15\]](#) FORCE\_RX\_MODE\_IO1 to 0x1.

### (d) Connect the pulldown on the link (DP/DN) by asserting the respective PIPD\* signals (PIPDL\* = 0):

- For CSIPHY1: Pull down on signals through padconf registers:
  - cam\_d6:
    - CONTROL\_PADCONF\_CAM\_D5[24] INPUTENABLE1 = 0x1
    - CONTROL\_PADCONF\_CAM\_D5[20] PULLTYPESELECT1 = 0x0
    - CONTROL\_PADCONF\_CAM\_D5[19] PULLUDENABLE1 = 0x1
  - cam\_d7:
    - CONTROL\_PADCONF\_CAM\_D7[8] INPUTENABLE0 = 0x1
    - CONTROL\_PADCONF\_CAM\_D7[4] PULLTYPESELECT0 = 0x0
    - CONTROL\_PADCONF\_CAM\_D7[3] PULLUDENABLE0 = 0x1
  - cam\_d8:
    - CONTROL\_PADCONF\_CAM\_D7[24] INPUTENABLE1 = 0x1
    - CONTROL\_PADCONF\_CAM\_D7[20] PULLTYPESELECT1 = 0x0
    - CONTROL\_PADCONF\_CAM\_D7[19] PULLUDENABLE1 = 0x1
  - cam\_d9:
    - CONTROL\_PADCONF\_CAM\_D9[8] INPUTENABLE0 = 0x1
    - CONTROL\_PADCONF\_CAM\_D9[4] PULLTYPESELECT0 = 0x0
    - CONTROL\_PADCONF\_CAM\_D9[3] PULLUDENABLE0 = 0x1
- For CSIPHY2: Pull down on signals through padconf registers:
  - cam\_d0:
    - CONTROL\_PADCONF\_CAM\_FLD[24] INPUTENABLE1 = 0x1
    - CONTROL\_PADCONF\_CAM\_FLD[20] PULLTYPESELECT1 = 0x0
    - CONTROL\_PADCONF\_CAM\_FLD[19] PULLUDENABLE1 = 0x1
  - cam\_d1:
    - CONTROL\_PADCONF\_CAM\_D1[8] INPUTENABLE0 = 0x1
    - CONTROL\_PADCONF\_CAM\_D1[4] PULLTYPESELECT0 = 0x0
    - CONTROL\_PADCONF\_CAM\_D1[3] PULLUDENABLE0 = 0x1

- csi2\_dx0:
  - CONTROL\_PADCONF\_CSI2\_DX0[8] INPUTENABLE0 = 0x1
  - CONTROL\_PADCONF\_CSI2\_DX0[4] PULLTYPESELECT0 = 0x0
  - CONTROL\_PADCONF\_CSI2\_DX0[3] PULLUDENABLE0 = 0x1
- csi2\_dy0:
  - CONTROL\_PADCONF\_CSI2\_DX0[24] INPUTENABLE1 = 0x1
  - CONTROL\_PADCONF\_CSI2\_DX0[20] PULLTYPESELECT1 = 0x0
  - CONTROL\_PADCONF\_CSI2\_DX0[19] PULLUDENABLE1 = 0x1
- csi2\_dx1:
  - CONTROL\_PADCONF\_CSI2\_DX1[8] INPUTENABLE0 = 0x1
  - CONTROL\_PADCONF\_CSI2\_DX1[4] PULLTYPESELECT0 = 0x0
  - CONTROL\_PADCONF\_CSI2\_DX1[3] PULLUDENABLE0 = 0x1
- csi2\_dy1:
  - CONTROL\_PADCONF\_CSI2\_DX1[24] INPUTENABLE1 = 0x1
  - CONTROL\_PADCONF\_CSI2\_DX1[20] PULLTYPESELECT1 = 0x0
  - CONTROL\_PADCONF\_CSI2\_DX1[19] PULLUDENABLE1 = 0x1

## (e) Power up the CSIPHY:

- (i) Set **CSI2\_COMPLEXIO\_CFG1**[28:27] PWR\_CMD to 0x1.

## (f) Check that the state status reaches the ON state:

- **CSI2\_COMPLEXIO\_CFG1**[26:25] PWR\_STATUS = 0x1

## (g) Wait for STOPSTATE = 1 (for all enabled lane modules):

- (i) The timer is set through the **CSI2\_TIMING**[14:0] bit field. The reset value can be kept.
- (ii) Wait until **CSI2\_TIMING**[15] FORCE\_RX\_MODE\_IO1 = 0x0. It is automatically put at 0 when all enabled lanes are in STOPSTATE and the timer is finished.

## (h) Release PIPD\* (= 1):

- For CSIPHY1: Pull up on signals through padconf registers:
  - cam\_d6:
    - CONTROL\_PADCONF\_CAM\_D5[20] PULLTYPESELECT1 = 0x1
  - cam\_d7:
    - CONTROL\_PADCONF\_CAM\_D7[4] PULLTYPESELECT0 = 0x1
  - cam\_d8:
    - CONTROL\_PADCONF\_CAM\_D7[20] PULLTYPESELECT1 = 0x1
  - cam\_d9:
    - CONTROL\_PADCONF\_CAM\_D9[4] PULLTYPESELECT0 = 0x1
- For CSIPHY2: Pull up on signals through padconf registers:
  - cam\_d0:
    - CONTROL\_PADCONF\_CAM\_FLD[20] PULLTYPESELECT1 = 0x1
  - cam\_d1:
    - CONTROL\_PADCONF\_CAM\_D1[4] PULLTYPESELECT0 = 0x1
  - csi2\_dx0:
    - CONTROL\_PADCONF\_CSI2\_DX0[4] PULLTYPESELECT0 = 0x1
  - csi2\_dy0:
    - CONTROL\_PADCONF\_CSI2\_DX0[20] PULLTYPESELECT1 = 0x1
  - csi2\_dx1:
    - CONTROL\_PADCONF\_CSI2\_DX1[4] PULLTYPESELECT0 = 0x1
  - csi2\_dy1:
    - CONTROL\_PADCONF\_CSI2\_DX1[19] PULLTYPESELECT1 = 0x1

- CONTROL\_PADCONF\_CSI2\_DX1[20] PULLTYPESELECT1 = 0x1
  - (i) The CSIPHY is initialized and ready/active in CSI2 mode.

### 6.5.2.2 Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver

To fully initialize the CSIPHY, perform the following steps:

1. Configure all CSI1/CCP2B receiver registers to receive signals/data from the CSIPHY:
  - (a) Configure all CSI1/CCP2B registers:
    - (i) Set **CSI2\_COMPLEXIO\_CFG1[10:8]** DATA2\_POSITION.  
CCP2 mode for work with CSIPHY1:  
0x0: Not used/connected  
CCP2 mode for work with CSIPHY2:  
0x0: Not used/connected
    - (ii) Set **CSI2\_COMPLEXIO\_CFG1[6:4]** DATA1\_POSITION.  
CCP2 mode for work with CSIPHY1:  
0x1: Data lane 1 is at position 2.  
0x2: Data lane 1 is at position 1.  
CCP2 mode for work with CSIPHY2:  
0x1: Data lane 1 is at position 2.  
0x2: Data lane 1 is at position 1.
    - (iii) Set **CSI2\_COMPLEXIO\_CFG1[2:0]** CLOCK\_POSITION.  
CCP2 mode for work with CSIPHY1:  
0x1: Clock lane is at position 2.  
0x5: Clock lane is at position 1.  
CCP2 mode for work with CSIPHY2:  
0x1: Clock lane is at position 2.  
0x5: Clock lane is at position 1.
    - (iv) Set CONTROL\_CAMERA\_PHY\_CTRL[1:0] R\_CONTROL\_CAMERA2\_PHY\_CAMMODE or  
CONTROL\_CAMERA\_PHY\_CTRL[3:2] R\_CONTROL\_CAMERA1\_PHY\_CAMMODE.

**CAUTION**

This must be done before the CSIPHY is active.

- (v) Set CONTROL\_CAMERA\_PHY\_CTRL[4] R\_CONTROL\_CSI1\_RX\_SEL.

**CAUTION**

This must be done before the CSIPHY is active.

2. CSIPHY and link initialization sequence:

- (a) Deassert the CSIPHY reset:
  - (i) Set **CSI2\_COMPLEXIO\_CFG1[30]** RESET\_CTRL to 0x1.
- (b) Assert the ForceRxMode signal:
  - (i) Set **CSI2\_TIMING[15]** FORCE\_RX\_MODE\_IO1 to 0x1.
- (c) Power up the CSIPHY:
  - (i) Set **CSI2\_COMPLEXIO\_CFG1[28:27]** PWR\_CMD to 0x1.
- (d) Check that the state status reaches the ON state:

- [CSI2\\_COMPLEXIO\\_CFG1\[26:25\]](#) PWR\_STATUS = 0x1.
- (e) Release the ForceRxMode signal:
  - (i) Set [CSI2\\_TIMING\[15\]](#) FORCE\_RX\_MODE\_IO1 to 0x0.
- (f) CSIPHY is initialized and ready/active in CSI1/CCP2B mode.

### 6.5.3 Programming the CSI1/CCP2B Receiver

This section describes the programming model of the CSI1/CCP2B receiver.

#### 6.5.3.1 Camera ISP CSI1/CCP2B Hardware Setup/Initialization

This section discusses the configuration of the CSI1/CCP2B receiver required before image capture can begin.

##### 6.5.3.1.1 Camera ISP CSI1/CCP2B Reset Behavior

On hardware or software reset of the camera ISP, all registers in the CSI1/CCP2B receiver are reset to their reset values.

#### 6.5.3.2 Camera ISP CSI1/CCP2B Event and Status Checking

When an event occurs, the corresponding bit in the [CCP2\\_LC01\\_IRQSTATUS](#) (or [CCP2\\_LC23\\_IRQSTATUS](#)) register is set. Each event can be individually masked using the [CCP2\\_LC01\\_IRQENABLE](#) register ([CCP2\\_LC23\\_IRQENABLE](#)). Masked events are not transmitted to the interrupt lane, but the [CCP2\\_LC01\\_IRQSTATUS](#) register (or [CCP2\\_LC23\\_IRQSTATUS](#)) is updated.

Events transmitted to the interrupt lane can be mapped to the ARM or DSP by unmasking the ISP\_CSIB bit in the ISP\_IRQxENABLE (x = 0, 1). Depending on whether the event is mapped to the ARM or DSP register, to clear an event, the following actions are required:

- Clear the event at the CSI1/CCP2B receiver level by writing 1 to the corresponding bit in the [CCP2\\_LC01\\_IRQSTATUS](#) register (or [CCP2\\_LC23\\_IRQSTATUS](#)).
- Clear the event at ISP level by writing 1 to the corresponding bit ISP\_CSI1 in the ISP\_IRQxENABLE (x = 0, 1) register.

#### 6.5.3.3 Camera ISP CSI1/CCP2B Register Accessibility During Frame Processing

There are two types of register accesses in the CSI1/CCP2B receiver:

- Shadowed registers:
  - These registers/fields can be read and written (if the field is writable) at any time. However, written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.
  - The shadowed registers are:
    - [CCP2\\_LCx\\_CTRL](#)
    - [CCP2\\_LCx\\_CODE](#)
    - [CCP2\\_LCx\\_STAT\\_START](#)
    - [CCP2\\_LCx\\_STAT\\_SIZE](#)
    - [CCP2\\_LCx\\_SOF\\_ADDR](#)
    - [CCP2\\_LCx\\_EOF\\_ADDR](#)
    - [CCP2\\_LCx\\_DAT\\_SIZE](#)
    - [CCP2\\_LCx\\_DAT\\_PING\\_ADDR](#)
    - [CCP2\\_LCx\\_DAT\\_PONG\\_ADDR](#)
    - [CCP2\\_LCx\\_DAT\\_OFST](#)
- Busy-locked registers:
  - These registers/fields must not be written if the module is busy.

- All register fields not listed as shadowed are busy-writable registers.

#### 6.5.3.4 Camera ISP CSI1/CCP2B Enable/Disable the Hardware

The CSI1/CCP2B receiver is globally controlled by the [CCP2\\_CTRL](#) register. The bit fields in this register must not be modified when the CSI1/CCP2B interface is active (except [CCP2\\_CTRL](#) [0] IF\_EN):

- To activate the CSI1/CCP2B interface:
  - [CCP2\\_CTRL](#) [0] IF\_EN = 0x1
  - Data acquisition starts on the following FSC synchronization code. Writing [CCP2\\_CTRL](#) [0] IF\_EN = 0x1 resets the output FIFO of the module; the reset is caused by the 0-to-1 edge transition.
- To disable the CSI1/CCP2B interface:
  - [CCP2\\_CTRL](#) [0] IF\_EN = 0x0
  - The interface is disabled immediately if [CCP2\\_CTRL](#) [3] FRAME = 0x0.
  - If [CCP2\\_CTRL](#) [3] FRAME = 0x1 and [CCP2\\_LCx\\_CTRL](#)[19] CRC\_EN = 0x0, the interface is disabled after the FEC synchronization code is received.
  - If [CCP2\\_CTRL](#)[3] FRAME = 0x1 and [CCP2\\_LCx\\_CTRL](#)[19] CRC\_EN = 0x1, the interface is disabled only after the 16-bit CRC checksum and 16-bit pad data is received.
  - Before disabling the interface (IF\_EN=0) it is advised to disable all active channels by writing [CCP2\\_LCx\\_CTRL](#)[0] CHAN\_EN = 0x0. Otherwise, if IF\_EN = 0 is set during a vertical blanking period, the reception continues until the FEC synchronization code is received for all active channels.

#### 6.5.3.5 Camera ISP CSI1/CCP2B Select the Signaling Scheme

The [CCP2\\_CTRL](#)[1] PHY\_SEL bit selects whether the data/strobe or data/clock signaling scheme is used. See [Table 6-22](#) for the correct settings as a function of the image sensor class. Setting [CCP2\\_CTRL](#) [1] PHY\_SEL = 0x1 has no effect if [CCP2\\_CTRL](#) [4] MODE = 0x0.

#### 6.5.3.6 Camera ISP CSI1/CCP2B Control of the PHY

The [CCP2\\_CTRL](#) [2] IO\_OUT\_SEL bit selects the output mode of the CSI1/CCP2B receiver associated PHY(could be either CSIPHY1 or CSI2PHY2), which must be set to 1 for parallel only.

For information about initializing and configuring the CSIPHY that is associated with the CSI1/CCP2B receiver, see [Section 6.5.2.2, Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver](#).

#### 6.5.3.7 Camera ISP CSI1/CCP2B Select the Mode: MIPI CSI1 or CCP2B

The [CCP2\\_CTRL](#)[4] MODE bit selects whether the CCP2B module works in MIPI CSI1 or CCP2-compatible mode. Setting [CCP2\\_CTRL](#)[4] MODE = 0x0 disables the CCP2-specific features: data/strobe, CRC, logical channels, RAW6 and RAW7 data formats. The following bits have no effect when [CCP2\\_CTRL](#)[4] MODE = 0x0: [CCP2\\_CTRL](#)[1] PHY\_SEL, [CCP2\\_LCx\\_CTRL](#)[19] CRC\_EN, [CCP2\\_LCx\\_CTRL](#)[0] CHAN\_EN (x = 1 to 3). Furthermore, [CCP2\\_LCx\\_CTRL](#)[7:2] FORMAT values 8, 9, 10, 12, 13, 14, 17, 18, 21, and 25 have no effect: no data are output. MIPI CSI1 is the default mode of the module.

#### 6.5.3.8 Camera ISP CSI1/CCP2B Burst Settings

The [CCP2\\_CTRL](#)[6:5] BURST bit field forces the burst behavior of the CSI1/CCP2B receiver. The module can be forced to perform single 64-bit requests or bursts of 2x, 4x, and 8x 64 bits. The burst size must never exceed the output FIFO size. The output FIFO size can be read by reading the [CCP2\\_GNQ](#)[4:2] FIFODEPTH bit field.

#### 6.5.3.9 Camera ISP CSI1/CCP2B Debug Mode

Use the [CCP2\\_CTRL](#) [7] DBG\_EN bit to enable the debug mode:

- During debug mode, the input comes from the [CCP2\\_DBG](#) register, not from the CSI1/CCP2B physical interface. The full CSI1/CCP2B receiver functionality can be debugged in debug mode. Full 32-bit values must always be written to the [CCP2\\_DBG](#) register.
- The following bits have no effect during debug mode:
  - [CCP2\\_CTRL](#) [0] IF\_EN
  - [CCP2\\_CTRL](#) [1] PHY\_SEL
  - [CCP2\\_CTRL](#) [2] IO\_OUT\_SEL
- The following examples apply to the [CCP2\\_DBG](#) register:
  - Synchronization codes: [CCP2\\_DBG](#) = 0xFF000000
  - To send the RAW12 pixels 0x673, 0x452, 0x01d, 0xe fc, 0xab0, 0x891, 0x326, and 0x547, write [CCP2\\_DBG](#) = 0x01234567 followed by [CCP2\\_DBG](#) = 0x89abcdef [CCP2\\_DBG](#) = 0x76543210.

---

**NOTE:** Each write to the [CCP2\\_DBG](#) register sends a full 32-bit word through the CSI1/CCP2B receiver hardware. When 8- or 16-bit writes are performed to the register, the previous 32-bit value is merged with the newly written one. When the driver writes, for example, 0x01234567 followed by 0x000000FF with BYTEEN = 0x1 (this write from the MPU subsystem informs that only 8 bits are written), the CSI1/CCP2B receiver pipeline gets 0x01234567 followed by 0x012345FF.

---

#### 6.5.3.10 Camera ISP CSI1/CCP2B Video Port

- Set the video-port output frequency:
  - [CCP2\\_CTRL](#) [9:8] VP\_OUT\_CTRL
  - The video-port output frequency varies from CAM\_ICLK to CAM\_ICLK/4 MHz. CAM\_ICLK is the CSI1/CCP2B receiver functional and interface clock. The reset value selects CAM\_ICLK/2.
- [CCP2\\_CTRL](#) [11] VP\_ONLY\_EN:
  - Controls whether the video-port output is the only output interface enabled and applies for all channels.
  - When [CCP2\\_CTRL](#) [11] VP\_ONLY\_EN = 0x1, the data are output only to the video port; the interface master port is not used. The two parts of the frame (embedded data and pixel data) are output to the video port (instead of pixel data to video port and embedded data to interconnect).
    - The video port outputs the embedded data defined by the [CCP2\\_LCx\\_STAT\\_START](#) and [CCP2\\_LCx\\_STAT\\_SIZE](#) registers without decompression.
    - The video port outputs the pixel data defined by the [CCP2\\_LCx\\_DAT\\_START](#) and [CCP2\\_LCx\\_DAT\\_SIZE](#) registers.
  - The pixel data are decompressed according to the settings of the [CCP2\\_LCx\\_CTRL](#) [7:2] FORMAT bit field. [Table 6-59](#) summarizes the behavior of the video port as a function of the [CCP2\\_LCx\\_CTRL](#) [7:2] FORMAT bit field.

**Table 6-59. Camera ISP CSI1/CCP2B CCP2\_LCx\_CTRL[7:2] FORMAT and CCP2\_CTRL[11] VP\_ONLY\_EN = 1 Settings**

| <a href="#">CCP2_LCx_CTRL</a> [7:2] Format | Video-Port Behavior                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| YUV422 + VP or RAW8 + VP                   | The incoming data are 8 bits. The pixel data are not compressed.<br>The embedded data are transmitted to the CCDC module on 8 bits (DATA[7:0]). The pixel data are not decompressed.<br>The pixel data are transmitted to the CCDC module on 8 bits (DATA[7:0]).                                                        |
| RAW12 + VP                                 | The incoming data are 12 bits. The pixel data are not compressed.<br>The embedded data are transmitted to the CCDC module on 12 bits (DATA[11:0]). The pixel data are reconstructed in the receiver.<br>The pixel data are transmitted to the CCDC module on 12 bits (DATA[11:0]). The pixel data are not decompressed. |

- Control the video-port pixel clock polarity:
  - If **CCP2\_CTRL[12]** VP\_CLK\_POL = 0x0, the CSI1/CCP2B receiver module writes the data on the video port on the pixel-clock falling edge. The module connected to the VP samples the data on the pixel clock rising edge.
  - If **CCP2\_CTRL[12]** VP\_CLK\_POL = 0x1, the CSI1/CCP2B receiver module writes the data on the video port on the pixel-clock raising edge. The module connected to the VP samples the data on the pixel clock falling edge. [Figure 6-105](#) shows the **CCP2\_CTRL**.VP\_CLK\_POL settings.

**Figure 6-105. Camera ISP CSI1/CCP2B CCP2\_CTRL.VP\_CLK\_POL Settings**

#### 6.5.3.11 Camera ISP CSI1/CCP2B Logical Channels

The CCP2B receiver supports simultaneous logical channels. Each logical channel is controlled independently with its own set of registers. The four sets of registers are identical, but some reset values are different.

The same description applies to all other logical channels. Logical channel LC $x$  means LC0, LC1, LC2, or LC3.

All the registers in this section can be modified at any time. However, the modifications apply only from the start of the following frame.

#### 6.5.3.12 Camera ISP CSI1/CCP2B Controls

The logical channel is controlled by the CCP2\_LCx\_CTRL register.

The logical channel is enabled by setting CCP2\_LCx\_CTRL[0] CHAN\_EN = 0x1. By default, all logical channels except logical channel 0 are disabled. Only the pixel data of one logical channel can go to the Video processing hardware; the SOF and EOF lines are always sent to memory through the interconnect interface. Setting CCP2\_LCx\_CTRL[0] CHAN\_EN ( $x=1$ ), CCP2\_LCx\_CTRL[0] CHAN\_EN ( $x=2$ ), or CCP2\_LCx\_CTRL[0] CHAN\_EN = 0x1 ( $x=3$ ) has no effect if CCP2\_CTRL[4] MODE = 0x0.

#### 6.5.3.13 Camera ISP CSI1/CCP2B Region of Interest

The CCP2\_LCx\_CTRL[1] REGION\_EN bit enables the region-of-interest feature (SOF lines, pixel data, and EOF lines):

- If enabled, register settings set the position and size of each region; all data not in a region of interest are ignored.
- If disabled, all data in the frame are output. CCP2\_LCx\_CTRL[1] REGION\_EN is set to 0x0 for a JPEG bitstream.

#### 6.5.3.14 Camera ISP CSI1/CCP2B CRC

The CRC can be enabled or disabled with CCP2\_LCx\_CTRL[19] CRC\_EN. If the received checksum and the computed checksum do not match, an interrupt is triggered: the corresponding event is LC $x$ \_CRC\_IRQ. Setting CCP2\_LCx\_CTRL[19] CRC\_EN = 0x1 has no effect if CCP2\_CTRL[4] MODE = 0x0.

#### 6.5.3.15 Camera ISP CSI1/CCP2B Destination Format

- Control the destination format:
  - The CSI1/CCP2B receiver reformats received data to store it in memory or to send it to the Videp processing hardware.
  - CCP2\_LCx\_CTRL[7:2] FORMAT controls destination-data format:

- EXP8 = Data expansion to 8 bits, padding with zeros
- EXP16 = Data expansion to 16 bits, padding with alpha or zeros [CCP2\\_CTRL\[15:8\]](#) ALPHA can be used to set an alpha value. For RGB444 + EXP16:
  - data\_out[31:28]=ALPHA[3:0] and data\_out[27:16]=RGB444
  - data\_out[15:12]=ALPHA[3:0] and data\_out[11:0]=RGB444
- EXP32 = Data expansion to 32 bits, padding with alpha. [CCP2\\_CTRL\[15:8\]](#) ALPHA can be used to set an alpha value. For RGB888 + EXP32: data\_out[31:24]=ALPHA[7:0] and data\_out[23:0]=RGB888
- FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
- VP = Output to the Video processing hardware is enabled.

#### 6.5.3.16 Camera ISP CSI1/CCP2B Frame Acquisition

- Program the number of frames that the CSI1/CCP2B receiver acquires:
  - [CCP2\\_LCx\\_CTRL \[31:24\]](#) COUNT
  - Writes to the COUNT bit field are controlled by the [CCP2\\_LCx\\_CTRL \[16\]](#) COUNT\_UNLOCK bit.
  - If COUNT = 0x0, the counter is free-running; frame acquisition lasts until disabled by the programmer. It is the default value.
  - COUNT controls the number of frames to acquire. The values range between 1 and 255. The COUNT value is decremented after each frame received. The software can read this value to acquire the number of frames that remain to be acquired.

After the correct number of frames is received, acquisition is automatically disabled ([CCP2\\_LCx\\_CTRL \[0\]](#) CHAN\_EN = 0x0) and the COUNT\_IRQ interrupt is triggered. The programmer can reenable the acquisition by resetting [CCP2\\_LCx\\_CTRL \[0\]](#) CHAN\_EN to 0x1.

