**Table 7-10. Video Interface for DSI Protocol Engine**

| Signal Name   | Type <sup>(1)</sup> | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VP_HSYNC      | I                   | Horizontal sync signal                                                                                                                                                                                                                                                                                                                                                                                                                |
| VP_VSYNC      | I                   | Vertical sync signal                                                                                                                                                                                                                                                                                                                                                                                                                  |
| VP_DATA[23:0] | I                   | Parallel output data: Bits 0 to 23                                                                                                                                                                                                                                                                                                                                                                                                    |
| VP_PCLK       | I                   | Pixel clock. In case of STALL configuration, it is used to indicate when new data is on the data bus during the clock period of VP_CLK. The VP_PCLK is generated from VP_CLK through division. The clock ratio is defined in the DSS. <a href="#">DSI_CTRL[4]</a> VP_CLK_RATIO bit and must be aligned with the configuration of the clock divisor in the display controller (DSS. <a href="#">DISPC_DIVISOR[7:0]</a> PCD bit field). |
| VP_DE         | I                   | Data enable                                                                                                                                                                                                                                                                                                                                                                                                                           |

<sup>(1)</sup> I = Input, O = Output

**Table 7-10. Video Interface for DSI Protocol Engine (continued)**

| Signal Name | Type <sup>(1)</sup> | Description                                                                                                                                                                                                                 |
|-------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VP_STALL    | O                   | The stall signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in STALL mode; in that mode, HSYNC and VSYNC are not generated). |
| VP_CLK      | I                   | Display controller internal clock. It is a free-running clock.                                                                                                                                                              |

**NOTE:**

- The polarities of VP\_HSYNC and VP\_VSYNC are programmable by setting the DSS.DSI\_CTRL register.
- The maximum frequency for VP\_CLK is 173 MHz at nominal voltage, and 96 MHz at low voltage.
- Clocks VP\_CLK and VP\_PCLK can have the same frequency.
- The number of bits to be captured on the video port is defined in the DSS.DSI\_CTRL[7:6] VP\_DATA\_BUS\_WIDTH bit field.
- VP\_DE is connected to the dss\_acbias signal in the display controller, and its polarity can be controlled by setting the DISPC\_POL\_FREQ[15] IEO bit.

The data received on the video port can be stored into the line buffer memories or sent directly on the DSI interface in two cases:

- The line buffer size is too small compared to the line from the display controller.
- There is no line buffer instantiated. If there is no line buffer, the burst mode, defined as frequency burst mode, cannot be used. Only the transparency burst mode is supported.

**NOTE:** The DSS.DSI\_CTRL[13:12] LINE\_BUFFER bit field defines the number of lines to be used for transferring data from the video port to the DSI link.

**7.2.2.2.1 Video Port Used for Video Mode**

If the video port is used for video mode, the VP\_STALL is not used. **Table 7-11** lists the active signals on the video port.

**Table 7-11. Video Interface in the Context of Video Mode**

| Signal Name   | Type <sup>(1)</sup> | Description                                                                                                                                                 |
|---------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VP_HSYNC      | I                   | Horizontal sync signal                                                                                                                                      |
| VP_VSYNC      | I                   | Vertical sync signal                                                                                                                                        |
| VP_DATA[23:0] | I                   | Parallel output data: bits 0 to 23                                                                                                                          |
| VP_PCLK       | I                   | Pixel clock.                                                                                                                                                |
| VP_DE         | I                   | Data enable                                                                                                                                                 |
| VP_CLK        | I                   | It is a free running clock used as the display controller functional clock. The maximum frequency is 173 MHz at nominal voltage, and 96 MHz at low voltage. |

<sup>(1)</sup> I = Input, O = Output

Three video modes are available:

- No line buffer: The data received on the video port are directly output of the DSI port without buffering. The ratio of VP\_CLK and the DSI high-speed (HS) clock period must ensure identical throughput on the two ports (the two clocks must be generated using the same PLL; the subsystem must provide such configuration).
- One line buffer:
  - The data are first stored in the line buffer; once all the data for one line are received, the DSI protocol engine sends the whole line. The software must adjust timings to allow for the storage of all line data into the line buffer before sending to DSI outputs. The synchronization packets are never stored into the line buffer.