[CCP2\\_LCx\\_CTRL \[17\]](#) PING\_PONG indicates whether the PING address ([CCP2\\_LCx\\_DAT\\_PING\\_ADDR](#)) or PONG address ([CCP2\\_LCx\\_DAT\\_PONG\\_ADDR](#)) was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in [CCP2\\_CTRL \[0\]](#) IF\_EN, the pixel data are written in the PING buffer and [CCP2\\_LCx\\_CTRL \[17\]](#) PING\_PONG = 0x1 (PONG). After the first FEC synchronization code is received, the pixel data are written in the PONG buffer and [CCP2\\_LCx\\_CTRL \[17\]](#) PING\_PONG = 0x0 (PING). [CCP2\\_LCx\\_CTRL \[17\]](#) PING\_PONG toggles after every FEC synchronization code.

#### 6.5.3.17 Camera ISP CSI1/CCP2B Synchronization Codes

The FSC, FEC, LSC, and LEC synchronization codes have default values given by the CCP2B specification. Also, each logical channel is identified by a default identifier.

The [CCP2\\_LCx\\_CODE](#) register enables overwriting of the default values: [CCP2\\_LCx\\_CODE \[11:8\]](#) FSC, [CCP2\\_LCx\\_CODE \[15:12\]](#) FEC, [CCP2\\_LCx\\_CODE \[3:0\]](#) LSC, and [CCP2\\_LCx\\_CODE \[7:4\]](#) LEC overwrite the 4 LSBs of the 32-bit synchronization codes. The default values should not be modified.

#### 6.5.3.18 Camera ISP CSI1/CCP2B Status Data

The SOF and EOF status lines can be output to memory.

The SOF and EOF status lines always cover full lines. No register settings enable the setting of width.

The [CCP2\\_LCx\\_STAT\\_START](#) register enables the setting of the vertical start position of the SOF and EOF status lines. Because the SOF status line comes first in the CSI1/CCP2B frame, [CCP2\\_LCx\\_STAT\\_START \[11:0\]](#) SOF = 0x0.

The [CCP2\\_LCx\\_STAT\\_SIZE](#) register enables the setting of the numbers of SOF and EOF status lines. If [CCP2\\_LCx\\_STAT\\_SIZE \[11:0\]](#) SOF = 0x0 and [CCP2\\_LCx\\_STAT\\_SIZE \[27:16\]](#) EOF = 0x0, no status data are output.

Figure 6-106 shows the SOF and EOF region settings. The SOF and EOF status lines and the pixel data must not overlap, but can be consecutive. Figure 6-106 shows the SOF and EOF region settings.

**Figure 6-106. Camera ISP CSI1/CCP2B SOF and EOF Region Settings**

camisp-201

The 32-bit destination address of the SOF status lines is set by the [CCP2\\_LCx\\_SOF\\_ADDR](#) register.

**NOTE:** The destination address must be aligned on a 32-byte boundary; the address 5 LSBs are ignored. The SOF lines are packed together at the destination address.

The 32-bit destination addresses of the EOF status lines are set by the [CCP2\\_LCx\\_EOF\\_ADDR](#) register.

**NOTE:** The destination address must be aligned on a 32-byte boundary; the address 5 LSBs are ignored. The EOF lines are packed together at the destination address.

**NOTE:** The CSI1/CCP2B receiver does not modify the data in the SOF and EOF status lines. The data are received and written with no modifications.

#### 6.5.3.19 Camera ISP CSI1/CCP2B Pixel Data Region

Pixel data can be output to memory or to the Video processing hardware.

The pixel data region covers full lines. The [CCP2\\_LCx\\_DAT\\_SIZE](#) register sets the horizontal size of the pixel region. The vertical size is expressed in lines.

The [CCP2\\_LCx\\_DAT\\_START](#) register enables the setting of the vertical start position of the pixel data. The vertical start position is expressed in lines.

[Figure 6-107](#) shows the pixel region settings.

**Figure 6-107. Camera ISP CSI1/CCP2B Pixel Data Region Settings**

camisp-202

The 32-bit destination addresses of the pixel data are set by the `CCP2_LCx_DAT_PING_ADDR` and `CCP2_LCx_DAT_PONG_ADDR` registers.

**NOTE:** The destination address must be aligned on a 32-byte boundary; the address 5 LSBs are ignored. The pixel data lines are packed together at the destination address.

It is possible to perform double-buffering (ping-ponging) at the destination by setting different addresses in the [CCP2\\_LCx\\_DAT\\_PING\\_ADDR](#) and [CCP2\\_LCx\\_DAT\\_PONG\\_ADDR](#) registers. It is possible to disable double-buffering by setting up the same address in both registers. The [CCP2\\_LCx\\_CTRL](#) [17] PING\_PONG status bit must be used by the software to determine which address contains the latest frame.

A destination pitch controls the address jump between the address of the first pixel of the previous line and the address of the first pixel of the current line. The destination pitch is set in bytes with the [CCP2\\_LCx\\_DAT\\_OFST](#) register. It applies for [CCP2\\_LCx\\_DAT\\_PING\\_ADDR](#) and [CCP2\\_LCx\\_DAT\\_PONG\\_ADDR](#).

**NOTE:** The destination pitch must be a multiple of 32 bytes; the address 5 LSBs are ignored.

The use of [CCP2\\_LCx\\_DAT\\_OFST](#) is limited to the following destination data formats:

- YUV422 little endian
  - YUV422 big endian

- RGB444 + EXP16
- RGB565
- RGB888 + EXP32

For all other data formats, the [CCP2\\_LCx\\_DAT\\_OFST](#) register is ignored (equivalent to [CCP2\\_LCx\\_DAT\\_OFST](#) = 0x0).

The destination data format is set with the [CCP2\\_LCx\\_CTRL](#) [7:2] FORMAT bit field.

For the PING frame:

- @Line0 = [CCP2\\_LCx\\_DAT\\_PING\\_ADDR](#)
- @Line1 = @Line0 + [CCP2\\_LCx\\_DAT\\_OFST](#)
- @Line2 = @Line1 + [CCP2\\_LCx\\_DAT\\_OFST](#)

For the PONG frame:

- @Line0 = [CCP2\\_LCx\\_DAT\\_PONG\\_ADDR](#)
- @Line1 = @Line0 + [CCP2\\_LCx\\_DAT\\_OFST](#)
- @Line2 = @Line1 + [CCP2\\_LCx\\_DAT\\_OFST](#)

When [CCP2\\_LCx\\_DAT\\_OFST](#) = 0x0, the lines are written contiguously in memory. The destination pitch enables 2D transfers; it is required to write the pixel data directly in the frame buffer, for instance.

In such cases, [CCP2\\_LCx\\_DAT\\_OFST](#) = FRAME\_BUFFER\_WIDTH. Figure 6-108 shows the pixel data settings.

**Figure 6-108. Camera ISP CSI1/CCP2B Pixel Data Destination Settings**

camisp-203

### 6.5.3.20 Camera ISP CSI1/CCP2B Memory Read Channel

#### 6.5.3.20.1 Camera ISP CSI1/CCP2B Write Data From Sensor to Memory

Data can be captured from the sensor using any logical channel. To keep the native data format, the channel format must be set to YUV422 little-endian format.

### 6.5.3.20.2 Camera ISP CSI1/CCP2B Read Data from Memory

By default, the memory read channel is disabled. Before the memory read channel can be enabled ([CCP2\\_LCM\\_CTRL \[0\]](#) CHAN\_EN = 1), all logical channels must be disabled ([CCP2\\_CTRL \[0\]](#) IF\_EN = 0) and required registers must be configured.

When the [CCP2\\_CTRL \[3\]](#) FRAME bit is set, software must wait until disabling of the physical interface is effective before enabling the memory read channel.

The SBL image data read port is shared by the PREVIEW and CSI1/CCP2B receiver modules. The read port must be affected to the CSI1/CCP2B receiver module by writing 1 to the [ISP\\_CTRL\[27\]](#) SBL\_SHARED\_RPORTA bit. The programmer must ensure that the PREVIEW module does not use this port before switching to the CSI1/CCP2B module.

The burst size must be configured to 32 x 64-bit bursts, using the [CCP2\\_LCM\\_CTRL \[7:5\]](#) BURST\_SIZE register.

Firmware must then configure the source data format, location, and framing. In addition to the [CCP2\\_LCM\\_HSIZE \[11:0\]](#) SKIP and [CCP2\\_LCM\\_HSIZE \[27:16\]](#) COUNT registers, the firmware must specify the amount of data to be fetched from memory. This value is set in 64-bit word steps and must be a multiple of 32 bytes (four words of 64 bits). The value is computed with the following formula:

$$\text{HWORDS} = 4 \times \text{ceil}((\text{SKIP} + \text{COUNT}) \times \text{bits\_per\_pixel})/(8 \times 32)) \quad (3)$$

The [CCP2\\_LCM\\_SRC\\_ADDR](#) and [CCP2\\_LCM\\_SRC\\_OFST](#) registers must be aligned on 32-byte boundaries for correct operation. For best performance, both registers must be aligned on 256-byte boundaries.

Example:

- [CCP2\\_LCM\\_CTRL \[7:5\]](#) BURST\_SIZE is set to 32 x 64 bits
- [CCP2\\_LCM\\_HSIZE \[11:0\]](#) SKIP = 0
- [CCP2\\_LCM\\_HSIZE \[27:16\]](#) COUNT = 1000
- [CCP2\\_LCM\\_CTRL \[23\]](#) SRC\_PACK = YES
- [CCP2\\_LCM\\_CTRL \[18:16\]](#) SRC\_FORMAT = RAW6
- [CCP2\\_LCM\\_PREFETCH \[13:3\]](#) HWORDS = 96 (=94)

Setting the size to 94 produces the following burst sequence: 32, 32, 16, 8, and 4 (5 interconnect requests). However, when it is set to 96, the burst sequence is 32, 32, and 32 (3 interconnect requests).

By default, only MIPI CSI1 data formats are supported. To support CCP2 formats, [CCP2\\_CTRL \[4\]](#) MODE must be set by firmware.

Data is sent to memory when [CCP2\\_LCM\\_CTRL \[2\]](#) DST\_PORT = 1; otherwise, it is sent to the video port. It is not possible to send data to the video port and memory concurrently. If data are sent to the video port, its clock frequency is selected with the [CCP2\\_CTRL \[31:15\]](#) FRACDIV bit field. Otherwise, the [CCP2\\_CTRL \[31:15\]](#) FRACDIV bit field is ignored.

---

**NOTE:** In a given scenario where data is sent to the video port and further down to ISP (CCDC and/or RSZ) to be processed, it is possible for CCP2 to stall the image signal processor by feeding too much data to CCDC and/or RSZ. At that time, the CCDC/RSZ FIFO overflow interrupt is raised. To prevent the processor from stalling, the VP clock must be lowered from [CCP2\\_CTRL\[31:15\]](#) FRACDIV.

---

The [CCP2\\_LCM\\_CTRL \[4:3\]](#) READ\_THROTTLE register can be used to reduce the bandwidth in memory-to-memory operation to prevent system overload. It has no effect when data are sent to the video port.

If the memory write port is used, the destination format and address must be configured.

Then the memory channel is enabled by setting [CCP2\\_LCM\\_CTRL \[0\]](#) CHAN\_EN = 1. After processing a full frame, this bit is automatically cleared by hardware and an EOF event is triggered.

## 6.5.4 Programming the CSI2 Receiver

### 6.5.4.1 Camera ISP CSI2 Enabling the Interface

The CSI2 interface is clocked by CSI2\_96\_FCLK, which is enabled by setting the PRCM.CM\_FCLKEN\_CAM[1] EN\_CSI2 bit register to 1.

### 6.5.4.2 Camera ISP CSI2 Reset Management

The CSI2 receiver accepts a general software reset, propagated throughout the hierarchy. This reset can be done to initialize the CSI2 receiver and the PHY and has the same effect as a hardware reset.

Figure 6-109 shows how to reset the CSI2 globally.

Figure 6-109. Camera ISP CSI2 Receiver Global Reset Flow Chart

camisp-252

NOTE: CSI2\_PHY\_CFG.RESET\_DONE is set to 1 only after the CSI2 receiver, CSI2 PHYs, and external camera sensor are initialized.

**NOTE:** Before setting the software reset bit to 1 in the [CSI2\\_SYSCONFIG](#) register, the user must have access to a CSI2 receiver register.

**NOTE:** The CSI2 protocol engine provides only the configuration bus clock when PHY registers are accessed. However, the PHY needs at least three configuration bus clock cycles (L4 interconnect clock) to come out of the reset state. Therefore, software must perform a dummy read of a PHY register (32 configuration bus clock pulses) to complete the PHY reset sequence.

### 6.5.4.3 Camera ISP CSI2 Enable Video/Picture Acquisition

To start a video/picture acquisition, perform the following steps:

1. Reset the CSI2 receiver module (see [Section 6.5.4.2, Reset Management](#)).
2. Configure the module power management: Set the [CSI2\\_SYSConfig\[13:12\]](#) MSTANDBY\_MODE bit field to 0x2 so the module tries to enter smart-standby mode during the vertical blanking period. The [CSI2\\_SYSConfig\[0\]](#) AUTO\_IDLE bit field keeps its reset value; by default, an automatic port clock gating strategy is applied based on port interface activity
3. Configure the interrupt generation as required using the [CSI2\\_IRQSTATUS](#) and [CSI2\\_IRQENABLE](#) registers. To enable context and/or PHY event reporting, enable the corresponding bit field in the [CSI2\\_IRQENABLE](#) register. If the enable bit is at 0, logging is still effective if an event occurs but is not reported to a higher level.
4. Configure the PHY interrupt generation as required using the [CSI2A\\_PHY\\_IRQSTATUS](#) and [CSI2\\_COMPLEXIO1\\_IRQENABLE](#) registers. If the enable bit is at 0, logging is still effective if an event occurs but is not reported to a higher level.
5. Initialize the PHY (see [Section 6.5.2.1, Camera ISP CSIPHY Initialization for Work With CSI2 Receiver](#)).
6. Set the [CSI2\\_CTRL\[2\]](#) ECC\_EN bit to 1 to activate ECC correction and error detection on short packets and packet headers. The ECC check corrects the packet if there is one error and generates an error if there is more than one error (unrecoverable error).
7. Start the CSI2 receiver by setting the [CSI2\\_CTRL\[0\]](#) IF\_EN bit to 1.
8. Configure the different contexts to be used (up to eight):
  - (a) Link the context to a virtual channel and a data type (see [Section 6.5.4.7, Linking a Context to a Virtual Channel and a Data Type](#)).
  - (b) Set the [CSI2\\_CTx\\_CTRL1\[26:23\]](#) FEC\_NUMBER bit field to 0x1 for a progressive video and to 0x2 for an interlaced video. For more information, see [Section 6.4.3.8, DMA Engine](#).
  - (c) Keep the [CSI2\\_CTx\\_CTRL1\[15:8\]](#) COUNT bit field and the [CSI2\\_CTx\\_CTRL1\[4\]](#) COUNT\_UNLOCK bit at their reset values (0x0 and 0, respectively) to capture an infinite number of frames (until the interface or the context is disabled).
  - (d) Set the [CSI2\\_CTx\\_CTRL1\[5\]](#) CS\_EN bit to enable the CRC checksum on long packet payload. This allows detection of errors, but cannot correct errors like the ECC for header and short packet. On error detection, an event is triggered (the [CSI2\\_CTx\\_IRQSTATUS\[5\]](#) CS IRQ bit).
  - (e) Configure the DMA engine for the current channel:
    - Configure the [CSI2\\_CTx\\_DAT\\_PING\\_ADDR\[31:5\]](#) ADDR bit field to set the ping frame address in memory.
    - Configure the [CSI2\\_CTx\\_DAT\\_PONG\\_ADDR\[31:5\]](#) ADDR bit field to set the pong frame address in memory. If not using a double-buffer mechanism, the ping and pong addresses must be equal so that all frames are stored at the same memory address).
    - Set the [CSI2\\_CTx\\_DAT\\_OFST\[15:5\]](#) OFST bit field to 0x0, so consecutive lines are stored consecutively in memory (image width and frame-buffer width are equal).

**NOTE:** Addresses given for PING and PONG frames are virtual addresses. Address translations are made on the camera MMU and on the Circular Buffer. For more information about the camera MMU module, see [Chapter 15, Memory Management Units](#).

- (f) Keep the [CSI2\\_CTx\\_CTRL3\[29:16\]](#) ALPHA bit field at its reset value (0x0) for RGB padding.
9. Enable the contexts to be used by setting the [CSI2\\_CTx\\_CTRL1\[0\]](#) CTX\_EN bit to 1.

### 6.5.4.4 Camera ISP CSI2 Disable Video/Picture Acquisition

There are two ways to end picture acquisition:

- Disable the corresponding context by writing 0 to the [CSI2\\_CTx\\_CTRL1\[0\]](#) CTX\_EN bit. This stops the acquisition for the current context. Other enabled contexts are still capturing frames and writing them in memory.

- Disable the CSI2 receiver interface by writing 0 to the [CSI2\\_CTRL\[0\]](#) IF\_EN bit. This can have an immediate effect if the [CSI2\\_CTRL\[3\]](#) FRAME bit is 0, or it can be effective after all the enabled contexts receive the FEC if the [CSI2\\_CTRL\[3\]](#) FRAME bit is 1.

#### 6.5.4.5 Camera ISP CSI2 Capture a Finite Number of Frames

The CSI2 receiver module can be configured to capture a finite number of frames. To configure the CSI2 receiver in this mode, perform the following steps:

1. Write 1 to the [CSI2\\_CTX\\_CTRL1\[4\]](#) COUNT\_UNLOCK bit to enable a write to the COUNT bit field.
2. Set the bit field to the number of frames the CSI2 receiver must capture. Valid values are 0 to 255; 0 is infinite capture and 1 to 255 defines the number of frames to capture.
3. Write 0 to the [CSI2\\_CTX\\_CTRL1\[4\]](#) COUNT\_UNLOCK bit to disable a write to the COUNT bit field.

During frame capture, the COUNT bit field is decremented by 1 at each frame capture. The software reads the COUNT bit field to know how many frames still must be captured.

The COUNT bit can be updated during capture if the COUNT\_UNLOCK is set to 1.

#### 6.5.4.6 Camera ISP CSI2 Configure a Periodic Event During Frame Acquisition

The CSI2 receiver can generate a periodic event. This line number is defined in the [CSI2\\_CTX\\_CTRL3\[15:0\]](#) LINE\_NUMBER bit field. The event can be generated once or multiple times per frame, depending on the [CSI2\\_CTX\\_CTRL1\[1\]](#) LINE\_MODULO bit value:

- If the LINE\_MODULO bit = 0, the event is generated when the line number corresponding to the LINE\_NUMBER bit field is received.
- If the LINE\_MODULO bit = 1, the event is generated when the line number received corresponds to a multiple of the LINE\_NUMBER value (LINE\_NUMBER is used as a modulo).

#### 6.5.4.7 Camera ISP CSI2 Linking a Context to a Virtual Channel and a Data Type

The CSI2 receiver supports eight contexts and the CSI2 protocol defines four virtual channels. Therefore, a CSI2 receiver context can be associated with a virtual channel and a data type. Virtual channels are defined by a 2-bit field. Valid data types for the CSI2 receiver with their associated values are described in [Table 6-60](#).

**Table 6-60. Camera ISP CSI2 Receiver-Supported Data Types**

| Value | Data Type                    |
|-------|------------------------------|
| 0x0   | Others                       |
| 0x12  | Embedded 8-bit nonimage data |
| 0x18  | YUV420 8-bit                 |
| 0x19  | YUV420 10-bit                |
| 0x1A  | YUV420 8-bit legacy          |
| 0x1C  | YUV420 8-bit + CSPS          |
| 0x1D  | YUV420 10-bit + CSPS         |
| 0x1E  | YUV422 8-bit                 |
| 0x1F  | YUV422 10-bit                |
| 0x22  | RGB565                       |
| 0x24  | RGB888                       |
| 0x28  | RAW6                         |
| 0x29  | RWA7                         |
| 0x2A  | RAW8                         |
| 0x2B  | RAW10                        |
| 0x2C  | RAW12                        |
| 0x2D  | RAW14                        |
| 0x33  | RGB666 + EXP32_24            |

**Table 6-60. Camera ISP CSI2 Receiver-Supported Data Types (continued)**

| Value | Data Type                                       |
|-------|-------------------------------------------------|
| 0x40  | USER_DEFINED_8_BIT_DATA_TYPE_1                  |
| 0x41  | USER_DEFINED_8_BIT_DATA_TYPE_2                  |
| 0x42  | USER_DEFINED_8_BIT_DATA_TYPE_3                  |
| 0x43  | USER_DEFINED_8_BIT_DATA_TYPE_4                  |
| 0x44  | USER_DEFINED_8_BIT_DATA_TYPE_5                  |
| 0x45  | USER_DEFINED_8_BIT_DATA_TYPE_6                  |
| 0x46  | USER_DEFINED_8_BIT_DATA_TYPE_7                  |
| 0x47  | USER_DEFINED_8_BIT_DATA_TYPE_8                  |
| 0x68  | RAW6 + EXP8                                     |
| 0x69  | RAW7 + EXP8                                     |
| 0x80  | USER_DEFINED_8_BIT_DATA_TYPE_1 + EXP8           |

| 0x2C6 | USER_DEFINED_8_BIT_DATA_TYPE_7 + DPCM10 + EXP16 |
| 0x2C7 | USER_DEFINED_8_BIT_DATA_TYPE_8 + DPCM10 + EXP16 |
| 0x329 | RAW7 + DPCM10 + VP                              |
| 0x32A | RAW8 + DPCM10 + VP                              |
| 0x340 | USER_DEFINED_8_BIT_DATA_TYPE_1 + DPCM10 + VP    |
| 0x341 | USER_DEFINED_8_BIT_DATA_TYPE_2 + DPCM10 + VP    |
| 0x342 | USER_DEFINED_8_BIT_DATA_TYPE_3 + DPCM10 + VP    |

**Table 6-60. Camera ISP CSI2 Receiver-Supported Data Types (continued)**

| Value | Data Type                                    |
|-------|----------------------------------------------|
| 0x343 | USER_DEFINED_8_BIT_DATA_TYPE_4 + DPCM10 + VP |
| 0x344 | USER_DEFINED_8_BIT_DATA_TYPE_5 + DPCM10 + VP |
| 0x345 | USER_DEFINED_8_BIT_DATA_TYPE_6 + DPCM10 + VP |
| 0x346 | USER_DEFINED_8_BIT_DATA_TYPE_7 + DPCM10 + VP |
| 0x347 | USER_DEFINED_8_BIT_DATA_TYPE_8 + DPCM10 + VP |
| 0x368 | RAW6 DPCM 12 + VP                            |
| 0x369 | RAW7 DPCM 12 + EXP 16                        |
| 0x36A | RAW8 DPCM 12 + EXP 16                        |
| 0x3A8 | RAW6 DPCM 12 + EXP 16                        |
| 0x3A9 | RAW7 DPCM 12 + VP                            |
| 0x3AA | RAW8 DPCM 12 + VP                            |

For each context, a [CSI2\\_CTX\\_CTRL2](#) register defines with which channel and data type the context is associated:

- The VIRTUAL\_ID field defines the associated virtual ID transported by the CSI2 protocol from the camera sensor.
- The FORMAT field defines the associated data type. The data type is a combination of the data type transported by the CSI2 protocol and the type of storage in memory. A given data type (RGB888) can be stored in memory in different ways (RGB888 or RGB888 + EXP32). Therefore, the FORMAT field also defines the way DMA stores data in memory.

For example, for the current context to capture a frame from virtual channel 2 and data type RAW12 with data expansion (RAW12 + EXP16), write the value 0x10AC (0x2 11 + 0xAC) in the 16 LSBs of the [CSI2\\_CTX\\_CTRL2](#) register.

#### 6.5.4.8 Camera ISP CSI2 Progressive and Interleaved Frame Configuration

The CSI2 receiver can treat both progressive and interlaced frames. There is no progressive or interleaved mode, but the [CSI2\\_CTX\\_CTRL1\[23:16\]](#) FEC\_NUMBER field controls the number of FECs before swapping to the other (ping or pong) buffer. Therefore, two modes are possible:

- FEC\_NUMBER = 1: This is equivalent to progressive mode. After a FEC on the context, the current buffer is switched (ping to pong or pong to ping). The image in the memory buffer consists of one transmitted frame.
- FEC\_NUMBER != 1: The current buffer is switched (ping to pong or pong to ping) after the FEC\_NUMBER FEC is received for the context. The image in the memory buffer consists of the FEC\_NUMBER transmitted frame.

For more information about how data is stored in memory through the DMA, see [Section 6.4.3.8, DMA Engine](#).

**NOTE:** If FEC\_NUMBER != 1, the camera sensor must send the line number information with the current line. Otherwise, the CSI2 receiver cannot calculate each line address.

#### 6.5.5 Programming the Timing CTRL Module

**NOTE:** All the following settings must be done before enabling the timing control module.

##### 6.5.5.1 Camera ISP Timing CTRL Timing Generator

The cam\_xclka clock frequency is set through the [TCTRL\\_CTRL\[4:0\]](#) DIVA bit field. The cam\_xclkb clock frequency is set through the [TCTRL\\_CTRL\[9:5\]](#) DIVB bit field. One can change the divisor values at any time.