- Two line buffers:
  - One line is stored when the second line is output on the DSI port. It allows burst capability. While receiving the first line of the frame, there is no RGB packets sent because the line buffers are empty. To send the last line of the frame, a dummy line must be provided by the display controller to flush the line buffers. The synchronization packets are never stored into the line buffer.

---

**NOTE:** If more active lines are received on the video port than the number defined in the DSS.DSI\_VM\_TIMING3[15:0] VACT bit field, the extra lines are discarded by the DSI protocol engine. These lines are treated as blanking lines.

---

Figure 7-34, Figure 7-35, and Figure 7-36 show these three video modes.

**Figure 7-34. DSI Video Mode Without Burst (No-Line Buffer)**

**Figure 7-35. DSI Video Mode Without Burst (One-Line Buffer)**

dss-137

**Figure 7-36. DSI Video Mode With Burst (Two-Line Buffers)**

dss-138

**NOTE:** In [Figure 7-34](#), [Figure 7-35](#), and [Figure 7-36](#):

- When HSync start and Hsync end short packets are not generated (HSA does not exist), HBP signal must be different from 0.
- The software must ensure that VBP is always defined so that there is at least one HSYNC during VBP.
- In blanking low-power mode (BL-LP), two options are possible
  - The lane remains in ULPS, and the [DSI\\_CTRL\[20\]](#) BLANKING\_MODE bit is set to 0x0.
  - Dummy bytes are sent during LP with the [DSI\\_CTRL\[20\]](#) BLANKING\_MODE bit set to 0x1; the number of sent bytes is determined by the [DSI\\_VM\\_TIMING6\[15:0\]](#) BL\_LP\_INTERLEAVING bit field.

If the signal VP\_DE is not asserted during enough VP\_PCLK cycles to be able to capture the number of bytes defined in the word count of the header, the module must send the valid data received on the video port followed by bytes of 0s to match the required number of bytes to transmit. The VP\_PCLK must be present during all extra cycles where the DSI protocol engine is expecting pixels.

If the VP\_DE signal is asserted for too many VP\_PCLK cycles, the module should stop capturing the data on the video port while the number of bytes to capture, as defined in the word count field of the header, is reached.

The HS must check that the received synchronization events on the video port (VSYNC and HSYNC) are within the synchronization window based on expected timings. If the timings (internal and received) are out of sync, the interrupt for out-of-sync must be generated and the interface must be disabled ([DSS.DSI\\_CTRL\[0\]](#) IF\_EN bit is automatically reset by hardware). The unsynchronization window is defined by the [DSS.DSI\\_VM\\_TIMING2\[27:24\]](#) WINDOW\_SYNC bit field.

#### 7.2.2.2 Video Port Used on Command Mode

If the video port is used for command mode, the VP\_HSYNC, VP\_VSYNC, and VP\_DE signals are not used. [Table 7-12](#) describes the active signals on the video port.

**Table 7-12. Video Interface in the Context of Command Mode**

| Signal Name   | Type <sup>(1)</sup> | Description                                                                                                                                                                                                                 |
|---------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VP_DATA[23:0] | I                   | Parallel output data: bits 0 to 23                                                                                                                                                                                          |
| VP_PCLK       | I                   | One pulse is generated every time new data is output on the data bus                                                                                                                                                        |
| VP_STALL      | O                   | The stall signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in STALL mode; in that mode, HSYNC and VSYNC are not generated). |
| VP_CLK        | I                   | Display controller internal clock: It is a free running clock used as the display controller functional clock. The maximum frequency is 173 MHz at nominal voltage and 96 MHz at low voltage.                               |

<sup>(1)</sup> I = Input, O = Output

**NOTE:** The stall signal must be deasserted to receive pixels and asserted to stop receiving pixels.

[Figure 7-37](#) and [Figure 7-38](#) show the VP\_STALL signal assertion and deassertion on rising and falling edges, respectively.

**NOTE:** In DSI command mode, the display controller must be configured in stall mode by setting the [DSS.DISPC\\_CONTROL\[11\]](#) STALLMODE bit to 1.

**Figure 7-37. Stall Timing With Pixel on Rising Edge**

dss-187

**Figure 7-38. Stall Timing With Pixel on Falling Edge**

dss-188

To stop the transfer, the VP\_STALL signal must be asserted when the last data is output. The data can be output on the rising or falling edge of the VP\_PCLK through registers in the display controller module. The case with data output on falling edge of VP\_PCLK is supported by the DSI protocol engine.

The VP\_PCLK clock is generated from VP\_CLK; these two clocks are balanced. Assertion and deassertion of VP\_PCLK is done on the rising edge of VP\_CLK. The width of the VP\_PCLK pulse depends on the configuration of the clock divisor in the display controller (DSS.DISPC\_DIVISOR[7:0] PCD bit field). In the DSI protocol engine, the information is defined in the DSS.DSI\_CTRL[4] VP\_CLK\_RATIO bit and must be aligned with the display controller configuration.

Deassertion of the VP\_STALL signal must occur at least 4 VP\_CLK cycles before assertion of VP\_PCLK. Assertion of VP\_STALL must occur one cycle VP\_CLK after deassertion of VP\_PCLK for the last pixel to be transferred. The VP\_CLK clock is generated by the display controller under software control. It can be kept running between assertion and deassertion of VP\_STALL.

The word count (WC) defined in the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register for the virtual channel (VC) associated with the video port, indicates the number of bytes to receive (one line or two lines can be used, depending on the WC and size of the line buffer). The total size defined in the WC of the header register cannot exceed the size of the line buffer multiplied by the number of buffer lines.

The stall assertion/deassertion depends on the number of bytes to be received considering the size of the video port bus defined in the DSS.DSI\_CTRL[7:6] VP\_DATA\_BUS\_WIDTH bit field.

Figure 7-39 shows the data flow in command mode using the video port.

**Figure 7-39. Data Flow in Command Mode Using the Video Port**

dss-139

Two command modes are available:

- One line buffer: The data are stored in the line buffer before being sent.
- Two line buffers: The two lines are used if the word count defined in the [DSS.DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#) register is bigger than the line size; otherwise, one line buffer is used.

---

**NOTE:** In command mode, the video port can only be used in one or two line buffer configuration. The no-line buffer configuration is not allowed.

---

The packets can be sent using high-speed or low-speed.

---

**NOTE:** The DCS command in the payload can be inserted automatically using the [DSI\\_CTRL\[24\]](#) DCS\_CMD\_ENABLE bit. If TE is used, hardware automatically inserts the DCS Write Start command for the first packet of the frame transfer and the DCS Write Continue command for all subsequent packets.

---

#### 7.2.2.2.3 Burst Mode

When the burst mode is enabled, the video port receives data from the display controller at the pixel clock. The DSI protocol engine buffers the data in its own line FIFO (double-line buffer of 1024 x 24-bit pixels maximum). The read speed of the line can be twice the pixel clock to increase the blanking time of the video mode and to allow command mode traffic to be interleaved during the blanking period. The burst mode uses a dual-line buffer.

The DSI port can output data from one line buffer while the second one is accessed by the video port. The two processes are concurrent but they do not access the same line at the same time. The DSI transfer can start only when the whole video port line is transferred into a line buffer. The switch is controlled by the VP\_HS signal on the video port side and by internal signal on the DSI port indicating that the last data for the current line has been written into the line buffer.

---

**NOTE:** The line buffers are used to store the pixels only. The synchronization codes are not stored in the line buffers. They must be sent according to the video port timings.

---

### 7.2.2.3 Multilane Layer

Peripherals do not typically have high bandwidth requirements for returning data to the host processor. To keep designs simple and improve interoperability, all DSI-compliant systems must use only Lane 1 in LP mode for returning data from a peripheral to the host processor.