For divisor values 0, 1, and 31, the divider is not enabled. For all other values:

- $\text{cam\_xclka} = \text{cam\_mclk}/\text{TCTRL\_CTRL}[4:0]$  DIVA
- $\text{cam\_xclkb} = \text{cam\_mclk}/\text{TCTRL\_CTRL}[9:5]$  DIVB

### 6.5.5.2 Camera ISP Timing CTRL Camera-Control Signal Generator

Enabling of the SHUTTER, PRESTROBE or STROBE signals generation and actives the counters:

- $\text{TCTRL\_CTRL}[21]$  SHUTEN = 1
- $\text{TCTRL\_CTRL}[22]$  PSTRBEN = 1
- $\text{TCTRL\_CTRL}[23]$  STRBEN = 1

Two configurations apply:

- The control signals are based on the vertical synchronization information coming from the camera module or from the externally generated `cam_global_reset` signal.
- The control signals are based on the internally generated `cam_global_reset`.

#### 6.5.5.2.1 Camera ISP Timing CTRL Vertical Synchro-Based Control-Signal Generation or Externally-Generated `cam_global_reset`

Before enabling the control-signal generation, the following registers must be set:

- Select the input that triggers the control signals. The trigger signal can come from the PARALLEL, CSI2A, CSI2C or CSI1/CCP2B interface, or the externally-generated `cam_global_reset` signal.
  - $\text{TCTRL\_CTRL}[28:27]$  INSEL
- The signal must be set to INPUT:
  - $\text{TCTRL\_CTRL}[31]$  GRESETDIR = 0x0
  - Writes to  $\text{TCTRL\_CTRL}[29]$  GRESETEN bit do not trigger the PRESTROBE, STROBE, and SHUTTER signals, and do not generate the `cam_global_reset` signal.
- The following bits are cleared automatically to 0 after the signal assertion:
  - $\text{TCTRL\_CTRL}[21]$  SHUTEN
  - $\text{TCTRL\_CTRL}[22]$  PSTRBEN
  - $\text{TCTRL\_CTRL}[23]$  STRBEN
- The following bits set the polarity of the SHUTTER, STROBE/PRESTROBE, and `cam_global_reset` signals. The signals can be active high or active low:
  - $\text{TCTRL\_CTRL}[24]$  SHUTPOL
  - $\text{TCTRL\_CTRL}[26]$  STRBPSTRBPOL
  - $\text{TCTRL\_CTRL}[30]$  GRESETPOL
- The following bit sets the clock divisor value, which generates the CNTCLK clock:
  - $\text{TCTRL\_CTRL}[18:10]$  DIVC

The clock is set by  $\text{CNTCLK} = \text{cam\_mclk}/\text{TCTRL\_CTRL}[18:10]$  DIVC. The possible values are 0 to 511. Setting DIVC = 0 disables the CNTCLK clock generation.

- The frame counters are set with (possible values are 0 to 63 frames):
  - $\text{TCTRL\_FRAME}[5:0]$  SHUT
  - $\text{TCTRL\_FRAME}[11:6]$  PSTRB
  - $\text{TCTRL\_FRAME}[17:12]$  STRB

---

**NOTE:** If the value is 0, the timing control module does not delay any frame in input.

---

- The delay counters are set with:
  - $\text{TCTRL\_SHUT\_DELAY}$
  - $\text{TCTRL\_PSTRB\_DELAY}$

- [TCTRL\\_STRB\\_DELAY](#)

The possible values are 0 to  $2^{25}$  - 1 cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{25} - 1) \times 2.366 \text{ s} = 79 \text{ s}$  ([TCTRL\\_CTRL\[18:10\]](#) DIVC = 511).

- The signal durations are set with:

- [TCTRL\\_SHUT\\_LENGTH](#)

- [TCTRL\\_PSTRB\\_LENGTH](#)

- [TCTRL\\_STRB\\_LENGTH](#)

The possible values are 0 to  $2^{24}$  - 1 cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{24} - 1) \times 2.366 \text{ s} = 39.69 \text{ s}$  ([TCTRL\\_CTRL\[18:10\]](#) DIVC = 511).

#### **6.5.5.2.2 Camera ISP Timing CTRL Internally-Generated cam\_global\_reset-Based Control-Signal Generation**

Before enabling the cam\_global\_reset control-signal generation by writing [TCTRL\\_CTRL\[29\]](#) GRESETEN = 1, the following registers must be set:

---

**NOTE:** Setting [TCTRL\\_CTRL\[21\]](#) SHUTEN, [TCTRL\\_CTRL\[22\]](#) PSTRBEN, [TCTRL\\_CTRL\[23\]](#) STRBEN, and [TCTRL\\_CTRL\[29\]](#) GRESETEN to 1 simultaneously leads to unpredictable behavior. The [TCTRL\\_CTRL\[21\]](#) SHUTEN, [TCTRL\\_CTRL\[22\]](#) PSTRBEN, [TCTRL\\_CTRL\[23\]](#) STRBEN must be set before [TCTRL\\_CTRL\[29\]](#) GRESETEN is enabled.

---

- The signal must be set to OUTPUT:
  - [TCTRL\\_CTRL\[31\]](#) GRESETDIR = 0x1
  - Vertical synchronization events do not trigger the PRESTROBE, STROBE, and SHUTTER signals.
- The following bits are cleared automatically to 0 after the signal assertion:
  - [TCTRL\\_CTRL\[21\]](#) SHUTEN
  - [TCTRL\\_CTRL\[22\]](#) PSTRBEN
  - [TCTRL\\_CTRL\[23\]](#) STRBEN
  - [TCTRL\\_CTRL\[29\]](#) GRESETEN
- The following bits set the polarity of the SHUTTER, STROBE/PRESTROBE, and cam\_global\_reset signals. The signals can be active high or active low:
  - [TCTRL\\_CTRL\[24\]](#) SHUTPOL
  - [TCTRL\\_CTRL\[26\]](#) STRBPSTRBPOL
  - [TCTRL\\_CTRL\[30\]](#) GRESETPOL
- The following bit sets the clock divisor value, which generates the CNTCLK clock:
  - [TCTRL\\_CTRL\[18:10\]](#) DIVC

The clock is set by CNTCLK = cam\_mclk/[TCTRL\\_CTRL\[18:10\]](#) DIVC. The possible values are 0 to 511. Setting DIVC = 0 disables the CNTCLK clock generation.
- The frame counters bit fields are ignored:
  - [TCTRL\\_FRAME\[5:0\]](#) SHUT
  - [TCTRL\\_FRAME\[11:6\]](#) PSTRB
  - [TCTRL\\_FRAME\[17:12\]](#) STRB
- The delay counters are set with:
  - [TCTRL\\_SHUT\\_DELAY](#)
  - [TCTRL\\_PSTRB\\_DELAY](#)
  - [TCTRL\\_STRB\\_DELAY](#)

The possible values are 0 to 225 - 1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{25} - 1) \times 2.366 \text{ s} = 79 \text{ s}$  ([TCTRL\\_CTRL\[18:10\]](#) DIVC = 511).
- The signal durations are set with:
  - [TCTRL\\_SHUT\\_LENGTH](#)

- [TCTRL\\_PSTRB\\_LENGTH](#)
- [TCTRL\\_STRB\\_LENGTH](#)

The possible values are 0 to  $2^{24} - 1$  cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{24} - 1) \times 2.366 \text{ s} = 39.69 \text{ s}$  ([TCTRL\\_CTRL\[18:11\]](#) DIVC = 511).

- The cam\_global\_reset assertion time is set by [TCTRL\\_GRESET\\_LENGTH](#). The possible values are 0 to  $2^{24} - 1$  cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{24} - 1) \times 2.366 \text{ s} = 39.69 \text{ s}$  ([TCTRL\\_CTRL\[18:11\]](#) DIVC = 511).

#### 6.5.5.2.3 Camera ISP Timing CTRL STROBE and PRESTROBE Signal Generation for Red-Eye Removal

The STROBE and PRESTROBE signal generation enables a strobe flash for red eye removal. The process is shown in [Figure 6-110](#). The dotted line corresponds to known timings from which the delay counters start decreasing: cam\_global\_reset event.

**Figure 6-110. cam\_strobe Signal-Generation for Red-Eye Removal**

- t1: Set by the [TCTRL\\_PSTRB\\_DELAY](#) register
- t2: set by the [TCTRL\\_PSTRB\\_LENGTH](#) register
- t5: set by the [TCTRL\\_PSTRB\\_REPEAT\[24:0\]](#) DELAY bit field. The number of times the pulse is repeated is controlled by the [TCTRL\\_PSTRB\\_REPEAT\[31:25\]](#) COUNTER register.

In the former example, [TCTRL\\_PSTRB\\_REPEAT\[31:25\]](#) COUNTER = 2.

- The possible delay values are 0 to  $2^{25} - 1$  cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{25} - 1) \times 2.366 \text{ s} = 79 \text{ s}$  ([TCTRL\\_CTRL\[18:11\]](#) DIVC = 511).
- The possible count values are 0 to 127 additional pulses.
- t3: Set by the [TCTRL\\_STRB\\_DELAY](#) register
- t4: Set by the [TCTRL\\_STRB\\_LENGTH](#) register

#### 6.5.6 Programming the CCDC

This section discusses issues related to the software control of the CCDC. It lists which registers are required to be programmed in different modes, and describes how to enable and disable the CCDC, how to check the status of the CCDC, the different register access types, and programming constraints.

##### 6.5.6.1 Camera ISP CCDC Hardware Setup/Initialization

This section discusses the configuration of the CCDC required before image processing can begin.

###### 6.5.6.1.1 Camera ISP CCDC Reset Behavior

On hardware reset of the camera ISP, all registers in the CCDC are reset to their reset values.

### **6.5.6.1.2 Camera ISP CCDC Register Setup**

Before enabling the CCDC, the hardware must be correctly configured through register writes. Table 6-61 identifies the register parameters that must be programmed before enabling the CCDC.

**Table 6-61. Camera ISP CCDC Required Configuration Parameters**

| Function                          | Configuration Required                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

#### 6.5.6.1.3 Camera ISP CCDC Pixel Selection (Framing) Register Dependencies

There are three locations in the data flow where the valid frame data can be defined:

- Data formatter input pixel selection
- Video port output pixel selection
- Output formatter pixel selection

Care must be taken to ensure that the frame definitions correspond to the output of the upstream frame definitions. When the video port is enabled, `CCDC_VP_OUT[30:17]` VERT\_NUM must be less than `CCDC_FMT_VERT[12:0]` FMTLNV.

Two data paths through the CCDC affect the programming of the pixel-selection registers, depending on the value of the `CCDC_SYN_MODE[18]` VP2SDR bit:

- VP2SDR = 0: The input data bypasses the data formatter/video port. In this case, only the memory output frame parameters apply. This data path is represented by the white arrow in [Figure 6-111](#).
- VP2SDR = 1: The input data passes through the data formatter/video port. In this case, both data formatter frame definitions apply to the video-port output, and all three frame definitions apply to the memory output. This data path is represented by the green shaded arrow in [Figure 6-111](#).

**Figure 6-111. Camera ISP CCDC Dependencies Among Framing Settings in Data Flow**

### 6.5.6.2 Camera ISP CCDC Enable/Disable Hardware

All required registers mentioned in the previous section must be programmed before setting the [CCDC\\_PCR\[0\]](#) ENABLE bit.

The CCDC always operates in continuous mode. In other words, after enabling the CCDC, it processes sequential frames until the ENABLE bit is cleared by software. When this happens, the frame being processed completes before the CCDC is disabled.

When the CCDC is in master mode (HS/VS signals set to outputs), fetching and processing of the frame begin immediately on setting the [CCDC\\_PCR\[0\]](#) ENABLE bit.

When the CCDC is in slave mode (HS/VS signals set to inputs), processing of the frame depends on the input timing of the external sensor/decoder. To ensure that data from the external device is not missed, the CCDC must be enabled before data transmission from the external device. In this way, the CCDC waits for data from the external device.

On setting the [CCDC\\_FPC\[15\]](#) FPCEN bit, the CCDC begins to fetch and buffer the faulty-pixel table from memory. If faulty-pixel correction is used, the [CCDC\\_FPC\[15\]](#) FPCEN bit must be set before the [CCDC\\_PCR\[0\]](#) ENABLE bit, but after the faulty-pixel table is placed in memory and the [CCDC\\_FPC\[14:0\]](#) FPNUM and [CCDC\\_FPC\\_ADDR](#) registers are set.

### 6.5.6.3 Camera ISP CCDC Events and Status Checking

The CCDC can generate three different interrupts: CCDC\_VD0\_IRQ, CCDC\_VD1\_IRQ, and CCDC\_VD2\_IRQ.

The [CCDC\\_SYN\\_MODE\[16\]](#) VDHDEN bit must be enabled to receive any of the CCDC CCDC\_VDx\_IRQ interrupts.

#### 6.5.6.3.1 Camera ISP CCDC Interrupts

The CCDC module has three programmable events: CCDC\_VD0\_IRQ, CCDC\_VD1\_IRQ, and CCDC\_VD2\_IRQ, and one error event CCDC\_ERR\_IRQ. Event generation is described in [Section 6.5.6.3.2, CCDC\\_VD0\\_IRQ and CCDC\\_VD1\\_IRQ Interrupts](#), and [Section 6.5.6.3.3, CCDC\\_VD2\\_IRQ Interrupt](#).

CCDC module events can be mapped to the ARM or the DSP:

- The CCDC\_VD0\_IRQ, CCDC\_VD1\_IRQ, CCDC\_VD2\_IRQ, and CCDC\_ERR\_IRQ bits in the [ISP IRQ0ENABLE](#) register control whether the CCDC module events trigger an interrupt to the ARM. The [ISP IRQ0STATUS](#) register indicates which event(s) triggered the interrupt. An event is cleared by writing a 1 in its corresponding bit in the [ISP IRQ0STATUS](#) register. To clear the CCDC\_ERR\_IRQ interrupt, clear the [CCDC\\_FPC\[16\]](#) FPERR bit before clearing the [ISP IRQ0STATUS\[11\]](#) CCDC\_ERR\_IRQ bit.
- The CCDC\_VD0\_IRQ, CCDC\_VD1\_IRQ, CCDC\_VD2\_IRQ, and CCDC\_ERR\_IRQ bits in the [ISP IRQ1ENABLE](#) register control whether the CCDC module events trigger an interrupt to the DSP. The [ISP IRQ1STATUS](#) register indicates which event(s) triggered the interrupt. An event is cleared by writing a 1 in its corresponding bit in the [ISP IRQ1STATUS](#) register. To clear the CCDC\_ERR\_IRQ interrupt, clear the [CCDC\\_FPC\[16\]](#) FPERR bit before clearing the [ISP IRQ1STATUS\[11\]](#) CCDC\_ERR\_IRQ bit.

#### 6.5.6.3.2 Camera ISP CCDC CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ Interrupts

As shown in [Figure 6-112](#), the CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ interrupts occur relative to the VS pulse. The trigger timing is selected by using the [CCDC\\_SYN\\_MODE\[2\]](#) VDPOL setting. CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ occur after receiving the number of horizontal lines (HS pulse signals) set in the [CCDC\\_VDINT\[30:16\]](#) VDINT0 and [CCDC\\_VDINT\[14:0\]](#) VDINT1 register fields, respectively.

---

**NOTE:** In the case of BT.656 input mode, there is VS at the beginning of each field. Therefore, there are two interrupts for each frame (one for each field).

---

If **CCDC\_SYN\_MODE[2]** VDPOL is 0, the CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ HS counters begin counting HS pulses from the rising edge of the external VS, as shown in [Figure 6-112](#).

**Figure 6-112. Camera ISP CCDC CCDC\_VD0\_IRQ/CCDC\_VD1\_IRQ Interrupt Behavior When VDPOL = 0**

If **CCDC\_SYN\_MODE[2]** VDPOL is 1, the CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ HS counters begin counting HS pulses from the falling edge of the external VS.

**Figure 6-113. Camera ISP CCDC CCDC\_VD0\_IRQ/CCDC\_VD1\_IRQ Interrupt Behavior When VDPOL = 1**

#### 6.5.6.3.3 Camera ISP CCDC CCDC\_VD2\_IRQ Interrupt

In addition to the CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ interrupts, the CCDC has an interrupt called CCDC\_VD2\_IRQ. This interrupt always occurs at the falling edge of the WEN signal (through external pin). There are no registers in the CCDC module to configure this interrupt (see [Figure 6-114](#)).

**Figure 6-114. Camera ISP CCDC CCDC\_VD2\_IRQ Interrupt Behavior**

#### 6.5.6.3.4 Camera ISP CCDC Status Checking

The **CCDC\_PCR[1]** BUSY status bit is set when the start of frame occurs (if the **CCDC\_PCR[0]** ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The **CCDC\_PCR[1]** BUSY status bit may be polled to determine end-of-frame status.

The **CCDC\_FPC[16]** FPERR status bit is set when faulty-pixel data fetched from memory arrives late. This bit can be reset by writing a 1 to the bit.

#### 6.5.6.4 Camera ISP CCDC Register Accessibility During Frame Processing

There are three types of register access in the CCDC:

- Shadowed registers: In the CCDC, two register fields are shadowed in different ways. Shadowed registers can be read and written at any time, but the written values take effect (are latched) only at certain times, based on some event. Reads return the most recent write, even though the settings are not used until the specific event occurs. The shadowed registers are:
  - **CCDC\_PCR[0]** ENABLE
    - Written values take effect only at the start of a frame event (rising edge of VD if **CCDC\_SYN\_MODE[2]** VDPOL is positive, or falling edge of VD if **CCDC\_SYN\_MODE[2]** VDPOL is negative).
  - **CCDC\_SDR\_ADDR**

- When **CCDC\_CFG[15]** VDLC is set to 0, written values take effect only at the start of a frame event (rising edge of VD if **CCDC\_SYN\_MODE[2]** VDPOL is positive, or falling edge of VD if **CCDC\_SYN\_MODE[2]** VDPOL is negative). When **CCDC\_CFG[15]** VDLC is set to 1, written values take effect only at the start of the frame being output to memory (when the input has reached the **CCDC\_HORZ\_INFO[30:16]** SPH pixel of the **CCDC\_VERT\_START[30:16]** SLV0 or **CCDC\_VERT\_START[14:0]** SLV1 line of each field).
- Busy-writable registers: These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.  
All register fields in the CCDC not formerly listed as shadowed or below as optionally shadowed/busy-writable are busy-writable registers.
- Optionally Shadowed/Busy-Writable registers: All registers/fields listed below can be set as either shadow registers or busy-writable registers:
  - When **CCDC\_CFG[15]** VDLC is 0, these registers are shadowed.
  - When **CCDC\_CFG[15]** VDLC is 1, these registers are busy-writable.

**NOTE:** **CCDC\_CFG[15]** VDLC must be set to 1 by software if the CCDC is to be used; therefore, these registers are busy-writable. If **CCDC\_CFG[15]** VDLC remains set to 0 (default), indeterminate results may occur for ANY register access in the CCDC, not just those listed in the following.

- Optionally shadowed or busy-writable registers
  - **CCDC\_SYN\_MODE[19]** SDR2RSZ
  - **CCDC\_SYN\_MODE[18]** VP2SDR
  - **CCDC\_SYN\_MODE[16]** VDHDEN
  - **CCDC\_SYN\_MODE[17]** WEN
  - **CCDC\_SYN\_MODE[14]** LPF
  - **CCDC\_HD\_VD\_WID**
  - **CCDC\_PIX\_LINES**
  - **CCDC\_HORZ\_INFO**
  - **CCDC\_VERT\_START**
  - **CCDC\_VERT\_LINES**
  - **CCDC\_CULLING**
  - **CCDC\_HSIZE\_OFF**
  - **CCDC\_SDOFST**
  - **CCDC\_CLAMP[31]** CLAMPEN
  - **CCDC\_FMTCFG[0]** FMTEN
  - **CCDC\_LSC\_CONFIG**
  - **CCDC\_LSC\_INITIAL**
  - **CCDC\_LSC\_TABLE\_BASE**
  - **CCDC\_LSC\_TABLE\_OFFSET**

#### 6.5.6.5 Camera ISP CCDC Interframe Operations

Between frames, it may be necessary to enable/disable functions or modify memory pointers. Because the **CCDC\_PCR** register and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

## 6.5.6.6 Camera ISP CCDC Operations

### 6.5.6.6.1 Camera ISP CCDC Image-Sensor Configuration

#### 6.5.6.6.1.1 Camera ISP CCDC Input-Mode Selection

The CCDC module supports two modes: SYNC mode and ITU-R BT.656 mode. Specific settings correspond to each mode.

- SYNC mode:
  - In this mode, the input data can be either raw data or YCbCr data. Setting `CCDC_SYN_MODE.INPMODE` = 0 selects raw data, and `CCDC_SYN_MODE[13:12]` INPMODE = 1 or 2 selects YCbCr data on 16 or 8 bits. If `CCDC_SYN_MODE[13:12]` INPMODE = 0, the `cam_d` signal width is selected through `CCDC_SYN_MODE[10:8]` DATSIZ: the possible values are 8, 10, 11, and 12 bits.
  - If `CCDC_SYN_MODE[13:12]` INPMODE = 1, the `cam_d` signal width is 8 bits, but the internal CCDC module data path is configured to 16 bits. It is mandatory to enable the 8- to 16-bit bridge by setting `ISP_CTRL[3:2]` PAR\_BRIDGE = 2 or 3. The `ISP_CTRL[3:2]` PAR\_BRIDGE bit also controls how the 8-bit data is mapped onto the 16-bit data.
  - The value set in `CCDC_SYN_MODE[10:8]` DATSIZ does not matter. The position of the Y component can be set with the `CCDC_CFG[11]` Y8POS bit.
  - If `CCDC_SYN_MODE[13:12]` INPMODE = 2, the `cam_d` signal width is 8 bits. The value set in `CCDC_SYN_MODE[10:8]` DATSIZ does not matter. The position of the Y component can be set with the `CCDC_CFG[11]` Y8POS bit.
  - The internal timing generator must be enabled with `CCDC_SYN_MODE[16]` VDHDEN = 1.
- ITU mode:
  - In this mode, the data follows the protocol set by the ITU-R BT.656 protocol. To select it, set `CCDC_REC656IF[0]` R656ON = 1. When this mode is selected, the values set in `CCDC_SYN_MODE[13:12]` INPMODE and `CCDC_SYN_MODE[10:8]` DATSIZ do not matter.
  - To select the 8-bit or 10-bit protocol, set the `CCDC_CFG[5]` BW656 bit field. Data line `cam_d` [7:0] are used for 8-bit YCbCr and `cam_d`[9:0] are used for 10-bit YCbCr.
  - FVH error correction is enabled by setting `CCDC_REC656IF[1]` ECCFVH = 1.
  - The internal timing generator must be enabled with `CCDC_SYN_MODE[16]` VDHDEN = 1.

#### 6.5.6.6.1.2 Camera ISP CCDC Timing Generator and Frame Settings

The polarities of the `cam_hs`, `cam_vs`, and `cam_fld` signals are controlled by the `CCDC_SYN_MODE[3]` HDPOL, `CCDC_SYN_MODE[2]` VDPOL, and `CCDC_SYN_MODE[4]` FLDPOL bit fields. The polarities can be positive or negative.

The pixel data is presented on `cam_d` one pixel for every `cam_pclk` rising edge or falling edge. It is controlled with the `ISP_CTRL[4]` PAR\_CLK\_POL bit.

The `CCDC_SYN_MODE[7]` FLDMODE bit fields set the image-sensor type to progressive or interlaced mode. When the sensor is interlaced, the `CCDC_SYN_MODE[15]` FLDSTAT status bit indicates whether the current frame is odd or even.

The polarity of the `cam_d` signal can also be controlled with the `CCDC_SYN_MODE[6]` DATAPOL bit field. The polarity can be normal mode or ones complement mode.

Furthermore, the directions of the `cam_fld` and `cam_hs/cam_vs` signals are controlled by the `CCDC_SYN_MODE[1]` FLDOOUT and `CCDC_SYN_MODE[0]` VDHDOOUT bits. If `CCDC_SYN_MODE[0]` VDHDOOUT is set as an output, the `CCDC_PIX_LINES` register controls the length of the `cam_hs` and `cam_vs` signals.

If `CCDC_SYN_MODE[0]` VDHDOOUT = 1:

- The HS sync pulse width is given by `CCDC_HD_VD_WID[27:16]` HDW. The VS sync pulse width is given by `CCDC_HD_VD_WID[11:0]` VDW.

- The HS period is given by `CCDC_PIX_LINES[31:16]` PPLN. The VS period is given by `CCDC_PIX_LINES[15:0]` HLPRF x 2.

Figure 6-115 shows the HS/VS sync pulse output timings.