#### 7.2.2.3.1 SoT and EoT in Multilane Configurations

Since a HS transmission is composed of an arbitrary number of bytes that may not be an integer multiple of the number of lanes, some lanes may run out of data before others. Therefore, the lane management layer, as it buffers up the final set of less-than-N bytes, deasserts its valid data signal into all lanes for which there is no further data. Although all lanes start simultaneously with parallel SoTs, each lane operates independently and may complete the HS transmission before the other lanes, sending an EoT one cycle (byte) earlier.

#### 7.2.2.3.2 Lane Splitter

The lane splitter can split the byte stream into 2 lanes (for 1 lane, the splitter is bypassed). Figure 7-40 and Figure 7-41 show the byte position into each serial link for 1 and 2 data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to send and the number of lanes. The splitter module is only used when packets are sent using high-speed mode (HS). In low-power mode (LP), only one data lane is used (Lane 1).

**Figure 7-40. Two Data Lane Configuration**

ds-140

**Figure 7-41. One Data Lane Configuration**

ds-329

In case of back-to-back packets, the byte stream is considered as a single packet by the splitter module. Figure 7-42 shows the example of two packets sent back to back. N bytes for the first packet and M bytes for the second one.

**Figure 7-42. Two Packets Using Two-Data Lane Configuration (Example)**

dss-142

#### 7.2.2.4 Protocol Layer

The low level protocol (LLP) is a byte-oriented protocol. It supports short and long packet formats. The DSI protocol layer defines how the display data is transported onto the physical layer. Packets can be sent using high-speed or low-speed mode. LLP is selected through DSI registers. The features of the DSI protocol layer are:

- Transport of arbitrary data (payload independent)
- 8-bit word size
- Support for up to four interleaved VCs on the same link
- Special packets for frame start, frame end, line start, and line end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- ECC for 1-bit or 2-bit error detection in the header
- 16-bit checksum code for error detection

Figure 7-43 shows the protocol layer with short and long packets.

**Figure 7-43. Protocol Layer With Short and Long Packets**

**Key:**

|                           |                         |
|---------------------------|-------------------------|
| ST: Start of transmission | ET: End of transmission |
| PH: Packet header         | PF: Packet footer       |
| LPS: Low-power state      | SP: Short packet        |

dss-143

##### 7.2.2.4.1 Short Packet

Figure 7-44 shows the structure of the short packet. A short packet must contain an 8-bit data ID followed by two command or data bytes and an 8-bit ECC; a packet footer must not be present. Short packets must be 4 bytes in length. The ECC byte allows correction of single-bit errors and detection of 2-bit errors in the short packet.

**Figure 7-44. Short Packet Structure**

**NOTE:** The short packets can be sent in low-power mode or in high-speed mode.

#### 7.2.2.4.2 Long Packet

Figure 7-45 shows the structure of the low-level protocol long packet. A long packet must consist of three elements: A 32-bit packet header (PH), an application-specific data payload with a variable number of bytes, and a 16-bit packet footer (PF). The packet header is further composed of three elements: An 8-bit data identifier, a 16-bit word count, and 8-bit ECC. The packet footer has one element, a 16-bit checksum. Long packets can be from 6 to 65,541 bytes in length.

**Figure 7-45. Long Packet Structure**

- The data identifier defines the VC for the data and the DT for the application-specific payload data.
- The word count defines the number of bytes in the data payload between the end of the packet header and the start of the packet footer. Neither the packet header nor the packet footer must be included in the word count.
- The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the packet header. This includes the data identifier and the word count fields.

After the end of the packet header, the receiver reads the next word count \* bytes of the data payload. There are no limitations on the value of a data word within the data payload block, that is, no embedded codes are used. Once the receiver has read the data payload, it reads the checksum in the packet footer. Peripherals are not required to calculate a checksum. Also note the special case of zero-byte data payload: If the payload has length 0, then the checksum calculation results in (0xFFFF). If the checksum is not calculated, the packet footer must consist of 2 bytes of all zeros (0x0000). In the generic case, the length of the data payload must be a multiple of bytes. In addition, each data format may impose additional restrictions on the length of the payload data, that is, multiple of 4 bytes. Each byte is transmitted LSB first. Payload data may be transmitted in any byte order, restricted only by data format requirements. Multibyte elements such as word count and checksum must be transmitted least-significant byte first.

**NOTE:** The long packets can be sent in low-power mode or high-speed mode.

#### 7.2.2.4.3 Data Identifier

The data identifier byte contains the virtual VC ID value and the DT value, as shown in [Figure 7-46](#). The VC ID is contained in the 2 MSBs of the data identifier byte. The DT value is contained in the 6 LSBs of the data identifier byte. DI[7:6]: These 2 bits identify the data as directed to one of four VCs. DI[5:0]: These six bits specify the DT.

**Figure 7-46. Data Identifier Structure**

dss-146

#### 7.2.2.4.4 Virtual Channel ID - VC Field, DI[7:6]

The host can service up to four peripherals with tagged commands or blocks of data using the VC ID field of the header for packets targeted at different peripherals. The VC ID enables one serial stream to service two or more virtual peripherals by multiplexing packets onto a common transmission channel. Note that each packet sent in a single transmission have its own VC assignment and can be directed to different peripherals. The VC ID is defined in the DSS.[DSI\\_VCn\\_SHORT\\_PACKET\\_HEADER](#) and DSS.[DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#) registers for short and long packets, respectively. It should not be modified by hardware. There is one set of registers for each VC. Each set of registers defines the characteristics of the traffic between the host and the display associated with the VC.

[Figure 7-47](#) shows the VC controller.

**Figure 7-47. Virtual Channel Controller**

dss-147

#### 7.2.2.4.5 Data Type Field DT[5:0]

The DT field specifies whether the packet is a long or short packet type and the packet format. The DT field, along with the word count field for long packets, informs the receiver on how many bytes to expect in the remainder of the packet. This is necessary because there are no special packet start/end sync codes to indicate the beginning and end of a packet. This permits packets to convey arbitrary data, but it also requires the packet header to explicitly specify the size of the packet.

#### 7.2.2.4.6 Pixel Data Formats in Video Mode

The host can send different pixel formats in video mode. [Table 7-13](#) summarizes the pixel formats supported by the DSI interface in video mode.

**Table 7-13. Pixel Data Format in Video Mode**

| Mode                                          | Description   |
|-----------------------------------------------|---------------|
| RGB888 (using 24-bit container)               | RGB888        |
| RGB666 (using 24-bit container)               | RGB666        |
| RGB666 (18-bit packet using 18-bit container) | RGB666_PACKET |
| RGB565 (using 16-bit container)               | RGB565        |

#### 7.2.2.4.7 Synchronization Codes

Each frame can be identified by two synchronization codes: One for the start of vertical synchronization pulse (VSSC) and one for the end of the vertical synchronization pulse (VSEC). Each line can be identified by two synchronization codes: One for the start of horizontal synchronization pulse (HSSC) and one for the end of the horizontal synchronization pulse (HSEC). The synchronization events may not be required by the display (peripheral): They are optional. Users can program which sync events are generated to the display from the timings received from the display controller in video mode. When data are received on the L4 interconnect slave port, the synchronization codes are not automatically generated by the protocol engine. They can be provided on the L4 interconnect port by writing to the registers with limited timing control. It is highly recommended to use the video port from the display controller to receive the synchronization events to automatically generate the short synchronization packets to the peripheral. When the DSI protocol engine detects that the VSYNC signal from the display controller transitions from inactive to active state, the VSSC short packet replaces the following HSSC corresponding to the following HSYNC synchronization short packet (if the generation is enabled). When the transition from active to inactive state is detected, the VSEC short packet is generated (if the generation is enabled) replacing the HSSC synchronization packet corresponding to the following HSYNC. When the DSI protocol engine detects that the HSYNC signal from the display controller transition from inactive to active state, the HSSC short packet is generated (if the generation is enabled). When the transition from active to inactive state is detected, the HSEC short packet is generated (if the generation is enabled). For the first frame, any HSYNC and data received on the video port before the first VSYNC should be ignored. Because the first VSYNC sent to the display is also recognized as a HSYNC for the first line, there should be no HSYNC sent for the first line. To send the synchronization codes, the DSI protocol engine uses the short packets. [Table 7-14](#) summarizes the 6-bit DT synchronization code values.