**Figure 6-115. Camera ISP CCDC HS/VS Sync Pulse Output Timings**

camisp-117

#### 6.5.6.6.1.3 Camera ISP CCDC Mosaic Filter Settings

The CCDC module supports image sensors with R, G, and B primary color mosaic filters and Ye, Cy, Mg, and G complementary color mosaic filters. The mosaic filter layout pattern is controlled by the `CCDC_COLPTN` register. Each bit field in this register controls the color associated to one pixel in a 4x4 region area. The 4x4 area repeats horizontally and vertically.

Figure 6-116 shows configuration examples of the `CCDC_COLPTN` register. It is assumed that CP0LPC0 is the first pixel output and CP3LPC3 is the last pixel output during frame readout.

**Figure 6-116. Camera ISP CCDC Mosaic Filter - CCDC\_COLPTN Bit Field Settings**

### 6.5.6.6.2 Camera ISP CCDC Image-Signal Processing

#### 6.5.6.6.2.1 Camera ISP CCDC Digital Clamp

Digital clamp is enabled only if optical black clamping is disabled: [CCDC\\_CLAMP\[31\]](#) CLAMPEN = 0. The digital clamp DC value to be subtracted from the raw image data ([CCDC\\_SYN\\_MODE\[13:12\]](#) INPMOD = 0) or from the luminance ([CCDC\\_SYN\\_MODE\[13:12\]](#) INPMOD = 0 or [CCDC\\_REC656IF\[0\]](#) R656ON = 1) is set with the [CCDC\\_DCSUB](#) register. The DC value can range from 0 to 212-1. The reset value is 0.

#### 6.5.6.6.2.2 Camera ISP CCDC Optical Black Clamping

Optical black clamping is enabled by setting [CCDC\\_CLAMP\[31\]](#) CLAMPEN to 1. When enabled, an average of black-pixel samples is computed over a window. If the height of the window is 2N, the average value multiplied by a programmable gain factor is subtracted from the raw image data for the following 2N lines. Every 2N lines, a new average value is computed. For the first 2N lines, 0 is subtracted.

The size of the window and horizontal position are controlled by the [CCDC\\_CLAMP](#) register. The vertical position of the window is set to line 0 and cannot be modified:

- [CCDC\\_CLAMP\[30:28\]](#) OBSLEN sets the horizontal size of the window (1, 2, 4 or 8 pixels).
- [CCDC\\_CLAMP\[27:25\]](#) OBSLN sets the vertical size of the window (2N = 1, 2, 4 or 8 lines).
- [CCDC\\_CLAMP\[24:10\]](#) OBST sets the horizontal start position of the upper-left corner of the window. It is specified from the start of the HS sync pulse in pixel clocks.

The gain factor is set by the [CCDC\\_CLAMP\[4:0\]](#) OBGAIN bit field. Its fixed-point representation is U5Q4; the range is 0 to 1.9375. The gain factor reset value is 1.

If optical-black clamping is disabled, digital clamp is enabled.

#### 6.5.6.6.2.3 Camera ISP CCDC Black Compensation

Black compensation applies an offset to the raw image data. The offset is applied according to the phase and color for each phase. The black compensation offsets are controlled by the [CCDC\\_BLKCMP](#) register. All offsets are coded in S8Q0 representation (two's complement); the range is -128 to +127.

#### 6.5.6.6.2.4 Camera ISP CCDC Faulty-Pixel Correction

Faulty-pixel correction is enabled by setting the [CCDC\\_FPC\[15\]](#) FPCEN bit to 1. Before activating faulty-pixel correction, set the number of faulty pixels to be corrected in a frame with the [CCDC\\_FPC\[14:0\]](#) FPNUM bit field, set the faulty-pixel LUT in memory, and set the [CCDC\\_FPC\\_ADDR](#) register to the LUT address. The address should be aligned to a 64-bit byte boundary; the 6 LSBs are ignored. Reading the register always shows the 6 LSBs as 0.

If the CCDC module cannot fetch the required faulty-pixel entry in time, an error is set in the [CCDC\\_FPC\[16\]](#) FPERR bit. After the bit is set, no more faulty pixels are corrected in the frame. The bit is automatically cleared on the end of the frame and the feature reenabled for the following frame.

#### 6.5.6.6.2.5 Camera ISP CCDC Data Formatter

The data formatter transforms movie mode readout patterns into Bayer readout patterns. It is enabled by setting [CCDC\\_FMTCFG\[0\]](#) FMTEN to 1.

The [CCDC\\_FMT\\_HORZ](#) and [CCDC\\_FMT\\_VERT](#) registers set a clip window at the input of the data reformatter.

The data formatter converts a single line of movie mode sensor into multiple Bayer lines; it is capable of transforming 1 input line into 1, 2, 3, or 4 output lines. The number of lines generated from one input line is set by the [CCDC\\_FMTCFG\[3:2\]](#) LNUM bit field. The following limitations apply:

- The maximum number of pixels that can be supported in an output line if the input line is transformed into 1 output line is 4x1376 (1376 is the limit of the line memory).
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 2 output lines is 2x1376.
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 3 output lines is 1376.
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 4 output lines is 1376.

The data reformatter gets its flexibility from up to 8 different addresses and a program that can contain up to 16 entries each for the odd and even lines. The program length for even fields is set with the [CCDC\\_FMTCFG\[11:8\]](#) PLEN\_EVEN bit field. The program length for odd fields is set with the [CCDC\\_FMTCFG\[7:4\]](#) PLEN\_ODD bit fields. Each entry refers to one of the 8 addresses and supports autoincrement and autodecrement.

- The 8 addresses are controlled by the [CCDC\\_FMT\\_ADDRx](#) registers ( $x = 0$  to 7).
- The 16 program entries for even lines are controlled by the [CCDC\\_PRGEVEN0](#) and [CCDC\\_PRGEVEN1](#) registers. The 16 program entries for odd lines are controlled by the [CCDC\\_PRGODD0](#) and [CCDC\\_PRGODD1](#) registers.

Modulo addressing is used to access the program entries. Even input lines use the even program and odd input lines use the odd program. Each new pixel in a line uses one program entry.

The [CCDC\\_VP\\_OUT](#) register sets the frame size at the output of the video port.

#### Example 6-2. Conventional readout pattern: 1 input line = 1 output line

The following input-to-output mapping (see [Table 6-63](#)) corresponds to a conventional readout pattern. One input line corresponds to 1 output line; the output can be as large as 4x1376 pixels.

**Table 6-63. Camera ISP CCDC Conventional Readout Pattern 1 to 1**

| Input    | Pixels order in input line  |   |   |   |       |      |      |      |      |  |
|----------|-----------------------------|---|---|---|-------|------|------|------|------|--|
| Output   | Pixels order in output line |   |   |   |       |      |      |      |      |  |
| Line [i] | 0                           | 1 | 2 | 3 | [...] | 5500 | 5501 | 5502 | 5503 |  |

To obtain this mapping between the input and output pixels, the following settings apply:

- CCDC\_FMTCFG [3:2] LNUM = 0 Converts to 1 line
- CCDC\_FMTCFG [11:8] PLEN\_EVEN = 0 1 program entry
- CCDC\_FMTCFG [7:4] PLEN\_ODD = 0 1 program entry
- CCDC\_FMT\_ADDR\_i [25:24] LINE (i = 0) = 0 Init ADDR0 pointer to 0th line
- CCDC\_FMT\_ADDR\_i [12:0] INIT (i = 0) = 0 Init ADDR0 index to 0th pixel
- CCDC\_PRGEVEN0 [3:0] EVEN0 = 0 Even prog entry 0: ADDR0++
- CCDC\_PRGODDO [3:0] ODD0 = 0 Odd prog entry 0: ADDR0++
- CCDC\_VP\_OUT [3:0] HORZ\_ST = 0 Horizontal start
- CCDC\_VP\_OUT [16:4] HORZ\_NUM = 0 Horizontal size

The program for even and odd lines is executed as follows. Because there is only one program entry, this instruction is executed repeatedly.

```
ADDR0= (0, 0)
While not end_of_line
{
 Write incoming pixel to ADDR0
 ADDR0+=(1, 0)
}
```

#### **Example 6-3. Dual readout pattern: 1 input line = 1 output line**

The following input-to-output mapping (see [Table 6-64](#)) corresponds to a conventional dual readout pattern. One input line corresponds to 1 output line; the output can be as large as 4x1376 pixels.

**Table 6-64. Camera ISP CCDC Dual Readout Pattern 1 to 1**

| Input    | Pixels order in input line  |   |   |   |       |      |      |      |      |
|----------|-----------------------------|---|---|---|-------|------|------|------|------|
| Output   | Pixels order in output line |   |   |   |       |      |      |      |      |
| Line [i] | 0                           | 1 | 2 | 3 | [...] | 4092 | 4093 | 4094 | 4095 |
| Line [i] | 0                           | 2 | 4 | 6 | [...] | 7    | 5    | 3    | 1    |

To obtain this mapping between the input and output pixels, the following settings apply:

- CCDC\_FMTCFG [3:2] LNUM = 0 Converts to 1 line
- CCDC\_FMTCFG [11:8] PLEN\_EVEN = 1 2 program entry
- CCDC\_FMTCFG [7:4] PLEN\_ODD = 1 2 program entry
- CCDC\_FMT\_ADDR\_i [25:24] LINE (i = 0) = 0 Init ADDR0 pointer to 0th line
- CCDC\_FMT\_ADDR\_i [12:0] INIT (i = 0) = 0 Init ADDR0 index to 0th pixel
- CCDC\_FMT\_ADDR\_i [25:24] LINE (i = 1) = 0 Init ADDR1 pointer to 0th line
- CCDC\_FMT\_ADDR\_i [12:0] INIT (i = 1) = 4095 Init ADDR1 index to 4095th pixel
- CCDC\_PRGEVEN0 [3:0] EVEN0 = 0 Even prog entry 0: ADDR0++
- CCDC\_PRGEVEN0 [7:4] EVEN1 = 3 Even prog entry 1: ADDR1--
- CCDC\_PRGODDO [3:0] ODD0 = 0 Even prog entry 0: ADDR0++
- CCDC\_PRGODDO [7:4] ODD1 = 3 Even prog entry 1: ADDR1--
- CCDC\_VP\_OUT [3:0] HORZ\_ST = 0 Horizontal start
- CCDC\_VP\_OUT [16:4] HORZ\_NUM = 0 Horizontal size

```

ADDR0=(0,0)
ADDR1=(4095,0)
While not end_of_line
{
 Write incoming pixel to ADDR0
 ADDR0+=(1,0)
 Write incoming pixel to ADDR1
 ADDR1 -=(1,0)
}

```

**Example 6-4. Dual readout pattern: 1 input line = 3 output line**

The following input-to-output mapping (see [Table 6-65](#)) corresponds to a complex pattern. One input line corresponds to 3 output lines; the output can be as large as 1376 pixels.

**Table 6-65. Camera ISP CCDC Dual Readout Pattern 1 to 3**

| Input         | Pixels order in input line  |    |    |       |       |    |    |    |   |
|---------------|-----------------------------|----|----|-------|-------|----|----|----|---|
| Line [i]      | 0                           | 1  | 2  | 3     | 4     | 5  | 6  | 7  | 8 |
|               | 9                           | 10 | 11 | [...] |       |    |    |    |   |
| Output        | Pixels order in output line |    |    |       |       |    |    |    |   |
| Line [3i]     |                             |    | 0  | 6     | [...] | 23 | 17 | 11 | 5 |
| Line [3i + 1] |                             | 2  | 8  | 14    | [...] | 15 | 9  | 3  |   |
| Line [3i + 2] | 4                           | 10 | 16 | 22    | [...] | 7  | 1  |    |   |

To obtain this mapping between the input and output pixels, the following settings apply:

- CCDC\_FMTCFG [3:2] LNUM = 2 Converts to 3 lines
- CCDC\_FMTCFG [11:8] PLEN\_EVEN = 5 6 program entries
- CCDC\_FMTCFG [7:4] PLEN\_ODD = 5 6 program entries
- CCDC\_FMT\_ADDR\_i [25:24] LINE (i = 0) = 0 Init ADDR0 pointer to 0th line
- CCDC\_FMT\_ADDR\_i [12:0] INIT (i = 0) = 2 Init ADDR0 index to 2nd pixel
- CCDC\_FMT\_ADDR\_i [25:24] LINE (i = 1) = 2 Init ADDR1 pointer to 2nd line
- CCDC\_FMT\_ADDR\_i [12:0] INIT (i = 1) = 855 Init ADDR1 index to 855th pixel
- CCDC\_FMT\_ADDR\_i [25:24] LINE (i = 2) = 1 Init ADDR2 pointer to first line
- CCDC\_FMT\_ADDR\_i [12:0] INIT (i = 2) = 1 Init ADDR2 index to first pixel
- CCDC\_FMT\_ADDR\_i [25:24] LINE (i = 3) = 1 Init ADDR3 pointer to first line
- CCDC\_FMT\_ADDR\_i [12:0] INIT (i = 3) = 856 Init ADDR3 index to 856th pixel
- CCDC\_FMT\_ADDR\_i [25:24] LINE (i = 4) = 2 Init ADDR4 pointer to second line
- CCDC\_FMT\_ADDR\_i [12:0] INIT (i = 4) = 0 Init ADDR4 index to 0th pixel
- CCDC\_FMT\_ADDR\_i [25:24] LINE (i = 5) = 0 Init ADDR5 pointer to 0th line
- CCDC\_FMT\_ADDR\_i [12:0] INIT (i = 5) = 857 Init ADDR5 index to 857th pixel
- CCDC\_PRGEVEN0 [3:0] EVEN0 = 0 Even prog entry 0: ADDR0++
- CCDC\_PRGEVEN0 [7:4] EVEN1 = 3 Even prog entry 1: ADDR1--
- CCDC\_PRGEVEN0 [11:8] EVEN2 = 4 Even prog entry 2: ADDR2++
- CCDC\_PRGEVEN0 [15:12] EVEN3 = 7 Even prog entry 3: ADDR3--
- CCDC\_PRGEVEN0 [19:16] EVEN4 = 8 Even prog entry 4: ADDR4++
- CCDC\_PRGEVEN0 [23:20] EVEN5 = 11 Even prog entry 4: ADDR5--
- CCDC\_PRGODDO [3:0] ODD0 = 0 Even prog entry 0: ADDR0++
- CCDC\_PRGODDO [7:4] ODD1 = 3 Even prog entry 1: ADDR1--
- CCDC\_PRGODDO [11:8] ODD2 = 4 Even prog entry 2: ADDR2++

|                               |                                               |
|-------------------------------|-----------------------------------------------|

 Write incoming pixel to ADDR3
 ADDR3 -= (1, 0)
 Write incoming pixel to ADDR4
 ADDR4 += (1, 0)
 Write incoming pixel to ADDR5
 ADDR5 -= (1, 0)
}

```

### Video Port

The 10-bit video-port output is enabled with [CCDC\\_FMTCFG\[15\]](#) VPEN = 1. Because the input data can be up to 12 bits, one must select which 10 bits are selected with [CCDC\\_FMTCFG\[14:12\]](#) VPIN.

The output of the video port goes to the Preview module. At the output of the video port, the data rate is resynchronized; the [CCDC\\_FMTCFG\[21:16\]](#) VPIF\_FRQ bit field selects the video-output data rate as: L3 speed/([CCDC\\_FMTCFG\[21:16\]](#) VPIF\_FRQ + 2) (from L3 speed/ 2 MHz to L3 speed/8 MHz). If [CCDC\\_FMTCFG\[21:16\]](#) VPIF\_FRQ frequency is set too low compared to the input pixel clock, overflow can occur.

#### 6.5.6.6.2.6 Camera ISP CCDC Output Formatter

##### 6.5.6.6.2.6.1 Camera ISP CCDC Low-Pass Filter

The low-pass filter is enabled with the [CCDC\\_SYN\\_MODE\[14\]](#) LPF bit. When enabled, two pixels each in the left and right edges of each line are cropped from the output.

##### 6.5.6.6.2.6.2 Camera ISP CCDC A-Law Compression

A-Law compression is enabled by setting [CCDC\\_ALAW](#) [3] CCDTBL to 1. The A-Law table is fixed, so no setup is required. When the input is wider than 10 bits, the [CCDC\\_ALAW](#) [2:0] GWDI bit is used to select which 10 bits of the 12 possible bits are selected for compression. See [Table 6-66](#).

**Table 6-66. Camera ISP CCDC CCDC\_ALAW [2:0] GWDI**

| GWDI   | Description  |
|--------|--------------|
| 4      | Bits 11 to 2 |
| 5      | Bits 10 to 1 |
| 6      | Bits 9 to 0  |
| Others | Reserved     |

### 6.5.6.6.2.6.3 Camera ISP CCDC Culling

Culling performs a horizontal and vertical decimation function. The horizontal and vertical culling patterns are set by the [CCDC\\_CULLING](#) register.

- The 8-bit [CCDC\\_CULLING\[31:24\]](#) CULHEVN and [CCDC\\_CULLING\[23:16\]](#) CULHODD bit fields set the horizontal culling pattern for even and odd lines. A 1 means that the pixel is retained; a 0 means that the pixel is skipped. The same number of retained pixels must be set for even and odd lines.
- The 8-bit [CCDC\\_CULLING\[7:0\]](#) CULV bit field sets the vertical culling pattern. The LSB represents the top line and the MSB represents the bottom line. A 1 means that the line is retained; a 0 means that the line is skipped.

### 6.5.6.6.2.6.4 Camera ISP CCDC Data Packing

Pixel data are stored to memory in little-endian format (bytes at lower addresses have lower significance). By default, pixel data are stored in 16-bit words; unused bits are filled with zeros.

If the input data is 8 bits, or if A-Law compression is enabled, the data can be stored in 8-bit words by setting the [CCDC\\_SYN\\_MODE\[11\]](#) PACK8 bit to 1.

If the input data is 12, 11, 10, or 9 bits, and A-Law compression is not enabled, the 8 MSBs are stored to memory.

[Figure 6-117](#) shows data packing and pixel ordering.

**Figure 6-117. Camera ISP CCDC Data Packing - Pixel Ordering**

|               | 3    | 2     | 1     | 0     | 0     |
|---------------|------|-------|-------|-------|-------|
|               | 1    | 4     | 5     | 7     | 0     |
| 12 bits       | 0    | pix 1 |       | 0     | pix 0 |
| 11 bits       | 0    | pix 1 |       | 0     | pix 0 |
| 10 bits       | 0    | pix 1 |       | 0     | pix 0 |
| 9 bits        | 0    | pix 1 |       | 0     | pix 0 |
| 8 bits        | 0    | pix 1 |       | 0     | pix 0 |
| 8 bits packed | pix3 |       | pix 2 | pix 1 | pix 0 |

camisp-118

### 6.5.6.6.2.6.5 Camera ISP CCDC Clipping Window

Before data is stored in memory, a clipping window can be set; only a selected sensor area is stored to memory. [Figure 6-118](#) shows the settings; only the white area is stored to memory.

- The valid-data horizontal start position is controlled with the [CCDC\\_HORZ\\_INFO\[30:16\]](#) SPH bit field. The valid-data vertical start position is controlled with the [CCDC\\_VERT\\_START](#) register. If the sensor is interlaced, the vertical start position for even and odd fields can be configured independently with the [CCDC\\_VERT\\_START](#) register. If the sensor is progressive, the [CCDC\\_VERT\\_START\[14:0\]](#) SLV1 bit field is ignored.
- The valid-data horizontal size is controlled with the [CCDC\\_HORZ\\_INFO\[14:0\]](#) NPH bit field. The horizontal size must be a multiple of 16 pixels. The valid-data vertical size is controlled with the [CCDC\\_VERT\\_LINES\[14:0\]](#) NLV register.

**Figure 6-118. Camera ISP CCDC Clipping Window Before Output to Memory**

camisp-119

#### 6.5.6.6.2.6.6 Camera ISP CCDC Output to Memory

The output formatter memory write enable is controlled by the [CCDC\\_SYN\\_MODE\[17\]](#) WEN bit. The output of the data reformatter can be written to memory by setting [CCDC\\_SYN\\_MODE\[18\]](#) VP2SDR to 1.

The pixel data at the output of the output formatter is written to the address given by the [CCDC\\_SDR\\_ADDR](#) register. The address should be aligned on a 32-byte boundary. The 5 LSBs are ignored. Reading the register always shows the 5 LSBs as 0.

A destination pitch can be set with the [CCDC\\_HSIZE\\_OFF](#) register. The offset must be a multiple of 32 bytes. The 5 LSBs are ignored. Reading the register always shows the 5 LSBs as 0. It is required for the pixel line length to be a multiple of 32 bytes to be stored in memory without holes.

The [CCDC\\_SDOFST](#) register controls how the pixels are stored to memory.

Data to be written to memory can be qualified by the external cam\_wen signal. This feature can be enabled by setting the [CCDC\\_SYN\\_MODE\[5\]](#) EXWEN bit. The [CCDC\\_CFG \[8\]](#) WENLOG bit configures how the cam\_wen signal is used with the internally generated valid signal.

The data can be swapped on a byte basis with the [CCDC\\_CFG\[12\]](#) BSWD bit.

If [CCDC\\_SYN\\_MODE\[13:12\]](#) INPMOD = 1, the MSB of the 8-bit chroma component can be inverted by setting [CCDC\\_CFG\[13\]](#) MSBINVI to 1.

### 6.5.6.7 Camera ISP CCDC Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the CCDC. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- If the memory output port is enabled, the memory output line offset and address should be on 32-byte boundaries.
- If faulty-pixel correction is enabled, the [CCDC\\_FPC\\_ADDR](#) address should be on a 64-byte boundary.
- External WEN cannot be used when the VP2SDR path is enabled.
- If the formatter is enabled, in line-alternating mode, the vertical start and end number should be even.
- The horizontal number for the video port must be =  $1376 \times 4$ .
- If the video port is enabled, [CCDC\\_VP\\_OUT\[30:17\]](#) VERT\_NUM must be [CCDC\\_FMT\\_VERT\[12:0\]](#) FMTLNV.
- The video port must be enabled if the formatter is enabled.
- In YCC input mode:
  - The [CCDC\\_COLPTN](#) must be set to 0s.
  - The [CCDC\\_BLKCMP](#) must be set to 0s.
  - Faulty-pixel correction must be disabled.
  - The video port must be disabled.
  - The formatter must be disabled.
  - The VP2SDR must be disabled.
  - The low-pass filter must be disabled.
  - The A-Law must be disabled.
- In RAW input mode, the resizer output path should not be enabled.

### 6.5.7 Programming the Preview Engine

This section discusses issues related to software control of the preview engine. It lists which registers are required to be programmed in different modes, how to enable and disable the preview engine, and how to check the status of the preview engine; discusses the different register access types; and enumerates programming constraints.

#### 6.5.7.1 Camera ISP Preview Setup/Initialization

This section discusses the configuration of the preview engine required before image processing can begin.

##### 6.5.7.1.1 Camera ISP Preview Reset Behavior

On hardware reset of the camera ISP, all registers in the preview engine are reset to their reset values. However, because the preview engine programmable tables (gamma, noise filter, luminance enhancer, and CFA coefficients) are stored in internal memory, their contents do not have reset values. If the reset is a chip-level power-on reset (reset after power is applied), the contents of these tables are unknown. If the reset is a camera ISP module reset (when power remains active), the contents of these tables remain the same as before the reset.

##### 6.5.7.1.2 Camera ISP Preview Register Setup

Before enabling the preview engine, the hardware must be correctly configured through register writes. [Table 6-67](#) identifies the register parameters that must be programmed before enabling the preview engine.

**Table 6-67. Camera ISP Preview Engine Required Configuration Parameters**

| <b>Function</b>         | <b>Configuration Required</b>                                                                                                                                                                                                                                                                                                                                                                                                    |

#### 6.5.7.1.3 Camera ISP Preview Table Setup

The three gamma memories, noise filter threshold memory, noise filter strength memory, luminance enhancer memory, and the CFA coefficient memory must be filled in before the operation of the preview engine, if their respective functions are enabled.

Two registers allow memory contents to be read and written:

- The address register is used to select the specific table entry: [PRV\\_SET\\_TBL\\_ADDR](#).
- The data register contains the data to be written to the specified location: [PRV\\_SET\\_TBL\\_DATA](#).

While the data register is 20 bits wide, only the 8 LSB data is used for the gamma, noise filter, and CFA filter tap memories.

The preview engine supports linear increments on reads and writes automatically. The following examples show how the programmer can read/write the memory. If data is read/written, the address pointer is automatically incremented. For random/noncontiguous reads/writes, [PRV\\_SET\\_TBL\\_ADDR](#) register must be modified.

---

**NOTE:** The address is not autoincremented when the preview engine is busy and users try to read/write the tables.

---

#### Example:

##### Read/write all the entries of the CFA table (using linear increment):

- WRITE (SET\_TBL\_ADDR, 0x1400);
- READ (SET\_TBL\_DATA, 0xvalue1);
- WRITE (SET\_TBL\_DATA, 0xvalue2);
- READ (SET\_TBL\_DATA, 0xvalue3);
- Etc. . . .
- READ (SET\_TBL\_DATA, 0xvalue163F);

**Read/write selective entries of the tables (have to program the address separately for each read/write)**

- WRITE (SET\_TBL\_ADDR, 11);
- READ (SET\_TBL\_DATA, value11);
- WRITE (SET\_TBL\_ADDR, 564);
- WRITE (SET\_TBL\_DATA, value564);

#### 6.5.7.2 Camera ISP Preview Enable/Disable Hardware

Setting the [PRV\\_PCR\[0\]](#) ENABLE bit to 0x1 enables the preview engine. This must be done after all required registers and tables are programmed.

When the input source is the memory, the preview engine always operates in one-shot mode. In other words, after enabling the preview engine, the ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begin immediately on setting the ENABLE bit.

When the input source is the CCDC, the preview engine can be configured to operate in either one-shot mode or continuous mode ([PRV\\_PCR \[3\]](#) ONESHOT). Processing of the frame is depends on the timing of the CCDC. To ensure that data from the CCDC is not missed, the preview engine must be enabled before the CCDC so that it waits for CCDC data.

---

**NOTE:** In one-shot mode, on setting the ENABLE bit, the processing of the frame begins and the ENABLE, ONESHOT, and SOURCE bits are reset to their reset values.

---

When the preview engine is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

#### 6.5.7.3 Camera ISP Preview Events and Status Checking

The preview engine generates an interrupt at the end of each frame.

The status of this interrupt can be checked by reading the [ISP IRQ0STATUS](#) register (or [ISP IRQ1STATUS](#)). When the read of the register [ISP IRQ0STATUS](#) occurs (or [ISP IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the PRV\_DONE\_IRQ bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP IRQ0ENABLE](#) register (or [ISP IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP IRQ0ENABLE\[x\] = 0](#)), the correspondent status ([ISP IRQ0STATUS \[x\] = 1](#)) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The [PRV\\_PCR\[1\]](#) BUSY status bit is set when the start of frame occurs (if the [PRV\\_PCR\[0\]](#) ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [PRV\\_PCR\[1\]](#) BUSY status bit may be polled to determine end-of-frame status.

The [PRV\\_PCR\[31\]](#) DRK\_FAIL status bit is set when dark-frame data fetched from memory arrives late. This bit can be reset by writing a 1 to the bit.

#### 6.5.7.4 Camera ISP Preview Register Accessibility During Frame Processing

There are three types of register access in the preview engine.

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- [PRV\\_PCR](#)
- [PRV\\_RSDR\\_ADDR](#)

- [PRV\\_RADR\\_OFFSET](#)
- [PRV\\_DSDR\\_ADDR](#)
- [PRV\\_DRKF\\_OFFSET](#)
- [PRV\\_WSDR\\_ADDR](#)
- [PRV\\_WADD\\_OFFSET](#)
- Busy-writable registers: These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.  
The busy-writable registers are:
  - [PRV\\_WB\\_DGAIN](#)
  - [PRV\\_WBGAIN](#)
- Busy-lock registers:
  - All registers EXCEPT the shadow and busy-writable registers belong to this category. Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective, but allowed writes from software perspective).
  - After the [PRV\\_PCR\[1\]](#) BUSY bit is reset to 0, busy-lock registers can be written.
  - The [PRV\\_SET\\_TBL\\_DATA](#) register cannot be read when the preview engine is busy, because this register is mapped to memories internally. Such reads return indeterminate data. Byte enables are not implemented for reading preview engine memories.

The ideal procedure for changing the preview engine registers is:

```
IF (PRV_PCR\[1\] BUSY == 0) OR IF
(EOF interrupt occurs)
 DISABLE PREVIEW ENGINE
 CHANGE REGISTERS
 ENABLE PREVIEW ENGINE
```

#### 6.5.7.5 Camera ISP Preview Interframe Operations

Between frames, it may be necessary to enable/disable functions or modify memory pointers. Because the [PRV\\_PCR](#) register and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

#### 6.5.7.6 Camera ISP Preview Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the preview engine. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- A frame can only be read from memory when the SBL read port is affected to the PREVIEW module ([ISP\\_CTRL\[27\]](#) SBL\_SHARED\_RPORTA = 0)
- The shading compensation feature can only be used when the SBL read port is affected to the PREVIEW module ([ISP\\_CTRL\[28\]](#) SBL\_SHARED\_RPORTB = 0)
- If the memory output port is enabled, the memory output line offset and address should be on 32-byte boundaries.
- The output width must be less than or equal to 4096.
- The output width must be even.
- Input to the horizontal median filter must be even.
- Defect correction can only be used when noise filter is enabled
- Input height must be smaller than CCDC output height.
- The input width of the preview engine must be a multiple of the average count multiplied by the least

common multiple of the odd distance and even distance of the averager.

- $(\text{PRV\_HORZ\_INFO}[13:0] \text{ EPH} - \text{PRV\_HORZ\_INFO}[29:16] \text{ SPH} + 1) \bmod ((1 \text{ PRV\_AVE}[1:0] \text{ COUNT}) * \text{LeastCommonMultiple}(\text{PRV\_AVE}[5:4] \text{ ODDDIST}+1, \text{PRV\_AVE}[3:2] \text{ EVENDIST}+1)) = 0$
- Input width must be at least 4 pixels smaller than CCDC output width:
  - $\text{PRV\_HORZ\_INFO}[29:16] \text{ SPH}$  at least 2 pixels before last pixel from CCDC
  - $\text{PRV\_HORZ\_INFO}[13:0] \text{ EPH}$  at least 2 pixels before last pixel from CCDC

### **6.5.8 Programming the Resizer**

This section discusses issues related to software control of the resizer. It lists which registers are required to be programmed in different modes, how to enable and disable the resizer, and how to check the status of the resizer; discusses the different register access types; and enumerates programming constraints.

#### **6.5.8.1 Camera ISP Resizer Setup/Initialization**

This section discusses the configuration of the resizer required before image processing can begin.

##### **6.5.8.1.1 Camera ISP Resizer Reset Behavior**

On hardware reset of the camera ISP, all registers in the resizer are reset to their reset values.

##### **6.5.8.1.2 Camera ISP Resizer Register Setup**

Before enabling the resizer, the hardware must be correctly configured through register writes. [Table 6-69](#) identifies the register parameters that must be programmed before enabling the resizer.

**Table 6-69. Camera ISP Resizer Required Configuration Parameters**

| Function                   | Configuration Required                                                                                                             |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| Resizer control parameters | <a href="#">RSZ_CNT</a>                                                                                                            |
| IO sizes                   | <a href="#">RSZ_OUT_SIZE</a><br><a href="#">RSZ_IN_START</a><br><a href="#">RSZ_IN_SIZE</a>                                        |
| Memory addresses           | <a href="#">RSZ_SDR_INADD</a><br><a href="#">RSZ_SDR_INOFF</a><br><a href="#">RSZ_SDR_OUTADD</a><br><a href="#">RSZ_SDR_OUTOFF</a> |
| Filter coefficients        | <a href="#">RSZ_HFILT10</a> to <a href="#">RSZ_HFILT3130</a><br><a href="#">RSZ_VFILT10</a> to <a href="#">RSZ_VFILT3130</a>       |
| Edge enhancement           | <a href="#">RSZ_YENH[17:16]</a> ALGO                                                                                               |

The edge-enhancement function is optional:

- If it is disabled, the rest of the [RSZ\\_YENH](#) register does not need to be programmed.
- If it is enabled, the edge-enhancement parameters in [Table 6-70](#) must be programmed so that the edge-enhancement function operates correctly.

[Table 6-70](#) can be read as:

If (**Condition** is TRUE) then

**Configuration required** parameters must be programmed.

**Table 6-70. Camera ISP Resizer Conditional Configuration Parameters**

| Function         | Condition                         | Configuration Required                                            |
|------------------|-----------------------------------|-------------------------------------------------------------------|
| Edge enhancement | RSZ_YENH[17:16] ALG0 = 0x1 or 0x2 | RSZ_YENH[15:12] GAIN<br>RSZ_YENH[11:8] SLOP<br>RSZ_YENH[7:0] CORE |

### 6.5.8.2 Camera ISP Resizer Enable/Disable Hardware

Setting the [RSZ\\_PCR\[0\]](#) ENABLE bit to 0x1 enables the resizer. This must be done after all required registers are programmed.

When the input source is memory, the resizer always operates in one-shot mode. In other words, after enabling the resizer, the [RSZ\\_PCR\[0\]](#) ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory.

In this mode, fetching and processing of the frame begin immediately on setting the [RSZ\\_PCR\[0\]](#) ENABLE bit.

When the input source is the CCDC or preview engine, the resizer can be configured to operate in either one-shot mode, or continuous mode ([RSZ\\_PCR\[2\]](#) ONESHOT). Processing of the frame depends on the timing of the CCDC/Preview. To ensure that data from the CCDC or preview engine is not missed, the resizer must be enabled before these upstream modules, so it waits for data from the CCDC or the preview engine.

When the resizer is started during an ongoing frame the enable is latched at the end of the frame it was written in.

When the resizer is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it was written.

### 6.5.8.3 Camera ISP Resizer Events and Status Checking

The resizer generates an interrupt event at the end of each frame.

The status of this interrupt can be checked by reading the [ISP IRQ0STATUS](#) register (or [ISP IRQ1STATUS](#)). When the read of the register [ISP IRQ0STATUS](#) occurs (or [ISP IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the RSZ\_DONE\_IRQ bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP IRQ0ENABLE](#) register (or [ISP IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP IRQ0ENABLE\[x\] = 0](#)), the correspondent status ([ISP IRQ0STATUS\[x\] = 1](#)) bit is flagged, if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The [RSZ\\_PCR\[1\]](#) BUSY status bit is set when the start of frame occurs (if the [RSZ\\_PCR\[0\]](#) ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [RSZ\\_PCR\[1\]](#) BUSY status bit may be polled to determine end-of-frame status in oneshot mode. [Figure 6-119](#) shows the firmware/hardware interaction. Configuration registers and filter coefficients are programmed in-between or before busy periods, before writing ENABLE to 0x1.

**Figure 6-119. Camera ISP Resizer Firmware Interactions for Memory-Input Resizing**

**NOTE:** The [SBL\\_SDR\\_REQ\\_EXP\[19:10\]](#) RSZ\_EXP bit field enables the spreading of non-real time read requests over time. It is useful to avoid overflow situations when the resizer module is programmed to work from memory to memory.

#### 6.5.8.4 Camera ISP Resizer Register Accessibility During Frame Processing

There are two types of register access in the resizer.

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- [RSZ\\_PCR](#)
- [RSZ\\_SDR\\_INADD](#)
- [RSZ\\_SDR\\_INOFF](#)
- [RSZ\\_SDR\\_OUTADD](#)
- [RSZ\\_SDR\\_OUTOFF](#)
- Busy-lock registers
  - All registers EXCEPT the shadowed registers belong to this category.
  - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective; allowed write from software perspective).
  - After the [RSZ\\_PCR\[1\]](#) BUSY bit is reset to 0, the busy-lock registers can be written.

The ideal procedure for changing the resizer registers is:

```
IF (RSZ_PCR\[1\] BUSY == 0) OR IF
(EOF interrupt occurs)
 DISABLE RESIZER
 CHANGE REGISTERS
 ENABLE RESIZER
```

#### 6.5.8.5 Camera ISP Resizer Inter-Frame Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Because the [RSZ\\_PCR\[0\]](#) ENABLE bit and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is get latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

**NOTE:** The firmware must compute and upload the filter coefficients. If polyphase resampling is used, a different set is required when changing between 4-tap and 7-tap modes, and with different downsampling factors; all upsampling factors can share the same set of coefficients. Do not change any busy-lock registers while the resizer is operating. Specifically, when back-to-back resizes require changes in any busy-lock registers (such as the coefficients, resizing ratios, input and output sizes), users must wait for the first resize to complete. The following section describes some scenarios where this is required.

#### 6.5.8.5.1 Camera ISP Resizer Multiple Passes for Large Resizing Operations

The resizer supports multiple passes of processing for large resizing operations. "Large" has the following meanings:

- Wider output than 4096 pixels: This works only in memory input mode. Input can be partitioned into multiple resizer blocks, and each block is separately resized and stitched together. Having input/output memory line offsets, input starting pixel and starting phase are essential to make this work. The basic idea is to begin subsequent slices at exactly where previous images leave off. The starting phase and pixel registers can be programmed to this exact location.
- Larger than 4x upsampling: Resizing can be applied in multiple passes. For example, 10x upsampling can be realized by first a 4x upsampling, then a 2.5x upsampling. The first pass can be performed on-the-fly with the preview engine. The second pass can be performed only with input from memory, and for 10x digital zoom; there is time outside the active picture region to perform the second pass.
- Larger than 4:1 downsampling: Although it is rarely necessary to generate a very small image from a large image, this is supported by the hardware. For example, 10x downsampling can be realized first with 4x downsampling on-the-fly with the preview engine, then 2.5x downsampling in the memory-input path. There may not be much time outside the active data region for the second pass, but since the image is already reduced to 1/16 of its original size, not much time is necessary. Typically, sensor or video input has 10 ~ 20 % of usable vertical blanking.

For all these scenarios, the second pass can be configured and initiated from an interrupt service routine triggered by the resizer end-of-frame interrupt: [ISP IRQ0ENABLE\[24\]](#) RSZ\_DONE\_IRQ (or [ISP IRQ1ENABLE](#)).

#### 6.5.8.5.2 Camera ISP Resizer Processing Time Calculation

The time calculated below is the time it takes for all resizes where the input source is memory (second pass when doing a 10x resize in preview mode; in the case of a 10x resize in preview mode, the first pass is hidden behind the time it takes to capture and process the image from the sensor based on cam\_pclk and the number of lines resized).

The following equation can be used to determine the processing time of the resizer when the input is from memory and therefore how much time it takes before it can switch back to preview input mode:

$$\text{Time} = [W \times \text{bytes\_per\_pixel} \times H]/[L3/2] \quad (4)$$

Where:

/\* If the input is YUV422 and horizontal downsampling is performed: \*/

```
if ((RSZ_CNT[27] INPTYP ==0) ((RSZ_CNT[9:0] HRSZ + 1) 256))
```

W = average (input\_width, output width); /\* output width includes extra 4 pixels if edge enhancement is enabled\*/

else

W = max(input width, output width); /\*output width includes extra 4 pixels if edge enhancement is enabled\*/

$$\begin{aligned} \text{input\_width} &= \text{RSZ\_IN\_SIZE}[12:0]\text{HORZ} \\ \text{output\_width} &= \text{RSZ\_OUT\_SIZE}[11:0]\text{HORZ} \\ \text{input\_height} &= \text{RSZ\_IN\_SIZE}[28:16]\text{VERT} \\ \text{bytes\_per\_pixel} &= \begin{cases} 1, & \text{when RSZ\_CNT[27]INPTYP = 1 (color separate)} \\ 2, & \text{when RSZ\_CNT[27]INPTYP = 0 (YUV422)} \end{cases} \end{aligned}$$

camisp-E097

This time is the baseline steady state calculation of the hardware and does not include the time it takes for the hardware to fetch the first input and fill the Video processing hardware. It also does not include the time spent from the last output from the resizer to get back to memory when the resizer interrupt occurs.

However, these beginning and ending times are relatively negligible.

Depending on real-time constraints, this processing time may be much faster than is required. (data fetches can be delayed from memory to free more bandwidth for use by other system peripherals; see [Section 6.5.11.5.2, Input from Memory](#).

#### **6.5.8.6 Camera ISP Resizer Summary of Constraints**

The following is a list of register configuration constraints to adhere to when programming the resizer. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- Vertical and horizontal resize ratio values must be within the following range: [64..1024].
- Output width:
  - Must be within the maximum limit:
    - width 4096 (if vertical resize value is in range:  $(\text{RSZ_CNT}[19:10] \text{ VRSZ} + 1) = [64..512]$ )
    - width 2048 (if vertical resize value is in range:  $(\text{RSZ_CNT}[19:10] \text{ VRSZ} + 1) = [513..1024]$ )
  - Must be even
  - Must be a multiple of 16 bytes (for vertical upsizing)
- When input is from preview engine/CCDC:
  - The input height and width must be = the output of the preview engine/CCDC.
  - The input address and offset must be zero.
  - The input cannot be color-separated data.
- If the source is memory:
  - The vertical start pixel must be zero.
  - The horizontal start pixel must be within the range: 0:15 for color interleaved, 0:31 for color separate data.
  - The memory output line offset and address must be on 32-byte boundaries.
- Input height and width MUST adhere to the equations in [Table 6-71](#).

**Table 6-71. Camera ISP Resizer How to Set Input Height and Width**

|                                          | 8-phase, 4-tap mode                                            | 4-phase, 7-tap mode                                            |
|------------------------------------------|----------------------------------------------------------------|----------------------------------------------------------------|
| <a href="#">RSZ_IN_SIZE</a> [12:0] HORZ  | $(32 * \text{sph} + (\text{ow} - 1) * \text{hrs}z + 16) 8 + 7$ | $(64 * \text{sph} + (\text{ow} - 1) * \text{hrs}z + 32) 8 + 7$ |
| <a href="#">RSZ_IN_SIZE</a> [28:16] VERT | $(32 * \text{spv} + (\text{oh} - 1) * \text{vrs}z + 16) 8 + 4$ | $(64 * \text{spv} + (\text{oh} - 1) * \text{vrs}z + 32) 8 + 7$ |

Where:

- sph = Start phase horizontal ([RSZ\\_CNT\[22:20\]](#) HSTPH)
- spv = Start phase vertical ([RSZ\\_CNT\[25:23\]](#) VSTPH)
- ow = Output width ([RSZ\\_OUT\\_SIZE\[11:0\]](#) HORZ + extra)
- oh = Output height ([RSZ\\_OUT\\_SIZE\[27:16\]](#) VERT)
- hrsz = Horizontal resize value ([RSZ\\_CNT\[9:0\]](#) HRSZ + 1)
- vrsz = Vertical resize value ([RSZ\\_CNT\[19:10\]](#) VRSZ +1)
- extra = 0 when [RSZ\\_YENH\[17:16\]](#) ALGO = 0 (edge enhancement disabled)
- extra = 4 when [RSZ\\_YENH\[17:16\]](#) ALGO != 0 (edge enhancement enabled)

**NOTE:** Normally, (for example, for a QVGA display or encoded PAL video), the output size, not the input size, matters. The image provided by preview/CCDC/memory must have an adequate output size: at least [RSZ\\_IN\\_SIZE\[12:0\]](#) HORZ x [RSZ\\_IN\\_SIZE\[28:16\]](#) VERT. If the image is bigger, the resizer can crop extra pixels.

The phase is usually computed to keep the center of the image at the same location. This permits a natural-looking continuous digital zoom.

For this reason, [Table 6-71](#) explains how to compute [RSZ\\_IN\\_SIZE\[12:0\]](#) HORZ , [RSZ\\_IN\\_SIZE\[28:16\]](#) VERT, not how to compute the output size.

## 6.5.9 Programming the H3A

This section discusses issues related to software control of the H3A module. It lists which registers are required to be programmed in different modes, how to enable and disable the H3A, and how to check the status of the H3A. It also discusses the different register access types and enumerates programming constraints.

### 6.5.9.1 Camera ISP H3A Setup/Initialization

This section discusses the configuration of the H3A required before image processing can begin.

#### 6.5.9.1.1 Camera ISP H3A Reset Behavior

On hardware reset of the camera ISP, all registers in the H3A are reset (set to their reset values).

#### 6.5.9.1.2 Camera ISP H3A Register Setup

For register configuration, the AF engine and the AEW engine of the H3A can be independently be configured. Because there are separate enable bits for each engine, so this section discusses the AF engine and the AEW engine separately.

##### 6.5.9.1.2.1 Camera ISP H3A AF Engine

Before enabling the AF engine, the hardware must be correctly configured through register writes.

[Table 6-72](#) identifies the register parameters that must be programmed before enabling the AF engine of the H3A.

**Table 6-72. Camera ISP H3A AF Engine Required Configuration Parameters**

| Function                  | Configuration Required                                                        |
|---------------------------|-------------------------------------------------------------------------------|
| AF optional preprocessing | <a href="#">H3A_PCR[2]</a> AF_MED_EN<br><a href="#">H3A_PCR[1]</a> AF_ALAW_EN |
| AF mode configuration     | <a href="#">H3A_PCR[13:11]</a> RGBPOS<br><a href="#">H3A_PCR[14]</a> FVMODE   |

**Table 6-72. Camera ISP H3A AF Engine Required Configuration Parameters (continued)**

| Function                         | Configuration Required                                                                                                   |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Paxel start and size information | <a href="#">H3A_AFPAX1</a><br><a href="#">H3A_AFPAX2</a><br><a href="#">H3A_AFPAXSTART</a><br><a href="#">H3A_AFIRSH</a> |
| Memory address                   | <a href="#">H3A_AFBUFST</a>                                                                                              |
| Filter coefficients              | <a href="#">H3A_AFCOEF010</a> to <a href="#">H3A_AFCOEF1010</a>                                                          |

The horizontal median filter function is optional.

If it is disabled, the [H3A\\_PCR\[10:3\]](#) MED\_TH does not need to be programmed.

However, if it is enabled, the [H3A\\_PCR\[10:3\]](#) MED\_TH parameter must be programmed so that the horizontal median filter function operates correctly.

[Table 6-73](#) can be read as:

If (**Condition** is TRUE) then

**Configuration required** parameters must be programmed

**Table 6-73. Camera ISP H3A AF Engine Conditional Configuration Parameters**

| Function                 | Condition                            | Configuration Required               |
|--------------------------|--------------------------------------|--------------------------------------|
| Horizontal median filter | <a href="#">H3A_PCR[2]</a> AF_MED_EN | <a href="#">H3A_PCR[10:3]</a> MED_TH |

#### 6.5.9.1.2.2 Camera ISP H3A AEW Engine

Before enabling the AEW engine, the hardware must be correctly configured through register writes.

[Table 6-74](#) identifies the register parameters that must be programmed before enabling the AEW engine of the H3A.

**Table 6-74. Camera ISP H3A AEW Engine Required Configuration Parameters**

| Function                          | Configuration Required                                                                                                        |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| AEW optional preprocessing        | <a href="#">H3A_PCR[17]</a> AEW_ALAW_EN                                                                                       |
| Saturation limit                  | <a href="#">H3A_PCR[31:22]</a> AVE2LMT                                                                                        |
| Window start and size information | <a href="#">H3A_AEWIN1</a><br><a href="#">H3A_AEWINSTART</a><br><a href="#">H3A_AEWINBLK</a><br><a href="#">H3A_AEWSUBWIN</a> |
| Memory address                    | <a href="#">H3A_AEWBUFST</a>                                                                                                  |

#### 6.5.9.2 Camera ISP H3A Enable/Disable Hardware

Setting the [H3A\\_PCR\[0\]](#) AF\_EN bit enables the AF engine, and the [H3A\\_PCR\[16\]](#) AEW\_EN bit enables the AEW engine. This should be done after all required registers are programmed.

The H3A always operates in continuous mode. Because the input to the H3A module is the video-port interface of the CCDC, processing of the frame depends on the timing signals from the CCDC. To ensure that data from the CCDC is not missed, the H3A should be enabled before the CCDC so that it waits for CCDC data.

The AF engine or the AEW engine can be disabled by clearing the [H3A\\_PCR\[0\]](#) AF\_EN or [H3A\\_PCR\[16\]](#) AEW\_EN bit, respectively, during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

### 6.5.9.3 Camera ISP H3A Event and Status Checking

Both the AF engine and the AEW engine generate an interrupt at the end of processing each frame. These interrupt events can be sent to CAM IRQ0 or CAM IRQ1 by setting the H3A\_AWB\_DONE\_IRQ or H3A\_AF\_DONE\_IRQ bits in the [ISP\\_IRQ0ENABLE](#) enable register (or [ISP\\_IRQ1ENABLE](#)).

The status of these interrupts can be checked by reading the [ISP\\_IRQ0STATUS](#) register (or [ISP\\_IRQ1STATUS](#)). When the read of the register [ISP\\_IRQ0STATUS](#) occurs (or [ISP\\_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the corresponding bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP\\_IRQ0ENABLE](#) register (or [ISP\\_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP\\_IRQ0ENABLE\[x\] = 0](#)), the correspondent status ([ISP\\_IRQ0STATUS \[x\] = 1](#)) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

### 6.5.9.4 Camera ISP H3A Register Accessibility During Frame Processing

There are two types of register access in the H3A module:

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.
- The shadowed registers are:
  - [H3A\\_PCR](#)
  - [H3A\\_AFBUFST](#)
  - [H3A\\_AEWBUFST](#)
- Busy-lock registers:
  - All registers EXCEPT the shadowed registers belong to this category.
  - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective, but allowed writes from software perspective).
  - After the busy bit in the PCR register is reset to 0, the busy-lock registers can be written ([H3A\\_PCR \[15\] BUSYAF](#) for AF registers and [H3A\\_PCR \[18\] BUSYAEAWB](#) for AE/AWB registers).

The ideal procedure for changing the H3A registers is:

```
IF (H3A_PCR \[15\] BUSYAF == 0 OR H3A_PCR \[18\] BUSYAEAWB == 0) OR IF (EOF interrupt occurs)
 DISABLE AF or AE/AWB
 CHANGE REGISTERS AF or AE/AWB
 ENABLE AF or AE/AWB
```

### 6.5.9.5 Camera ISP H3A Interframe Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Since the [H3A\\_PCR](#) and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

### 6.5.9.6 Camera ISP H3A Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the H3A. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- The output addresses must be on 64-byte boundaries.
- AF Engine:
  - The pixel horizontal start value must be greater than or equal to the IIR horizontal start position.

- The width and height of the paxels must be even numbers.
- The minimum width of the autofocus paxel must be 16 pixels.
- Paxels cannot overlap the last pixel in a line.
- Paxels must be adjacent to one another.

AEW Engine:

- The width and height of the windows must be even numbers.
- Subsampling windows can only start on even numbers.
- The minimum width of the AE/AWB windows is 6 pixels.

### **6.5.10 Programming the Histogram**

This section discusses issues related to software control of the histogram module. It lists which registers are required to be programmed in different modes, how to enable and disable the histogram, and how to check the status of the histogram; discusses the different register access types; and enumerates programming constraints.

#### **6.5.10.1 Camera ISP Histogram Setup/Initialization**

This section discusses the configuration of the histogram required before image processing can begin.

##### **6.5.10.1.1 Camera ISP Histogram Reset Behavior**

On hardware reset of the camera ISP, all registers in the histogram are reset to their reset values. However, since the histogram output memory is stored in internal memory, its contents do not have reset values. If the reset is a chip-level power-on reset (reset after power is applied), the contents of this memory are unknown. If the reset is a camera ISP module reset (when power remains active), the contents of this memory remain the same as before the reset.

##### **6.5.10.1.2 Camera ISP Histogram Reset of Histogram Output Memory**

Clear the output memory before enabling the histogram. This can be done two ways:

- Writing zeros to the memory through software
- If the [HIST\\_CNT \[7\]](#) CLR bit is set, reading the memory causes it to be reset after the read.

Reads and writes to the output memory are blocked when the [HIST\\_PCR \[1\]](#) BUSY bit is 1.

##### **6.5.10.1.3 Camera ISP Histogram Register Setup**

Before enabling the histogram module, the hardware must be correctly configured through register writes. [Table 6-75](#) identifies the register parameters that must be programmed before enabling the histogram.

**Table 6-75. Camera ISP Histogram Required Configuration Parameters**

| Function                           | Configuration Required                                                                                                                                                                    |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Histogram Control Bits             | <a href="#">HIST_CNT [3]</a> SOURCE<br><a href="#">HIST_CNT[6]</a> CFA<br><a href="#">HIST_CNT [5:4]</a> BINS<br><a href="#">HIST_CNT [2:0]</a> SHIFT<br><a href="#">HIST_CNT [7]</a> CLR |
| White Balance Gain                 | <a href="#">HIST_WB_GAIN</a>                                                                                                                                                              |
| Region n Size and position (n = 0) | <a href="#">HIST_Rn_HORZ</a><br><a href="#">HIST_Rn_VERT</a>                                                                                                                              |

**Table 6-76** can be read as:

If (**Condition** is TRUE) then

**Configuration required** parameters should be programmed

**Table 6-76. Camera ISP Histogram Conditional Configuration Parameters**

| Function           | Condition                 | Configuration Required                                                                       |
|--------------------|---------------------------|----------------------------------------------------------------------------------------------|
| Input from memory  | HIST_CNT [3] SOURCE = 0x1 | HIST_CNT [8] DATSIZ<br>HIST_RADD<br>HIST_RADD_OFF<br>HIST_H_V_INFO                           |
| Less than 256 bins | HIST_CNT [5:4] BINS 3     | HIST_Rn_HORZ (n = 1)<br>HIST_Rn_VERT (n = 1)                                                 |
| Less than 128 bins | HIST_CNT [5:4] BINS 2     | HIST_Rn_HORZ (n = 2)<br>HIST_Rn_VERT (n = 2)<br>HIST_Rn_HORZ (n = 3)<br>HIST_Rn_VERT (n = 3) |

#### 6.5.10.2 Camera ISP Histogram Enable/Disable Hardware

Setting the **HIST\_PCR** [0] ENABLE bit enables the histogram module. This must be done after all required registers are programmed and the output memory has been cleared.

When the input source is the memory, the histogram module always operates in one-shot mode. In other words, after enabling the histogram, the ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begin immediately on setting the ENABLE bit.

When the input source is the CCDC, the histogram always operates in continuous mode. Processing of the frame depends on the timing of the CCDC. To ensure that data from the CCDC is not missed, the histogram must be enabled before CCDC so it waits for CCDC data..

When the histogram is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

#### 6.5.10.3 Camera ISP Histogram Event and Status Checking

The histogram generates an interrupt at the end of each frame.

The status of this interrupt can be checked by reading the **ISP IRQ0STATUS** register (or **ISP IRQ1STATUS**). When the read of the register **ISP IRQ0STATUS** occurs (or **ISP IRQ1STATUS**), the register is not automatically reset. To reset the interrupt, a 1 must be written to the **HIST\_DONE\_IRQ** bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the **ISP IRQ0ENABLE** register (or **ISP IRQ1ENABLE**). When a particular event is not enabled (for example **ISP IRQ0ENABLE[x] = 0**), the corresponding status (**ISP IRQ0STATUS [x] = 1**) bit is flagged if the corresponding event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The **HIST\_PCR** [1] BUSY status bit is set when the start of frame occurs (if the **HIST\_PCR** [0] ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The **HIST\_PCR** [1] BUSY status bit may be polled to determine the end-of-frame status.

#### 6.5.10.4 Camera ISP Histogram Register Accessibility During Frame Processing

There are two types of register access in the histogram module.

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- [HIST\\_PCR](#)
- [HIST\\_RADD](#)
- [HIST\\_RADD\\_OFF](#)
- Busy-lock registers
  - All registers EXCEPT the shadowed registers belong to this category.
  - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective; allowed write from software perspective).
  - After the [HIST\\_PCR](#) [1] BUSY bit is reset to 0, the busy-lock registers can be written.
  - The [HIST\\_DATA](#) register cannot be read when the histogram is busy, because since this register is mapped to memories internally. Such reads return indeterminate data. Byte enables are not implemented for reading the histogram memory.

The ideal procedure for changing the histogram registers is:

```
IF (HIST_PCR [1] BUSY == 0) OR IF (EOF interrupt occurs)
 DISABLE HISTOGRAM
 CHANGE REGISTERS
 ENABLE HISTOGRAM
```

#### 6.5.10.5 Camera ISP Histogram Interframe Operations

Between frames read from memory, it may be necessary to modify the input memory pointers before processing the next frame. Since the [H3A\\_PCR](#) and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The MPU Subsystem can perform these changes on receiving an interrupt.

If continuous frames are processed without clearing the histogram output memory, the bin counters contain the counts of however many images are processed since they were last cleared. To read the bin counters for each frame, the bin counters must be read after each frame is completed, but before the next frame begins (since the counters cannot be read while the [HIST\\_PCR](#) [1] BUSY bit is 1).

If the input source is memory (one-shot mode), the [HIST\\_PCR](#) [0] ENABLE bit must be set once for the frame, and after the frame is completed, the bin counters can be read/cleared before enabling the next frame.

When the input source is the video-port interface of the CCDC (continuous mode), the [HIST\\_PCR](#) [0] ENABLE bit must be set to enable processing of the frame, and cleared after the frame processing begins (the disable is latched in at the end of the frame). This procedure allows only one frame to be processed. After the frame is completed, the bin counters can be read/cleared before enabling the histogram for the next frame.

#### 6.5.10.6 Camera ISP Histogram Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the histogram. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- The input address and line offset must be on 32-byte boundaries.
- A region dimension of 1 (horizontal or vertical or both) is not allowed.

#### 6.5.11 Programming the Central-Resource SBL

This section discusses issues related to the software control of the central-resource SBL. It lists which registers are required to be programmed in different modes, describes how to check the status of the central resource SBL overflow bits, and enumerates programming constraints.

The central-resource SBL controls data interactions between the camera ISP modules and the interface to memory. A small number of registers configure maximum data-read bandwidth in memory-to-memory operations.

### 6.5.11.1 Camera ISP Central-Resource SBL Setup/Initialization

This section discusses the configuration of the central-resource SBL required before image processing can begin.

#### 6.5.11.1.1 Camera ISP Central-Resource SBLReset Behavior

On hardware reset of the camera ISP, all registers in the SBL are reset to their reset values.

#### 6.5.11.1.2 Camera ISP Central-Resource SBLRegister Setup

Before enabling any of the camera ISP modules, the hardware must be correctly configured through register writes to the camera ISP registers. If the preview engine, resizer, or the histogram is reading from memory, the [SBL\\_SDR\\_REQ\\_EXP](#) register must be programmed. The values programmed in each of the three fields (PRV\_EXP, RSZ\_EXP, HIST\_EXP) determines the number of clock cycles required to allow two consecutive read requests from the module.

### 6.5.11.2 Camera ISP Central-Resource SBL Enable/Disable Hardware

The central-resource SBL functionality is always enabled, unless the PRCM idles the clocks to the camera ISP.

#### 6.5.11.3 Camera ISP Central-Resource SBL Event and Status Checking

The SBL generates one interrupt for the write buffer overflow events listed below. Software must check which overflow event has raised the interrupt request, by reading the [SBL\\_PCR](#) register.

See [Table 6-77](#).

**Table 6-77. Camera ISP Central-Resource SBL Write-Buffer Overflow Events**

| Bit                                                   | Event Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SBL_PCR</a> [26] CSI1_CCP2B_CSI2C_WBL_OVF | CSI1/ CCP2B or CSI2C write-buffer memory overflow                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <a href="#">SBL_PCR</a> [25] CSI2A_WBL_OVF            | CSI2A write-buffer memory overflow                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <a href="#">SBL_PCR</a> [24] CCDCPRV_2_RSZ_OVF        | CCDC/PREVIEW to RESIZER input overflow<br>This bit is set if the RESIZER input source is sent to CCDC/PREVIEW engine when the active data (to be resized) has already showed up at the resizer interface. In such a case, resizing for this frame cannot take place and the bit is set. This scenario can happen when a resize of 4x is required per frame. Therefore, the RESIZER must operate in two passes. In the first pass, the input data from CCDC/PREVIEW is directly resized and written to memory. In the second pass, the resized data from the first pass is resized again. The next frame from the CCDC/PREVIEW engine should start only after the second pass on the previous frame is complete. This bit indicates the failure status. |
| <a href="#">SBL_PCR</a> [23] CCDC_WBL_OVF             | CCDC write-buffer memory overflow                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

The status of this interrupt can be checked by reading the [ISP IRQ0STATUS](#) register (or [ISP IRQ1STATUS](#)). When the read of the register [ISP IRQ0STATUS](#) occurs (or [ISP IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written:

- To the corresponding bit(s) in the [SBL PCR](#) registers
- To the OVF\_IRQ bit in the [ISP IRQ0STATUS](#) register (or [ISP IRQ1STATUS](#))

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP IRQ0ENABLE](#) register (or [ISP IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP IRQ0ENABLE\[x\] = 0](#)), the correspondent status ([ISP IRQ0STATUS \[x\] = 1](#)) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The SBL flags no read buffer logic underflow events. These are signaled by the reading module. [Table 6-78](#) lists the read port and corresponding events if they exist.

**Table 6-78. Camera ISP Central-Resource SBL Read-Buffer Underflow Events**

| Read port                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CCDC faulty pixel              | When faulty-pixel correction is used, the pixel frequency is imposed by the camera clock. This imposes read-time constraints to the faulty-pixel table read. When the table read was too slow, the <a href="#">CCDC_FPC</a> [16] FPERR bit is set to 1 and no more faulty pixels are processed for that frame. This error generates an interrupt that can be mapped to DSP or ARM by setting the CCDC_ERR_IRQ bit in the <a href="#">ISP IRQ0ENABLE</a> register (or <a href="#">ISP IRQ1ENABLE</a> ). To clear this interrupt, clear the <a href="#">CCDC_FPC</a> [16] FPERR bit before clearing the <a href="#">ISP IRQ0STATUS</a> [11] CCDC_ERR_IRQ bit (or <a href="#">ISP IRQ1STATUS</a> ). |
| CCDC lens-shading compensation | There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, then the <a href="#">CCDC_LSC_PREFETCH_ERROR</a> event is triggered and an interrupt generated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Preview dark frame             | There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, the <a href="#">PRV_PCR</a> [31] DRK_FAIL status bit is set to indicate a fail. No interrupt is generated by this event.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Preview image from memory      | No error can occur on this port because the preview module stops processing when no image data is ready.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Resizer image from memory      | No error can occur on this port because the resizer module stops processing when no image data is ready.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Histogram image from memory    | No error can occur on this port because the histogram module stops processing when no image data is ready.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| CSI1/CCP2B image from memory   | No error can occur on this port because the CSI1/CCP2B module stops processing when no image data is ready.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

#### 6.5.11.4 Camera ISP Central-Resource SBL Register Accessibility During Frame Processing

The central resource SBL registers are all busy-writable registers.

- Busy-writable registers
  - These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.

#### 6.5.11.5 Camera ISP Central-Resource SBL Camera ISP Bandwidth Adjustments

For memory-to-memory operation, the camera ISP processes data at the highest possible data rate. If this processing returns results long before real-time deadlines, the performance of other peripherals in the system may be negatively affected. The camera ISP offers two kinds of adjustments that can slow down data processing in this situation. One can be made when the sensor input to the CCDC is the input source, and the other can be made when the memory is the source of the input image.

### 6.5.11.5.1 Camera ISP Central-Resource SBL Input From CCDC Video-Port Interface

The video-port interface delivers data at a rate independent of the pixel clock when the data reformatter is enabled. By default, this rate is set to 100 MHz, which is fast enough to support a parallel interface clock of 90 MHz or a CSI/CCP2B /CSI2 clock of 100 MHz. When the pixel clock is at a lower frequency, it is unnecessary for the video-port interface to operate at such a high frequency. The [CCDC\\_FMTCFG \[21:16\]](#) VPIF\_FRQ field of the CCDC can be programmed to reduce the rate at which the video port delivers new data to the other modules (Preview, H3A, and histogram). In effect, this register indirectly controls the output bandwidth of the preview engine, resizer, and H3A. Depending on the input sensor clock, Users can set this field appropriately and balance the bandwidth requirements to memory. [Figure 6-120](#) demonstrates how this register can expand processing time per line for lower PCLK frequencies.

**Figure 6-120. Camera ISP Central-Resource SBL Video-Port Interface Bandwidth Balancing**

camisp-091

### 6.5.11.5.2 Camera ISP Central-Resource SBL Input From Memory

When the input image is from memory, data is fetched from memory and processed at a steady state rate of 200 MB/sec. Depending on the image size and real-time deadline for each frame, this may be much faster than necessary. Such activity can also starve other processes in the system. Internally, when a CAMERA ISP module receives input from memory, the CAMERA ISP makes a read request to the L3 interconnect whenever there is available memory in its internal buffers.

The [SBL\\_SDR\\_REQ\\_EXP](#) register can be programmed to control the rate at which a camera ISP module (Preview, resizer, or histogram) reads the input frame from memory. This indirectly controls the output bandwidth of the preview engine and resizer. Depending on the size of the images and the real-time deadlines, users can set this field appropriately and balance the bandwidth requirements to memory.

The minimum number of cycles (L3) in between read requests used to program the [SBL\\_SDR\\_REQ\\_EXP](#) register can be determined based on the frame size and real-time requirement using the following equation:

$$\text{Number of cycles/request} = (\text{DMA cycles/frame}) / (\text{DMA read requests/frame})$$

In the previous equation, (DMA cycles/frame) is based on a real-time requirement. For example, if the real-time requirement is a frame rate of 1/30 sec and the L3 clock equals the ISP clock, this can be calculated as:

$$(\text{DMA cycles/frame}) = \text{L3 clock} * \text{frame rate} = \text{ISP clock} * 1/30 = 5.53\text{M cycles}$$

The (DMA read requests/frame) is based on the frame size and the alignment in memory. Assuming a VGA (640 x 480) frame size and optimal alignment conditions:

$$(\text{DMA read requests/frame}) = \text{Transfers per line} * \text{number of lines} = 640 \text{ pix/line} * 2 \text{ bytes/pix} / 256 \text{ bytes/xfer} * 480 \text{ lines} = 2400 \text{ requests/frame}$$

In this example, the final equation can now be solved:

$$\text{Number of cycles/request} = 5.53\text{M cycles}/2400 \text{ requests} = 2306 \text{ cycles/request}$$

[Figure 6-121](#) demonstrates how this register can expand processing time for lower real-time requirements.

**Figure 6-121. Camera ISP Central-Resource SBL Memory Read Bandwidth Balancing**

The maximum values that can be written to the [SBL\\_SDR\\_REQ\\_EXP](#) register for the different read requesters is 1023. For the histogram and preview engine, this should be sufficient for the typical size of RAW data frames. However, because the resizer can read a variety of video frame sizes, the field for the resizer is internally multiplied by 32. Therefore, for this example, the [SBL\\_SDR\\_REQ\\_EXP\[19:10\]](#) RSZ\_EXP bit field can be programmed to FLOOR(2306/32) = 72.

The previous equations provide an estimate or a starting point for programming this register. Depending on the system loads and available bandwidth, it may be necessary to reduce this number to compensate for a heavily loaded system.

**NOTE:** The granularity for the resizer, HIST, and preview is 32.

## 6.5.12 Programming the Circular Buffer

### 6.5.12.1 Camera ISP CBUFF Setup/Initialization

This section discusses the configuration of the circular buffer required before address translation can begin.

### 6.5.12.2 Camera ISP CBUFF Reset Behavior

Upon hardware reset of the circular buffer, all of the registers in the circular buffer are reset to their reset values.

### 6.5.12.3 Camera ISP CBUFF Register Setup

All registers of the circular buffer to be used (CBUFFx, x=0 or 1) have to be initialized for correct operation.

The [CBUFFx\\_START](#) and [CBUFFx\\_END](#) register define the virtual address range managed by the circular buffer. It usually corresponds to the address region where one image frame is written by the camera ISP.

The window count and size are set through the [CBUFFx\\_CTRL \[9:8\]](#) WCOUNT and [CBUFFx\\_WINDOWSIZE](#) registers. The window size usually depends on the utilization of the buffer. 8 or 16 video lines correspond to a current size for JPEG video compression. A higher window count provides better latency related overflow protection.

When the camera ISP accesses data in an incremental addressing scheme, the next window is never used. In this case the overflow event generation, when the processor window falls into the "next window", can be disabled by setting the [CBUFFx\\_CTRL \[3\]](#) ALLOW\_NW\_EQ\_CPUW flag.

When the 2D addressing capability is not used the **CBUFFx\_THRESHOLD** register is set to the window size. Otherwise it is set to a smaller value depending on the buffer organization. For example, when each window corresponds to 8 lines by 4096 pixel but the camera ISP only send lines of 2560 pixels the **CBUFFx\_WINDOWSIZE**=8\*4096 and **CBUFFx\_THRESHOLD**=8\*2560.

When the register setup is completed the module is enabled using the **CBUFFx\_CTRL** [0] EN bit.

It can be disabled by clearing the **CBUFFx\_CTRL** [0] EN bit. This must only be done when there are no more outstanding requests to the virtual space managed by CBUFFx. All internal FSMs and counters of the circular buffer are reset when it is disabled. Pending interrupts are not affected.

#### 6.5.12.4 Camera ISP CBUFF Event and status Checking

##### 6.5.12.4.1 Camera ISP CBUFF Interrupts

All events generated by the circular buffer are mapped to an unique event at camera ISP level: CBUFF\_IRQ,

The CBUFF module event can be mapped to the MPU SS or to the IVA SS.

The CBUFF\_IRQ bit in the **ISP IRQ0ENABLE** [21] CBUFF\_IRQ register control whether the CBUFF module event triggers an interrupt to the MPU SS. The CBUFF\_IRQ bit in the **ISP IRQ0ENABLE** [21] CBUFF\_IRQ register control whether the CBUFF module event triggers an interrupt to the IVA2.2 SS.

When an event has been triggered the **ISP IRQ0STATUS** [21] CBUFF\_IRQ bit is set (or **ISP IRQ1STATUS**). SW must than read the **CBUFF IRQSTATUS** register to know which circular buffer event has triggered the interrupt. SW must clear the event first in the circular buffer module by writing 1 to the proper bit in **CBUFF IRQSTATUS** register and then clear the event at camera ISP level by writing 1 to the **ISP IRQ0STATUS** [21] CBUFF\_IRQ bit (or **ISP IRQ1STATUS**). If another event is pending at circular buffer level, the CBUFF\_IRQ interrupt is triggered again.

##### 6.5.12.4.2 Camera ISP CBUFF Status Checking

The event status can be checked through the CBUFFx\_READY\_IRQ, CBUFFx\_INVALID\_IRQ, and CBUFFx\_OVR\_IRQ bits in the **CBUFF IRQSTATUS** registers.

In addition to those status bits the circular buffer module provides read only access to the "current window", "next window" and "CPU windows" indexes through the **CBUFFx\_STATUS** register. The "CPU window" index can for example be used by the processor to compute the address of the physical buffer. Those indexes can also be used to evaluate latency margins.

#### 6.5.12.5 Camera ISP CBUFF Register Accessibility During Frame Processing

All registers are Busy-writeable registers. These registers/fields can be read or written even if the module is busy. Changes to the underlying settings takes place instantaneously. However the module behavior is unpredictable when registers are changed during processing.

For correct operation software must follow the following steps:

- Disable all accesses to the virtual space managed by CBUFFx. For example when the circular buffer relocates data provided by the CCDC module SW must disable the CCDC module and check SBL status registers to make sure there are no more outstanding transactions.
- Disable circular buffer x by clearing the **CBUFFx\_CTRL** [0] ENABLE bit.
- Change the configuration.
- Re-enable CBUFFx by setting the **CBUFFx\_CTRL** [0] ENABLE bit.

#### 6.5.12.6 Camera ISP CBUFF Operations

A CBUFFx\_READY\_IRQ event is generated each time processor can read data from the circular buffer. Processor can clear the event when it starts processing the data to avoid masking of other events. Processor can keep trace of the location on the data internally or use the circular buffer registers to compute it.

The formula used for CBUFF1 is:

$$\text{ADDR} = \text{CBUFFx\_STATUS}[3:0] \text{ CPUW} \times \text{CBUFFx\_WINDOWSIZE} + \text{CBUFFx\_START} \quad (5)$$

Because of the functionality of the fragment, the formula used for CBUFF0 is:

$$\text{ADDR} = \text{CBUFFx\_ADDRy}[\text{CBUFFx\_STATUS}[3:0] \text{ CPUW}] \quad (6)$$

When processor is done with processing, it must free the buffer by setting the **CBUFFx\_CTRL[2]** DONE bit. Otherwise an overflow event may occur.

The circular buffer does not keep trace of end of frame events. They must be managed by the processor using the end of frame event of the module that writes into the circular buffer. At the end of the frame there may remain data in the "current write" and "next write" windows. For example, when the window size is set to 8 lines and the image size is 20 lines only 2 window ready events are generated for a linear addressing scheme. The remaining 4 lines can be read after the end of frame event.

No automatic reset of the CBUFF FSM occurs at the end of the camera ISP frame. Software must reset the CBUFF by clearing the **CBUFFx\_CTRL[0]** ENABLE bit when the frame has been completely processed. A new frame can only start when **CBUFFx\_CTRL [0]** ENABLE has been set.

### 6.5.13 Programming the Camera ISP Software Reset

The flow chart in [Figure 6-122](#) describes the steps to perform a software reset.

**Figure 6-122. Camera ISP Software Reset Sequence**

camisp-404

[Table 6-79](#) lists the registers to configure for the camera subsystem software reset step.

**Table 6-79. Camera ISP Software Register Settings**

| Register Name | Address     | Value Description                                                                                    |
|---------------|-------------|------------------------------------------------------------------------------------------------------|
| ISP_SYSCONFIG | 0x480B C004 | Initiate a software reset. The <b>ISP_SYSCONFIG[1]</b> SOFTRESET is automatically reset by hardware. |
| ISP_SYSSTATUS | 0x480B C008 | The <b>ISP_SYSSTATUS[0]</b> RESETDONE is set to 1 when the reset sequence is done.                   |

## 6.6 Camera ISP Register Manual

### 6.6.1 Camera ISP Instance Summary

**Table 6-80. Camera ISP Instance Summary**

| Module Name      | L3 Base Address | Size     |
|------------------|-----------------|----------|
| ISP_TOP          | 0x480B C000     | 256Bytes |
| ISP_CBUFF        | 0x480B C100     | 256Bytes |
| ISP_CCP2B        | 0x480B C400     | 512Bytes |
| ISP_CCDC         | 0x480B C600     | 512Bytes |
| ISP_HIST         | 0x480B CA00     | 512Bytes |
| ISP_H3A          | 0x480B CC00     | 512Bytes |
| ISP_PREVIEW      | 0x480B CE00     | 512Bytes |
| ISP_RESIZER      | 0x480B D000     | 512Bytes |
| ISP_SBL          | 0x480B D200     | 512Bytes |
| ISP_CSIIA_REGS1  | 0x480B D800     | 368Bytes |
| ISP_CSIPHY2      | 0x480B D970     | 32Bytes  |
| ISP_CSIIA_REGS2  | 0x480B D9C0     | 64Bytes  |
| ISP_CSIC2C_REGS1 | 0x480B DC00     | 368Bytes |
| ISP_CSIPHY1      | 0x480B DD70     | 32Bytes  |
| ISP_CSIC2C_REGS2 | 0x480B DDC0     | 64Bytes  |

---

**NOTE:** The camera ISP instance CAMERA\_ISP\_MMU with L3 base address 0x480B D400 and size 256 bytes is within the camera ISP memory space. For a detailed description of the MMU and register description, see [Chapter 15, Memory Management Units](#).

---

#### 6.6.1.1 Camera ISP Registers Summary

**Table 6-81. ISP Register Mapping Summary**

| Register Name       | Type | Register Width (Bits) | Address Offset | ISP L3 Base Address |
|---------------------|------|-----------------------|----------------|---------------------|
| ISP_REVISION        | R    | 32                    | 0x0000 0000    | 0x480B C000         |

| Bits  | Field Name        | Description                                                                                                                                                                                                                                                                                                                                                                                                             | Type | Reset |
|-------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31    | FLUSH             | CCDC memory flush<br>Writing '1' in this bit flushes the CCDC memories in the central resource SBL. The SBL memories are always flushed by the end of frame. However, there are cases where the end of frame cannot be detected.                                                                                                                                                                                        | RW   | 0     |
| 30    | JPEG_FLUSH        | JPEG flush<br>When a camera module outputs a JPEG bit stream, this bit needs to be set because the bitstream length may not be a multiple of 32 bits. Enabling this bit ensures that no data stay in the design internal FIFOs.                                                                                                                                                                                         | RW   | 0     |
| 29    | CCDC_WEN_POL      | Sets the polarity of the CCDC WEN bit.<br>0x0: Active low<br>0x1: Active high                                                                                                                                                                                                                                                                                                                                           | RW   | 0     |
| 28    | SBL_SHARED_RPORTB | Controls SBL shared read port B access<br>0x0: Read port used by preview module dark frame read<br>0x1: Read port used by CCDC module lens shading compensation data read                                                                                                                                                                                                                                               | RW   | 0     |
| 27    | SBL_SHARED_RPORTA | Controls SBL shared read port A access<br>0x0: Read port used by preview module data read<br>0x1: Read port used by CSI1 module data read                                                                                                                                                                                                                                                                               | RW   | 0     |
| 26    | SBL_SHARED_WPORTC | Controls SBL shared write port C access<br>0x0: CSI1/CCP2B : CCP2 protocol engine<br>0x1: CSI2C : CSI2C protocol engine                                                                                                                                                                                                                                                                                                 | RW   | 0     |
| 25:24 | CBUFF1_BCF_CTRL   | Bandwidth control feedback loop configuration register<br>0x0: Disabled.<br>0x1: The BCF signal of CBUFF1 stalls the response phase of the CSI1/CCP2B Interconnect read master port.<br>0x2: The BCF signal of CBUFF1 stalls the request phase of the CSI1/CCP2B Interconnect read master port.<br>0x3: The BCF signal of CBUFF1 stalls the request and response phase of the CSI1/CCP2B Interconnect read master port. | RW   | 0x0   |
| 23:22 | CBUFF0_BCF_CTRL   | Bandwidth control feedback loop configuration register<br>0x0: Disabled.<br>0x1: The BCF signal of CBUFF0 stalls the response phase of the CSI1/CCP2B Interconnect read master port.<br>0x2: The BCF signal of CBUFF0 stalls the request phase of the CSI1/CCP2B Interconnect read master port.<br>0x3: The BCF signal of CBUFF0 stalls the request and response phase of the CSI1/CCP2B Interconnect read master port. | RW   | 0x0   |
| 21    | SBL_AUTOIDLE      | Sets the SBL autoidle mode<br>0x0: Disabled<br>0x1: Enabled                                                                                                                                                                                                                                                                                                                                                             | RW   | 1     |
| 20    | SBL_WR0_RAM_EN    | This bit controls the SBL module WRITE0 RAM used by the RESIZER module. If the RESIZER module is disabled, this bit shall be set to '0' to save power.<br>0x0: RAM is disabled<br>0x1: RAM is enabled                                                                                                                                                                                                                   | RW   | 0     |
| 19    | SBL_WR1_RAM_EN    | This bit controls the SBL module WRITE1 RAM. If the RESIZER module is the only module enabled to perform memory to memory resize operations, this bit shall be set to '0' to save power.<br>0x0: RAM is disabled<br>0x1: RAM is enabled                                                                                                                                                                                 | RW   | 0     |

| Bits  | Field Name       | Description                                                                                                                                                                                                                                                                                                                                                                                               | Type | Reset |
|-------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 18    | SBL_RD_RAM_EN    | This bit controls the SBL module READ RAM. If no read requests are generated, this bit shall be set to '0' to save power.<br><br>0x0: RAM is disabled<br>0x1: RAM is enabled                                                                                                                                                                                                                              | RW   | 0     |

| <b>Description</b>      | INTERRUPT ENABLE REGISTER - LOGICAL CHANNELS 0 and 1 This register regroups all the events related to logical channel 0 and logical channel 1. The events related to logical channel 0 trigger SINTERRUPTN[0]. The events related to logical channel 1 trigger SINTERRUPTN[1]. The channel is enabled for events to be generated on that channel. |                       |                 |          |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |          |

| <b>Description</b>      | INTERRUPT STATUS REGISTER - LOGICAL CHANNELS 0 and 1 This register regroups all the events related to logical channel 0 and logical channel 1. The events related to logical channel 0 trigger SINTERRUPTN[0]. The events related to logical channel 1 trigger SINTERRUPTN[1]. The channel is enabled for events to be generated on that channel. |                 |          |

| Description      | INTERRUPT ENABLE REGISTER - LOGICAL CHANNELS 2 and 3 This register regroups all the events related to logical channel 2 and logical channel 3. The events related to logical channel 2 trigger SINTERRUPTN[2]. The events related to logical channel 3 trigger SINTERRUPTN[3]. The channel is enabled for events to be generated on that channel. |            |            |            |               |          |                  |             |             |            |             |             |          |            |            |            |            |               |          |                  |             |             |            |             |             |   |   |   |   |   |   |  |  |  |  |

| <b>Description</b>    | INTERRUPT STATUS REGISTER - LOGICAL CHANNELS 2 and 3 This register regroups all the events related to logical channel 2 and logical channel 3. The events related to logical channel 2 trigger SINTERRUPTN[2]. The events related to logical channel 3 trigger SINTERRUPTN[3]. The channel is enabled for events to be generated on that channel. |                         |             |                 |          |

| Bits | Field Name      | Description                                                                                                                                                                                                                                                                                                                                                                  | Type | Reset |
|------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 12   | VP_CLK_POL      | VP clock polarity<br>0x0: The CCP2B RECEIVER module writes the data on the VP on the pixel clock falling edge. The module connected to the VP samples the data on the pixel clock rising edge.<br>0x1: The CCP2B RECEIVER module writes the data on the VP on the pixel clock raising edge. The module connected to the VP samples the data on the pixel clock falling edge. | RW   | 0x0   |
| 11   | VP_ONLY_EN      | VP only enable<br>0x0: The VP is enabled and the Interconnect master port is enabled.<br>0x1: The VP is enabled and the Interconnect master port is disabled. The embedded data and pixel data are output on the VP.                                                                                                                                                         | RW   | 0x0   |
| 10   | INV             | Strobe/clock inversion control signal<br>0x0: Not inverted<br>0x1: Inverted                                                                                                                                                                                                                                                                                                  | RW   | 0x0   |
| 9    | VP_CLK_FORCE_ON | Controls video port clock gating during frame blanking periods.<br>0x0: The video port clock is gated during vertical blanking periods.<br>0x1: The video port clock is free-running during vertical blanking periods.                                                                                                                                                       | RW   | 0x1   |
| 8    | RESERVED        | Write 0s for future compatibility. Read returns 0.                                                                                                                                                                                                                                                                                                                           | R    | 0x0   |
| 7:5  | BURST           | Forces the write burst size used by the module<br>The write burst size must never exceed the output FIFO size. The output FIFO size can be read with the <a href="#">CCP2_GNQ.FIFODEPTH</a> bit field.<br>0x0: 1 x 64-bit burst = single request<br>0x1: 2 x 64-bit bursts<br>0x2: 4 x 64-bit bursts<br>0x3: 8 x 64-bit bursts<br>0x4: 16 x 64-bit bursts                    | RW   | 0x0   |
| 4    | MODE            | Selects the receiver operating mode<br>0x0: MIPI CSI1-compatible mode. When this bit is set, all CCP2B settings are ignored. If the settings are not set correctly to MIPI CSI1 values, the behavior of the receiver is unpredictable.<br>0x1: CCP2B compatible mode                                                                                                         | RW   | 0x0   |
| 3    | FRAME           | Set the modality in which IF_EN works.<br>0x0: When SW writes IF_EN = 0, the interface is disabled immediately.<br>0x1: When SW writes IF_EN = 0, the interface is disabled after the next FEC synchronization code.                                                                                                                                                         | RW   | 0x0   |
| 2    | IO_OUT_SEL      | IO cell output mode selection<br>0x0: RESERVED<br>0x1: MUST BE SET TO 1, IO output is parallel: DATA32, DATATOG, SYNTOG. The SSC_IRQ error can be triggered in this configuration.                                                                                                                                                                                           | RW   | 0x0   |
| 1    | PHY_SEL         | Physical layer protocol selection. Applies for all logical channels<br>0x0: Data/clock physical layer<br>0x1: Data/strobe physical layer                                                                                                                                                                                                                                     | RW   | 0x0   |

| Bits | Field Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Type | Reset |
|------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 0    | IF_EN      | <p>Enables the physical interface to the module</p> <p>0x0: The interface is disabled. If FRAME = 0, it is disabled immediately. If FRAME = 1, it is disabled on the next FEC synchronization code. If FRAME=1, it is advised to disable the logical channels (CCP2_LCX_CTRL.CHAN_EN = 0) before writing IF_EN = 0.</p> <p>0x1: The interface is enabled immediately, the data acquisition starts on the next FSC synchronization code. Writing 1 to this register when the current value is 0 clears the output FIFO. The pixel data of the following frame is written in the PING buffer; that is, the CCP2_LCX_CTRL.PING_PONG bits are also reset to 1.</p> | RW   | 0x0   |

| <b>Description</b>      | DEBUG REGISTER This register provides a way to debug the CCP2B RECEIVER module with no image sensor connected to the module. The debug mode is enabled by <a href="#">CCP2_CTRL.DBG_EN</a> . Each write to this register provides a full 32-bit word to the CCP2B RECEIVER, even when only 8 or 16 bits are written. The newly written value is merged with the previous value (check the example in <a href="#">Section 6.5.3, CCP2 Receiver Basic Programming Model</a> ). |                       |                 |

| Description             | CODE REGISTER - LOGICAL CHANNEL x. This register sets the codes that are used in the 32-bit synchronization codes to recognize the logical channel, frame start, frame end, line start, and line end codes. This register applies for logical channel x only. The default values should not be modified. Updating this register with new codes under a flowing serial transmission on that channel causes unexpected results. |                       |                 |
| Type                    | RW                                                                                                                                                                                                                                                                                                                                                                                                                            |                       |                 |

| <b>Description</b>      | DATA MEMORY PING ADDRESS REGISTER - LOGICAL CHANNEL x. This register sets the 32-bit memory address where the pixel data are stored. The destination is double-buffered; this register sets the PING address. Double-buffering is enabled when the addresses CCP2_LC0_DAT_PING_ADDR and CCP2_LC0_DAT_PONG_ADDR are different. The 5 LSBs are ignored; the address is aligned on a 32-byte boundary. This register is shadowed; modifications are taken into account after the next FSC synchronization code. |                       |                 |

| <b>Description</b>      | DATA MEMORY PONG ADDRESS REGISTER - LOGICAL CHANNEL x. This register sets the 32-bit memory address where the pixel data are stored. The destination is double-buffered; this register sets the PONG address. Double-buffering is enabled when the addresses CCP2_LC0_DAT_PING_ADDR and CCP2_LC0_DAT_PONG_ADDR are different. The 5 LSBs are ignored; the address is aligned on a 32-byte boundary. This register is shadowed; modifications are taken into account after the next FSC synchronization code. |                                                                                    |                 |           |

| <b>Description</b>      | DATA MEMORY ADDRESS OFFSET REGISTER - LOGICAL CHANNEL x. This register sets the offset, which is applied on the destination address after each line is written to memory. This register applies for both CCP2_LCx_DAT_PING_ADDR and CCP2_LCx_DAT_PONG_ADDR. For example, it enables 2D data transfers of the pixel data into a frame buffer. In such case, the pixel data and frame buffer data have the same data format. Note that the 5 LSBs are ignored: the offset shall be a multiple of 32 bytes. The use of this register is limited to the following data formats: YUV422 little-endian, YUV422 big-endian, RGB565, RGB444 + EXP16, RGB888 + EXP32. This register is shadowed; modifications are taken into account after the next FSC synchronization code. |                                                                                                                                                                                                                                                  |                 |           |
| <b>Type</b>             | RW                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                  |                 |           |

| <b>Description</b>      | Memory channel source offset register. This register sets the offset, which is applied on the source address after each line is read from memory. For example, it enables 2D data transfers of the pixel data from a frame buffer. In such case, the pixel data and frame buffer data have the same data format. The 5 LSBs are ignored; the offset is a multiple of 32 bytes. |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |                 |          |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| <b>Type</b>             | RW                                                                                                                                                                                                                                                                                                                                                                             |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |                 |          |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