**Table 7-14. Synchronization Codes**

| Synchronization Code     | Value | Comments |
|--------------------------|-------|----------|
| V sync start code (VSSC) | 0x1   | Optional |
| V sync end code (VSEC)   | 0x11  | Optional |
| H sync start code (HSSC) | 0x21  | Optional |
| H sync end code (HSEC)   | 0x31  | Optional |

#### 7.2.2.4.8 Blanking

To keep the DSI link in HS state while using the video mode, during blanking periods, the long blanking packets are sent to the display. The DSS.DSI\_VM\_TIMINGi (i between 1 and 7) registers define the size of the long blanking packets after:

- Horizontal sync start code (short packet)
- Horizontal sync end code (short packet)
- Vertical sync start code (short packet)
- Vertical sync end code (short packet)
- Pixels (long packet)

[Table 7-15](#) defines the short packet values for the synchronization packets:

**Table 7-15. Sync Short Packet Values**

| Virtual Channel ID | Sync Code | Header (1st Byte) | Header (2nd Byte): Data Field LSB | Header (3rd Byte): Data Field MSB | Header (ECC)                  |
|--------------------|-----------|-------------------|-----------------------------------|-----------------------------------|-------------------------------|
| 0x0                | 0x1       | 0x1               | 0x0                               | 0x0                               | See note following this table |
|                    | 0x11      | 0x11              |                                   |                                   |                               |
|                    | 0x21      | 0x21              |                                   |                                   |                               |
|                    | 0x31      | 0x31              |                                   |                                   |                               |
| 0x1                | 0x1       | 0x41              |                                   |                                   |                               |
|                    | 0x11      | 0x51              |                                   |                                   |                               |
|                    | 0x21      | 0x61              |                                   |                                   |                               |
|                    | 0x31      | 0x91              |                                   |                                   |                               |
| 0x2                | 0x1       | 0x81              |                                   |                                   |                               |
|                    | 0x11      | 0x81              |                                   |                                   |                               |
|                    | 0x21      | 0xA1              |                                   |                                   |                               |
|                    | 0x31      | 0xB1              |                                   |                                   |                               |
| 0x3                | 0x1       | 0xC1              |                                   |                                   |                               |
|                    | 0x11      | 0xD1              |                                   |                                   |                               |
|                    | 0x21      | 0xC1              |                                   |                                   |                               |
|                    | 0x31      | 0xF1              |                                   |                                   |                               |

**NOTE:**

- If the ECC is enabled by setting the DSS.DSI\_VCn\_CTRL[8] ECC\_TX\_EN bit to 1 for the VC in video mode, the ECC value is calculated; otherwise, 0x00 is used for the blanking long packets and sync short packets. If the CRC is enabled by setting the DSS.DSI\_VCn\_CTRL[7] CS\_TX\_EN bit to 1 for the VC in video mode, the check-sum value is calculated; otherwise, 0x00 is used for the blanking long packets.
- In other cases, when the DSS.DSI\_VCn\_CTRL[7] CS\_TX\_EN bit is set to 0, the value 0x00 is always used for the CRC (long packets). When the DSS.DSI\_VCn\_CTRL[8] ECC\_TX\_EN bit is set to 0, the value 0x00 is used for the ECC for short and long packets, except when the header is provided by the register, since the ECC field is available in the register. It can be used to generate invalid ECC values when the header is provided by the register.

The link [lane(s) and clock separately] can be put in ULPS mode. While using the blanking values formerly defined, the packets (short and long) are considered in HS mode.

Timing parameters VSA, VBP, VFP, HSA, HBP, HFP, VACT, and  $t_L$  are defined in the DSS.DSI\_VM\_TIMINGx (x between 1 and 7) register. HSA, HBP, HFP, and  $t_L$  are defined using the byte clock unit (TxByteClkHS) and also in low-power clock cycles (TxClkEsc). VSA, VBP, VFP, and VACT are defined in term of number of lines. When the HS blanking packets are sent during the blanking periods, the parameters are used to determine the blanking packet payload size (taking into account the 4-byte header and the 2-byte check sum).

The configuration of the display controller timing generator must be used when the display controller timings are used to generate the DSI HS video mode transfer.

Special care must be taken in the case of the last line of the frame. The LPS transition is required when the link is in HS mode for the whole frame.

When BTA is sent for the data packets, the following blanking period cannot be used for sending any data from the TX FIFO. When the blanking period starts with one HS packet from one VC, it can only be followed by another HS packet from the same VC, or by trigger (BTA for example). When there is no more HS data to send for this VC, the lane is in LPS. When the blanking period starts with one LP packet from one VC, it can only be followed by another LP packet from the same VC, by another VC, by trigger (BTA

for example), or by extra LP NULL packets. If the trigger has been sent, it is not possible to send any more data. When there is no more data from the TX FIFO to send in LP mode or the trigger has been sent, the lane is put into LPS. If the lanes must be kept in HS mode during blanking periods (except for the last blanking period of the frame), the HS blanking packets must be used. In case one trigger is sent at the beginning of the blanking period, the rest of the blanking period is in ULPS.

Figure 7-48 and Figure 7-49 show a nonburst transfer in DSI video mode with, and without VE and HE, respectively.

**Figure 7-48. DSI Video Mode: Nonburst Transfer With VE and HE**

dss-148

**Figure 7-49. DSI Video Mode: Nonburst Transfer Without VE and HE**

dss-149

**NOTE:** HSA timing is not used and does not have to be programmed when HE short packet is not generated.

**Figure 7-50. DSI Video Mode: Burst Transfer Without VE and HE**

dss-150

**NOTE:** HSA timing is not used and does not have to be programmed when HE short packet is not generated.

In [Figure 7-49](#) and [Figure 7-50](#), if HSync end short packet is not generated (HSA does not exist), HBP must be other than 0.

#### 7.2.2.4.9 Frame Structures

[Figure 7-51](#) shows the general DSI frame structure.

**Figure 7-51. DSI General Frame Structure**

**Key:**

Command mode

dss-153

#### 7.2.2.4.10 Virtual Channels

The DSI protocol layer transports VCs. The purpose of VCs is to separate different data flows, which are interleaved in a same data stream. Each VC is identified by a unique channel identification number in the packet header. The channel identification number is encoded in 2-bits. The DSI protocol engine determines the channel identifier number to be used for generating the packet header and multiplexes the interleaved data streams. The DSI protocol engine supports multiple concurrent VCs: Up to 4. [Table 7-16](#) summarizes the VC values used for each channel.

**Table 7-16. Virtual Channel Values**

| Virtual Channel Number | Value |
|------------------------|-------|
| Virtual channel 0      | 0x0   |
| Virtual channel 1      | 0x1   |
| Virtual channel 2      | 0x2   |
| Virtual channel 3      | 0x3   |

In the case of multiple displays connected to the single DSI port on the host, a hub may be used to root the data stream to the appropriate display based on the VC ID. Typically, VC ID 0x0 is used for the primary display and 0x1 for the secondary. The hub may have its own VC ID to provide communication capability between the host and the hub.

#### 7.2.2.5 Pixel Data Formats

This section summarizes how the DSI supported pixel data formats in video mode are transmitted over the serial interface. For pixel formats in command mode. The DSI protocol engine can cope with all data formats given that the data line length sent through the DSI physical protocol is a multiple of a pixel. This condition is required for the DSI protocol engine to work properly.

##### 7.2.2.5.1 24 Bits per Pixel - RGB Color Format, Long Packet

[Figure 7-54](#) shows the RGB888 format.

**Figure 7-54. 24 Bits per Pixel RGB Color Format, Long Packet**

dss-154

Packed pixel stream 24-bit format is a long packet used to transmit image data formatted as 24-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. The pixel format is red (8 bits), green (8 bits), and blue (8 bits), in that order. Each color component occupies one byte in the pixel stream; no components are split across byte boundaries. Within a color component, the LSB is sent first, the MSB last.

#### 7.2.2.5.2 18 Bits per Pixel (Loosely Packed) - RGB Color Format, Long Packet

Figure 7-55 details the RGB666 format.