| <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Memory channel destination offset register. This register sets the offset, which is applied on the destination address after each line is written to memory. For example, it enables 2D data transfers of the pixel data into a frame buffer. In such case, the pixel data and frame buffer data have the same data format. The 5 LSBs are ignored; the offset is a multiple of 32 bytes. |                                                                                                                                                                                                                                                                                                                                                       |      |            |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |          |  |  |

At the end of a line, only full 32-bit words are written, eventually creating gaps at the end of lines.<br>Otherwise, OFST sets the destination offset between the first pixel of the previous line and the first pixel of the current line. | RW   | 0x00000000 |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |          |  |  |

|-------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------|
| 31:16 | PPLN       | Pixels per line<br>Sets the number of pixel clock periods in one line. HD period = (PPLN + 1) pixel clocks. Not used when HS/VS sync pulses are input signals ( <a href="#">CCDC_SYN_MODE.VDHDOOUT = 0</a> ).<br>This bit field is latched by the VS sync pulse.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | RW   | 0x0000 |
| 15:0  | HLPFR      | Half line per field or frame<br>Sets the number of half lines per frame or field. VD period = (HLPFR + 1)/2 lines. Not used when HS/VS sync pulses are input signals ( <a href="#">CCDC_SYN_MODE.VDHDOOUT = 0</a> ).<br>Sets the internal timing generator to generate the correct number of HS pulses in between two VS pulses. If the sensor is interlaced, with a total of N lines, then this field must be set to N. This means that N half lines are written for each field. If the sensor is progressive, then this register must be set to be twice the number of lines to be written. For example, if sensor outputs N lines, this field must be set to 2N.<br>This bit field is latched by the VS sync pulse. | RW   | 0x0000 |

|-------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------|
| 31:16 | RESERVED   | Write Os for future compatibility.<br>Reads returns 0.                                                                                                                                                                                                                                                                                                                                                                                                                                             | RW   | 0x0000 |
| 15:0  | LNOFST     | Line offset.<br>Sets the offset for each output line to memory. The offset must be a multiple of 32 bytes: the 5 least significant bits are ignored. Usually the line offset is equal to the line length in bytes, that is, the line length must be a multiple of 32 bytes. If LNOFST = 0, the data is written again and again over the same line.<br>For optimal performance in the system, the address offset must be on a 256-byte boundary.<br>This bit field is latched by the VS sync pulse. | RW   | 0x0000 |

| 16    | FPERR      | <p>Fault pixel correction error<br/>           This bit is set when the CCDC module is unable to fetch the required fault pixel table entry in time. Write 1 to clear the error or end_of_frame clears it automatically for the next frame.</p> <p>For example, the current pixel being processed has coordinates of 256/512 (256th line and 512th pixel in that line) and it must be corrected. If the entry in the fault pixel table that must be used has coordinates 256/256, then the current pixel cannot be corrected since the correct entry is not loaded in time.</p> <p>Note that there is no error recovery mechanism in the CCDC; if this bit is set at anytime in a frame, there are no more fault pixels corrected in that frame. Firmware is responsible for making sure that there is enough bandwidth in the system to allow for loading of the fault pixel table. Alternately, decreasing the frequency of the fault pixels to be corrected enhances the chances of this bit not being set.</p> <p>0x0: No error<br/>           0x1: Error</p> | RW   | 0x0    |

| 15   | FPCEN      | <p>Fault pixel correction enable.<br/> Upon setting this bit, and as long as it remains enabled, the fault pixel logic continues to request data and just start over for next frame once the last data of current frame has been received. As soon as the register is set the data are fetched. To disable fault pixel correction, users can write a 0 at any time. However, the disabling only applies after the current frame is processed (busy bit for current frame is 0)<br/> This bit should only be written after the FPC_ADDR register below has been set. Also, the other fields in this register have to be set prior to enabling this bit. The required process is:<br/> Write(FPC_ADDR)<br/> Write(FPC) with this bit (FPC.FPCEN) turned off<br/> Write(FPC) with this bit (FPC.FPCEN) turned on while other fields are same as previous write</p> <p>0x0: Disable<br/> 0x1: Enable</p> | RW   | 0x0    |
| 14:0 | FPNUM      | <p>Number of fault pixels to be corrected in the frame<br/> This field should not be changed when the FPCEN is enabled at any time</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | RW   | 0x0000 |

|------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------|
| 31:0 | DRKF       | Dark frame address.<br>Specifies the dark frame start address in memory. The lower 5 bits of this register are always treated as 0s. The offset should be aligned on a 32-byte boundary.<br>This field can be altered even when the PREVIEW module is busy. The change takes place only for the next frame (next VS sync pulse). However, note that reading this register always gives the latest value. | RW   | 0x00000000 |

The only way to clear the overflow is to reset the bit. After an overflow, the data will be corrupted and the application layer should disregard the data. No software reset is required after an overflow. If the overflow condition is cleared the data will continue to be acquired normally. |         |   |   |   |   |   |   |  |  |  |          |  |  |  |  |  |  |  |  |  |  |  |  |

| 24   | CCDCPRV_2_RSZ_OVF | CCDC/PRV to RESIZER input overflow<br>This bit is set if the RESIZER input source is set to CCDC/PREVIEW engine when the active data (to be resized) has already showed up at the resizer interface. In such a case, resizing for this frame cannot take place and the bit is set. This scenario can happen when a resize of 4x is required per frame. Therefore, the RESIZER needs to operate in two passes. In the first pass the input data from CCDC/PREVIEW is directly resized and written to memory. In the second pass, the resized data from the first pass is resized again. The next frame from the CCDC/PREVIEW engine should only start after the second pass on the previous frame is complete. This bit indicates the failure status.<br>Software has to write 1 to clear the bit.<br><b>Note:</b> Ignore the behavior of this field when RSZ_CNT[28] INPSRC = 0x1 (when data comes from memory).<br>Read 0x0: No overflow<br>Read 0x1: Overflow | RW   | 0     |

| <b>Description</b>      | <p>DATA MEM ADDRESS OFFSET REGISTER - Context</p> <p>This register sets the offset, which is applied on the destination address after each line is written to memory. This register applies for both <a href="#">CSI2_CTX_DAT_PING_ADDR</a> and <a href="#">CSI2_CTX_DAT_PONG_ADDR</a>.</p> <p>For example, it enables to perform 2D data transfers of the pixel data into a frame buffer. In such case, the pixel data and frame buffer data shall have the same data format.</p> <p>Note that the 5 LSBs are ignored: the offset shall be a multiple of 32 bytes.</p> <p>This register is shadowed: modifications are taken into account after the next FSC sync code. Only full 32-bit values shall be written.</p> |                 |                                |

## Display Subsystem

This chapter describes the Display Subsystem for the device.

---

**NOTE:** This document is strictly for wireless/cellular software developers using AM/DM37x application processors, which are not available for the broad market through authorized distributors.

---

**NOTE:** This chapter contains information that is ©2005-2008 MIPI Alliance, Inc. All rights reserved. MIPI Alliance Member Confidential.

All rights reserved. This material is reprinted with the permission of the MIPI Alliance, Inc. No part(s) of this document may be disclosed, reproduced or used for any purpose other than as needed to support the use of the products of TI.

See [Device 37xx MIPI Disclaimer](#) for details.

---

**NOTE:** This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

## 7.1 Display Subsystem Overview

The display subsystem provides the logic to display a video frame from the memory frame buffer (either SDRAM or SRAM) on a liquid-crystal display (LCD) panel or a TV set. The display subsystem integrates the following elements:

- Display controller (DISPC) module
- Remote frame buffer interface (RFBI) module
- Display serial interface (DSI) complex I/O module and a DSI protocol engine
- DSI PLL controller that drives a DSI PLL and high-speed (HS) divider.
- NTSC/PAL video encoder

The display controller and the DSI protocol engine are connected to the L3 and L4 interconnect; the RFBI and the TV out encoder modules are connected to the L4 interconnect.

---

**NOTE:** The DSI complex I/O module, and the DSI PLL controller are not connected to an L3 or L4 interconnect. Specific display subsystem registers manage their programmable features.

---

Figure 7-1 shows a block diagram of the display subsystem.

**Figure 7-1. Display Subsystem Highlight**

**NOTE:** For more information about connecting the LOCK, RECAL, and TVINT signals through the GPIO2 and GPIO3 modules, see [Chapter 25, GPIO](#).

The display subsystem includes the following main features:

- Display controller
  - Display modes
    - Programmable pixel display modes (1, 2, 4, 8, 12, 16, and 24 bits-per-pixel [BPP] modes)
    - Programmable display size supported:

- XGA - 1024 x 768 VESA timings at 60 fps (pixel clock = 63.5 MHz)
- WXGA - 1280 x 800 VESA timings at 59.91 fps (pixel clock = 71 MHz)
- SXGA+ - 1400 x 1050 direct drive of LCD with minimal blanking at 50 fps (pixel clock = 75 MHz)
- HD 720p - 1280 x 720 at 60 fps (pixel clock = 74.25 MHz)
- 256 x 24-bit entries palette in red, green, and blue (RGB)
- Programmable pixel rate up to 75 MHz

---

**NOTE:** The panel size is programmable and can be any width that is a multiple of 8 pixels (line length) in the range [1:2048] pixels (in the case of the RFBI mode, the minimum transfer size is a byte). The maximum resolution is 2048 (lines) x 2048 (pixels).

---

- Display support
  - Four types of displays are supported: Passive (super-twist nematic [STN]) and active (thin-film transistor [TFT]) colors, passive (STN), and active (TFT) monochromes.
  - 4-/8-bit monochrome passive matrix panel interface support (15 grayscale levels supported using dithering block)
  - 8-bit color passive matrix panel interface support (3375 colors supported for a color panel using dithering block)
  - 12-/16-/18-/24-bit active matrix panel interface support (replicated or dithered encoded pixel values)
  - Remote frame buffer support through the RFBI module
  - Partial display through the RFBI module
  - Second 24-bit digital output
  - Multiple-cycle output format on 8-/9-/12-/16-bit interface time division multiplexing (TDM)
  - HDMI through external bridge
- Signal processing
  - Overlay support for graphics (ARGB, RGBA, RGB, or Color Look-Up Table (CLUT)) and video1 (YCbCr 4:2:2, RGB), video2 (YCbCr 4:2:2, or ARGB, RGBA, RGB)
  - Programmable video resizer independent horizontal and vertical resampling: Upsampling (up to x8) and downsampling (down to 1/4), maximum input width of 1024 pixels in 5-tap mode, and 2048 pixels in 3-tap configurations; no limitation on input height
  - Rotation 90-, 180-, and 270-degrees with DISPC DMA engine
  - Transparency color key (source and destination)
  - Synchronized buffer update
  - Programmable video color space conversion YCbCr 4:2:2 into RGB
  - Hardware cursor
  - Gamma curve support on LCD output
  - Multiple-buffer support
  - Mirroring support
  - Programmable color phase rotation (CPR)
  - Alpha blending support (no rescaling in ARGB or RGBA formats), with pre-multiplied alpha control
- Advanced
  - Self-refresh using the DMA FIFO
  - Arbitration between high/low priority (graphics video1 and video2)
  - FIFO handcheck in STALL mode
  - Power modes: Low-power saving modes
  - RFBI (MIPI® DBI protocol)

- Access to remote frame buffer (RFB) direct microprocessor unit (MPU) interface
  - Sends commands to the RFB panel through the L4 interconnect
  - Sends data, received from the display controller or from the MPU through the DISPC pixel data bus, to the RFB panel
  - Reads data/status from the RFB to the L4 interconnect
- RFB interface
  - 8-/9-/12-/16-bit 8086-series parallel interface
  - Two programmable configurations for two devices connected to the RFBI module
- Data formats
  - Programmable pixel modes (12-/16-/18-/24-BPP modes in RGB format)
  - Programmable output formats on one/multiple cycles per pixel (data from the display controller and from the L4 interconnect)
- Interconnect/FIFO
  - One slave port with DMA request and interconnect FIFO of 24x32-bit depth (for write access to DSS.[RFBI\\_DATA](#) register only)
  - One video port FIFO of 8 × 24-bit depth receiving data from the display controller
- MIPI DSI
  - Transfer pixels and data received on the video port or L4 interconnect to the display through the DSI DSI\_PHY
  - The maximum resolution supported on the video port is XGA at 60 fps with 24-bit pixels (maximum pixel clock of 67 MHz) for low voltage.
  - Supports video mode and command mode
  - Bidirectional data link support (only one data lane is used in reverse direction in command mode)
  - Supports up to two data-configurable lanes, in addition to the clock signaling (minimum of one data link and maximum of two, depending on speed, signal integrity requirements, and number of displays)
  - Maximum data rate of up to 900 Mbps per data pair
  - Data splitter for 2-data lane configuration
  - Error-correction code (ECC) and check-sum generation
  - Burst support for the video mode
  - RGB16, RGB18 packed and nonpacked, and RGB24 formats supported for video mode
  - Serial configuration port (SCP) for the DSI\_PHY complex I/O and DSI PLL
  - Connection to the DSI\_PHY complex I/O through PPI
  - Data interleaving support for one synchronous stream (video mode) from the display controller and up to three interleaved asynchronous streams (command mode) from the interconnect concurrently
  - Data interleaving supports up to four interleaved asynchronous streams (command mode) from the interconnect or video port when there is no video mode
  - MIPI DCS support (transparent to the protocol engine, no decoding and interpretation of the information from and to the peripheral)
  - Supports selection between low-power state and HS mode between HS packet transfers
  - Generic data type (DT) support

---

**NOTE:** The DSI pins are multiplexed with LCD parallel outputs.

---

- Video encoder
  - NTSC/PAL encoder outputs with the following standards:
    - NTSC-J, M
    - PAL-B, D, G, H, I

- PAL-M
- CGMS-A as described in the CEA-608-x Standard.
- Input data interface compatible with the following protocols:
  - 24-bit input bus compatible with external sync
  - RGB 4:4:4
- Dual output data 10-bit interface for two internal digital-to-analog converters (DACs) that support:
  - Composite video (CVBS)
  - Separate video (S-video)
- TV output data supports ITU-R BT 470-7 recommendation standard for consumer market
- Master clock input 13.5 MHz, 27 MHz (supports ITU-R 601 sampling for NTSC/PAL), and 54 MHz
- Programmable horizontal sync, vertical timing, and waveforms
- Programmable subcarrier frequency and SCH
- Internal test pattern generation (color bar, flat field, color burst)
- 2x/4x oversampling
- Supports square pixel sampling (NTSC: 12.27 MHz, 24.54 MHz, 49.09 MHz PAL: 14.75 MHz, 29.5 MHz, 59 MHz)

**CAUTION**

In square pixel mode, an external clock generator is required to provide sampling frequencies.

- TV detection gating pulse generation

## 7.2 Display Subsystem Environment

This section describes the two main functions handled by the display subsystem:

- LCD support
- TV display support

### 7.2.1 LCD Support

LCD panels can be connected to the display subsystem of the device using parallel and/or serial interfaces.

[Table 7-1](#) provides more details on the supported interfaces to LCD panels, and the respective pad and signal configurations.

Table 7-1. LCD Interface Signals and Configurations

|                                     |                   | Pads and Signals Configuration    |                                |                        |                                        |                                | Possible Operational Interfaces                                                        |                                                                                        |                                                                                          |
|-------------------------------------|-------------------|-----------------------------------|--------------------------------|------------------------|----------------------------------------|--------------------------------|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|

The DISPC\_DATA\_LCD[23:18] data is additionally multiplexed on the sys\_boot device pads to allow simultaneous availability of the DSI interface and the complete parallel 24-bit DSS interface.

---

**NOTE:** The DISPC\_DATA\_LCD[5:0] data multiplexed with the DSI signals on dss\_data[5:0] pads is limited to up to 60 MHz pixel clock frequency. If the parallel 18/24-bit interface in bypass mode with a pixel clock above 60 MHz is required, the DISPC\_DATA\_LCD[5:0] multiplexed on dss\_data[23:18] pads, and DISPC\_DATA\_LCD[23:18] multiplexed on sys\_boot pads must be used.

---

---

**NOTE:** Table 7-1 shows only the DSS capabilities of supporting simultaneous and sequential LCD interfaces due to the additional signal multiplexing, without describing explicitly all possible configurations.

---

For more information on signals multiplexing, see [Chapter 13, System Control Module](#). The parallel interface connectivity is detailed in [Section 7.2.1.1, Parallel Interface](#). For more details on the serial interface, see [Section 7.2.1.2, DSI Serial Interface](#).

### 7.2.1.1 Parallel Interface

In parallel interface, the paths of the display subsystem modules are the display controller and the RFBI.

The display controller provides the required control signals to interface the memory frame buffer (SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA (with embedded FIFOs) to read data from the system memory. The L3 interconnect is the master port, while the L4 interconnect is the slave port of the display subsystem.

The display controller has two I/O pad modes at the module level:

- RFBI mode (RFBI enabled), which implements the MIPI DBI 2.0 protocol
- Bypass mode (RFBI disabled), which implements the MIPI DPI 1.0 protocol

The DSS.[DISPC\\_CONTROL\[16:15\]](#) GPOUT[1:0] bits control selection of the display subsystem modules (see [Table 7-2](#)).

**Table 7-2. I/O Pad Mode Selection**

| DSS. <a href="#">DISPC_CONTROL[16]</a> GPOUT1 | DSS. <a href="#">DISPC_CONTROL[15]</a> GPOUT0 | Mode        |
|-----------------------------------------------|-----------------------------------------------|-------------|
| 0                                             | 0                                             | Reset       |
| 0                                             | 1                                             | RFBI mode   |
| 1                                             | 0                                             | Invalid     |
| 1                                             | 1                                             | Bypass mode |

The RFB of the LCD panel is connected directly to the RFBI module of the device. The RFBI controls the reads/writes from/to the RFB. The RFBI receives the output from the DISPC (which takes data from the memory) and generates the signals to control the LCD panel. Through the RFBI, the MPU can send commands or parameter/display data to the LCD panel and directly set the DISPC registers to read/write the data from/to the memory in the LCD panel. The RFBI can manage up to two LCD panels when the serial interface is not used.

#### 7.2.1.1.1 Parallel Interface in RFBI Mode (MIPI DBI Protocol)

[Figure 7-2](#) shows the LCD support parallel interface in RFBI mode (example for 16-bit data interface).

Figure 7-2. LCD Support Parallel Interface (RFBI Mode)

**NOTE:** Configure the DSS.RFBI\_CONTROL[3:2] CONFIGSELECT bit field to drive signals for LCD 1 only, LCD 2 only, or both LCD 1 and LCD 2.

Table 7-3 describes the interface signals to/from the LCD panel in RFBI mode.

Table 7-3. LCD Interface Signals (RFBI Mode)

| Signal Name    | Type <sup>(1)</sup> | Description                                                              |
|----------------|---------------------|--------------------------------------------------------------------------|
| RFBI_DA[15:0]  | I/O                 | RFBI I/O data                                                            |
| RFBI_RD        | O                   | Read access signal                                                       |
| RFBI_WR        | O                   | Write access signal                                                      |
| RFBI_A0        | O                   | Command/data selection signal                                            |

| RFBI_HSYNC1    | I                   | HSYNC from LCD panel 2                                                   |

<sup>(1)</sup> I = Input, O = Output

- RFBI\_DA[15:0]: The pixel data comprises the RFBI pixel data (bits 15:0). A write/read command must be sent to the LCD panel to send/read the data.  
Before any data access, the application must send commands and parameters when it is necessary to configure an LCD panel. The data is used as input in read operations during production test and also to read the status of the registers in the LCD panel and pixels from the embedded frame buffer in the LCD panel module. RFBI\_DA is multiplexed at the chip-level boundary with dss\_data [15:0].
- RFBI\_RD: This is the read-enable signal used to indicate when a read from the embedded memory in the LCD panel is ongoing. The RFBI registers describe the behavior of the read signal (off/on/cycle).

time). The polarity of the read-enable signal is programmable. This signal is multiplexed at the chip-level boundary with dss\_pclk. The read is used to get status/data information from the LCD panel.

- RFBI\_WR: The write-enable signal is used to indicate when a write is ongoing. The RFBI registers describe the behavior of the write signal (off/on/cycle time). The polarity of the write-enable signal is programmable. This signal is multiplexed at the chip-level boundary with dss\_vsync.
- RFBI\_A0: The signal is asserted to indicate its status: Command or data. The polarity is programmable and the status of the signal depends on the RFBI registers written by the application (CMD/READ/STATUS/PARAM/PIXEL). The register in use by the hardware defines the status of RFBI\_A0. The order of the writes/reads to the RFBI registers CMD/READ/STATUS/PARAM/PIXEL defines the transitions of A0. This signal is multiplexed at the chip-level boundary with dss\_acbias.
- RFBI\_CSx: The signal is the chip-select (CSx) asserted to indicate which LCD panel is selected and must be ready to receive/transmit commands and data. When RE or WE is on, CSx must not be changed ( $x = 0$  for LCD panel 1;  $x = 1$  for LCD panel 2). CS0 is multiplexed at the chip-level boundary with dss\_hsync, and CS1 is multiplexed at the chip-level boundary with dss\_data[20].
- RFBI\_TE\_VSYNCx: Based on the trigger mode selected, the signal is the TE pulse signal or the LCD panel VSYNC (vertical synchronization) pulse signal. RFBI\_TE\_VSYNCx is used by the TE logic as the synchronization signal to send the pixel to the LCD panel.

To select the trigger mode, configure the DSS.[RFBI\\_CONFIG\[3:2\]](#) TRIGGERMODE bit field (0x0: Internal trigger mode with the DSS.[RFBI\\_CONTROL\[4\]](#) ITE bit, 0x1: External trigger mode with the TE signal RFBI\_TE\_VSYNCx, 0x2: External trigger mode with the RFBI\_TE\_VSYNCx, and RFBI\_HSYNCx signals with the programmable line counter).

These signals are multiplexed at the chip-level boundary with dss\_data[16] (RFBI\_TE\_VSYNC0) and dss\_data[18] (RFBI\_TE\_VSYNC1) (LCD panel 1:  $x = 0$ ; LCD panel 2:  $x = 1$ ).

- RFBI\_HSYNCx: The HSYNC pulse signals indicate to the RFBI module when horizontal synchronization occurs. The polarity of the HSYNC signals is programmable. The minimum pulse width of the signal is two L4 cycles. RFBI\_HSYNC is used by the TE logic as a synchronization signal to send the pixel to the LCD panel. These signals are multiplexed at the chip-level boundary with dss\_data[17] (RFBI\_HSYNC0) and dss\_data[19] (RFBI\_HSYNC1) (LCD panel 1:  $x = 0$ ; LCD panel 2:  $x = 1$ ).

#### 7.2.1.1.1 Description of the TE Pulse Signal

The externally-generated TE synchronization signal is a logical OR or AND operation between the HSYNC and VSYNC signals (see [Figure 7-3](#)). The logical operation (OR or AND) depends on the HSYNC and VSYNC signals polarity. The VSYNC signal indicates to the RFBI module when vertical synchronization occurs; the HSYNC signal indicates to the RFBI module when horizontal synchronization occurs.

**Figure 7-3. External Generation of TE Signal Based on Logical OR Operation Between HSYNC and VSYNC (Active-High)**

The RFBI module detects the VSYNC and HSYNC pulses embedded in the received signal. VSYNC is detected based on the minimum pulse width defined by the DSS.[RFBI\\_VSYNC\\_WIDTH](#) register.

HSYNC is detected based on the minimum pulse width defined by the DSS.[RFBI\\_HSYNC\\_WIDTH](#) register.

The signal is generated from external logic based on the VSYNC/HSYNC of the LCD panel. The automatic trigger can be programmed based on the RFBI\_TE signal or use a bit field in the RFBI registers to start data capture.

The polarity of the TE signal is programmable. The HSYNC and VSYNC pulses embedded in the TE signal have the same polarity, which is active high for an ORed signal and active low for an ANDed signal. The minimum pulse width of the signal is two L4 cycles. Hardware resets the line counter when the VSYNC occurs and increments it at every HSYNC. Transfer to the LCD panel begins when the line counter reaches the programmable line number.

#### 7.2.1.1.2 Parallel Interface in Bypass Mode (MIPI DPI Protocol)

When bypass mode is enabled, the display controller must be set to use it.

[Figure 7-4](#) shows the LCD support parallel interface in bypass mode.

**Figure 7-4. LCD Support Parallel Interface (Bypass Mode)**

[Table 7-4](#) describes the interface signals to/from the LCD panel in bypass mode.

**Table 7-4. LCD Interface Signals (Bypass Mode)**

| Signal Name          | Type <sup>(1)</sup> | Description                                  |
|----------------------|---------------------|----------------------------------------------|
| DISPC_DATA_LCD[23:0] | O                   | LCD data from the display controller module  |
| DISPC_PCLK           | O                   | Pixel CLK from the display controller module |
| DISPC_VSYNC          | O                   | VSYNC from the display controller module     |
| DISPC_HSYNC          | O                   | HSYNC from the display controller module     |
| DISPC_ACBIAS         | O                   | ACBIAS from the display controller module    |

<sup>(1)</sup> I = Input, O = Output, I/O = Input/Output

- DISPC\_DATA\_LCD[23:0]: The panel pixel data comes directly from the display controller module. DISPC\_DATA\_LCD is connected at the chip-level boundary with dss\_data[23:0].
- DISPC\_PCLK: This signal is the pixel clock that comes directly from the display controller. This signal is multiplexed at the chip-level boundary with dss\_pclk.
- DISPC\_VSYNC: Uses the vertical synchronization signal from the display controller. The LCD frame clock (VSYNC) toggles after all the lines in a frame are transmitted to the LCD panel and a programmable number of line clock cycles has elapsed both at the beginning and at the end of each frame. This signal is multiplexed with dss\_vsync at the chip-level boundary.
- DISPC\_HSYNC: Uses the horizontal synchronization signal from the display controller. The LCD line clock (HSYNC) toggles after all pixels in a line are transmitted to the LCD panel and a programmable number of pixel clock wait-states elapse, both at the beginning and at the end of each line. This signal is multiplexed on the chip-level boundary with dss\_hsync.
- DISPC\_ACBIAS: Uses the ac-bias signal from the display controller.

- In passive matrix technology, the ac-bias signal is configured to transition each time a programmable number of line clocks occurs. To prevent a dc charge within the screen pixels, the power and ground supplies of the panel are periodically switched. The DISPC signals the panel to switch the polarity by toggling the ac-bias pin.
- In active matrix technology, the ac-bias signal acts as an output-enable signal to indicate when data must be latched using the pixel clock. This signal is multiplexed on the chip-level boundary with dss\_acbias.

#### 7.2.1.1.3 LCD Output and Data Format for the Parallel Interface

This section describes the pixel data bus and shows timing diagrams of transactions and synchronizations in both RFBI and bypass modes.

Figure 7-5 through Figure 7-11 show the pixel data bus for bypass mode, depending on the use of 4-, 8-, 12-, 16-, 18-, or 24-pixel data output pins. In RFBI mode, the pixel data bus is reformatted in accordance with the input and output data bus width.

Table 7-5 lists the number of displayed pixels per pixel clock cycle based on the type of display panel.

**Table 7-5. Number of Displayed Pixels per Pixel Clock Cycle Based on Display Type**

| Display Panel        | Number of Displayed Pixels per Pixel Clock Cycle |
|----------------------|--------------------------------------------------|
| Monochrome 4-bit     | 4                                                |
| Monochrome 8-bit     | 8                                                |
| Passive matrix color | 8/3                                              |
| Active matrix        | 1                                                |

- Passive matrix technology, Monochrome mode

Monochrome displays use either a 4-bit or 8-bit interface. Each bit represents one pixel (on or off), which means that either 4 or 8 pixels are sent to the LCD at each pixel clock.

Figure 7-5 and Figure 7-6 show 4- and 8-bit monochrome displays, respectively.

**Figure 7-5. LCD Pixel Data Monochrome4 Passive Matrix**

**Figure 7-6. LCD Pixel Data Monochrome8 Passive Matrix**

- Passive matrix technology, color mode

Color passive displays use 8-bit data input lines. In a given pixel clock cycle, each line represents one color component (red, green, or blue).

[Figure 7-7](#) shows an 8-bit color passive matrix display.

**Figure 7-7. LCD Pixel Data Color Passive Matrix**

- Active matrix technology

Active matrix displays bypass the STN dithering logic block and the output FIFO. Each line represents one pixel.

[Figure 7-8](#) through [Figure 7-11](#) show 12-, 16-, 18-, and 24-active matrix displays, respectively.

**Figure 7-8. LCD Pixel Data Color12 Active Matrix**

**Figure 7-9. LCD Pixel Data Color16 Active Matrix****Figure 7-10. LCD Pixel Data Color18 Active Matrix**

**Figure 7-11. LCD Pixel Data Color24 Active Matrix**

dss-011

#### 7.2.1.1.4 Transaction Timing Diagrams

- Timing diagrams in flow control mode
  - Stall signal

The stall signal is used in RFBI and DSI modes. In the case of RFBI mode, it is used to indicate when the display controller must stop sending data over the LCD output interface. The RFBI module asserts the stall signal to stop data output by the display controller. It is deasserted to indicate when new data must be outputted by the display controller.

**Figure 7-12. RFBI Data Stall Signal Diagram**

dss-134

To avoid underflow of the DMA FIFO, the FIFO handcheck feature can be enabled by setting the DSS.DISPC\_CONFIG[16] FIFOHANDCHECK bit to 1. The fullness of the FIFOs associated with the pipelines used for the LCD output is checked when the STALL signal is inactive before providing data to the pipeline. This prevents emptying the FIFO when the RFBI module requests data and there is not enough data in the display controller DMA FIFO. This feature must be enabled only when the STALL mode is used (DSS.DISPC\_CONTROL[11] STALLMODE bit set to 1).

When the FIFO handcheck feature is activated, the pixel transfer to the RFBI module during STALL inactivity period can be stopped (no DISPC\_PCLK pulse) and restarted when there is enough data in the FIFO. The FIFO handcheck ensures that underflow cannot occur for the pipelines associated with the LCD output in RFBI mode. Figure 7-13 details the RFBI data stall with FIFO handcheck mode activated.

**Figure 7-13. RFBI Data Stall Signal Diagram With Handcheck**

- RFBI timing diagrams

Table 7-6 lists the programmable timing fields. Figure 7-14 through Figure 7-16 show timing diagrams of read/write transactions to the LCD panel for the RFBI mode.

**Table 7-6. Programmable Timing Fields in RFBI Mode**

| Timing Name  | Register Field                                                     | Description                                                 |
|--------------|--------------------------------------------------------------------|-------------------------------------------------------------|
| CSOnTime     | DSS.RFB1_ONOFF_TIMEi[3:0]<br>CSONTIME (with $i = 0$ or $1$ )       | CS assertion time from start access time                    |

| Signal Name | I/O <sup>(1)</sup> | Description | Value at Reset |  |
|-------------|--------------------|-------------|----------------|--|
| dsi_dy2     |                    |             |                |  |

**NOTE:** Each serial line (line 1, line 2, and line 3) can be used as clock lane or data lane. All polarities are supported. The MIPI DSI 1.0 protocol requires at least one clock line and one data lane.

Lanes support four operating modes:

- HS mode: High-speed transmit mode
- LP mode: Low-power transmit mode (also called low-power state [LPS])
- ULPS: Ultra-low power state used between two transmissions
- Off mode: Lane is off.

#### 7.2.2.1.1 Data/Clock Configuration

From the device point of view, the DSI interface consists of six input/output signals representing three differential signals: The serial clock and one or two serial data. The minimum configuration is one data pair and one clock pair.

- The data signal carries the bit-serial data. The DSI transmitter in the host sends the data in-quadrature with the DDR clock in high speed mode; otherwise, the clock is extracted from the received data in low-speed mode. The data is transmitted byte-wise least significant bit (LSB) first.
- The clock signal carries the DDR clock signal in high speed transmission.
- Software users must configure the order of the data lanes to indicate the byte order while splitting the byte stream for each DSI\_PHY into bytes.

Table 7-9 details all the DSI lanes configuration.

**Table 7-9. DSI Lane Configuration**

| DSI DSI_PHY Lane Configuration | Data/Clock Lane Position |          |          | Description      |
|--------------------------------|--------------------------|----------|----------|------------------|
|                                | 1                        | 2        | 3        |                  |
| Mode CLK + DATA1               | CLK                      | DATA1    | Not used | Single data lane |
|                                | CLK                      | Not used | DATA1    |                  |
|                                | DATA1                    | CLK      | Not used |                  |
|                                | Not used                 | CLK      | DATA1    |                  |
|                                | DATA1                    | Not used | CLK      |                  |
|                                | Not used                 | DATA1    | CLK      |                  |
| Mode CLK + DATA1 + DATA2       | CLK                      | DATA1    | DATA2    | Two data lanes   |
|                                | CLK                      | DATA2    | DATA1    |                  |
|                                | DATA1                    | CLK      | DATA2    |                  |
|                                | DATA2                    | CLK      | DATA1    |                  |
|                                | DATA1                    | DATA2    | CLK      |                  |
|                                | DATA2                    | DATA1    | CLK      |                  |

**NOTE:**

- The byte on D<sub>n</sub> is sent before the byte on D<sub>n+1</sub>, all the combinations of data and clock are supported through programming of the DSS.[DSI\\_COMPLEXIO\\_CFG1](#) register. The CLOCK\_POSITION and CLOCK\_POL bit fields configure which lane transmits the clock and define its polarity. Four bit fields (DATA1\_POSITION, DATA1\_POL, DATA2\_POSITION, and DATA2\_POL) configure the data lanes and their polarity. The DATA2\_POSITION bit field can be set to 0; in this case, only the data lane defined in the DATA1\_POSITION bit field is used, and data is transmitted on only one clock lane and one data lane.
- The configuration of the DSI complex I/O (number of data lanes, position, differential order) must not be changed while DSS.[DSI\\_CLK\\_CTRL\[20\]](#) LP\_CLK\_ENABLE bit is set to 1. For the hardware to recognize a new configuration of the complex I/O (done in DSS.[DSI\\_COMPLEXIO\\_CFG1](#) register), it is recommended to follow this sequence: First set the DSS.[DSI\\_CTRL\[0\]](#) IF\_EN bit to 1, next reset the DSS.[DSI\\_CTRL\[0\]](#) IF\_EN to 0, then set DSS.[DSI\\_CLK\\_CTRL\[20\]](#) LP\_CLK\_ENABLE to 1, and finally, set again the DSS.[DSI\\_CTRL\[0\]](#) IF\_EN bit to 1. If the sequence is not followed, the DSI complex I/O configuration is undetermined.
- Only DATA1 is bidirectional in command mode. The low-power received information is always sent by the display panel using DATA1. Since any lane of the DSI complex I/O can be configured as data lane DATA1, all lanes of the complex I/O are bidirectional

### 7.2.2.1.2 ULPS

Each lane can be put in ultra-low power state (ULPS) by software configuration. The ULPS mode requires all the following conditions:

- The lane must be in stop state.
- For data lanes, no data must be pending in the DSI module.
- For data lane 1, no BTA should have been sent. The DSI module should have control of the bus.

The control of each lane is independently controlled by the DSS.[DSI\\_COMPLEXIO\\_CFG2](#) register.

### 7.2.2.2 Video Port (VP) Interface

**NOTE:** The signals described in this section are internal and not bounded outside the device. This section aims at helping software users understand the internal connections between the display controller (DISPC) and the DSI protocol engine.

[Table 7-10](#) summarizes the video interface signals. This interface is used to connect the display controller to the DSI protocol engine to send real time data streams. Note that only the active matrix timings are supported by DSI protocol engine. The HSYNC/VSYNC/DE/DATA signals are driven on the rising or falling edge of the pixel clock (VP\_PCLK).