**Figure 7-55. 18 Bits per Pixel (Loosely Packed) RGB Color Format, Long Packet**

dss-155

In the 18-bit pixel loosely-packed format, each R, G, or B color component is six bits but is shifted to the upper bits of the byte, such that the valid pixel bits occupy bits [7:2] of each byte. Bits [1:0] of each payload byte representing active pixels are ignored. As a result, each pixel requires three bytes as it is transmitted across the link. This requires more bandwidth than the packed format, but requires less shifting and multiplexing logic in the packing and unpacking functions on each end of the link. This format is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. The pixel format is red (6 bits), green (6 bits), and blue (6 bits) in that order. Within a color component, the LSB is sent first, the MSB last.

#### 7.2.2.5.3 18 Bits per Pixel (Packed) - RGB Color Format, Long Packet

Figure 7-56 details the RGB666\_PACKED format.

**Figure 7-56. 18 Bits per Pixel (Packed) RGB Color Format, Long Packet**

dss-156

Packed pixel stream 18-bit format (packed) is a long packet. It is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. Pixel format is red (6 bits), green (6 bits), and blue (6 bits), in that order. Within a color component, the LSB is sent first, the MSB last. With this format, it is strongly recommended that the total line width be a multiple of four pixels (nine bytes).

#### 7.2.2.5.4 16 Bits per Pixel - RGB Color Format, Long Packet

Figure 7-57 details the RGB565 format.

**Figure 7-57. 16 Bits per Pixel RGB Color Format, Long Packet**

Packed pixel stream 16-bit format is a long packet used to transmit image data formatted as 16-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. Pixel format is five bits red, six bits green, five bits blue, in that order. Note that the *green* component is split across two bytes. Within a color component, the LSB is sent first, the MSB last.

### 7.2.3 TV Display Support

The TV display path includes the following modules:

- Display controller
- Video encoder
- Video DAC stage comprising two single 10-bit DACs (AVDAC1 and AVDAC2) with video amplifiers

The display controller module receives synchronization signals from the video encoder and synchronously sends pixel data to the video encoder with these signals. The digital output of the display controller is always a 24-bit RGB value based on a pixel request from the video encoder.

The video encoder converts RGB video signals to conform to the NTSC/PAL standard analog video. The video encoder includes an integrated synchronization signal generator and two single channel video digital-to-analog converters (DACs) with video amplifiers, data manager, luma stage, chroma stage, modulator, and a control interface.

The video encoder also provides the synchronization signals to the display controller: VSYNC, active VIDeo (AVID), and field ID (FID).

**Figure 7-58** is a block diagram of the TV display interface (S-video mode, DC coupled, High Full Scale Swing).

**Figure 7-58. TV Display Interface (S-video mode, DC coupled, High FS Swing)**

camdss\_GN3-001

Figure 7-59 is a block diagram of the TV display interface (Composite mode, DC coupled, High Full Scale Swing).

**Figure 7-59. TV Display Interface (Composite Mode, DC coupled, High FS Swing)**

dss-191

Figure 7-60 is a block diagram of the TV display interface (Composite mode, AC coupled, Low Full Scale Swing).

**Figure 7-60. TV Display Interface (Composite Mode, AC coupled, Low FS Swing)**

dss-401

**NOTE:** In composite video mode, the video DAC2 chroma output must be disabled by setting the DSS.VENC\_OUTPUT\_CONTROL[2] CHROMA\_ENABLE bit to 0.

Figure 7-61 is a block diagram of the TV display interface (Bypass mode, Dual Channel).

**Figure 7-61. TV Display Interface (Bypass Mode, Dual Channel)**

dss-402

Table 7-17 describes the interface signals to/from the TV set for TV display support.

**Table 7-17. TV Display Interface Pins**

| Pin Name     | Type <sup>(1)</sup> | Description                                                                                                                                                                                                        |
|--------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cvideo1_out  | O                   | Analog luma or composite video output. An external resistor Rout1 is connected between this node and the cvideo1_vfb pin. Note that this is the output node that drives the load (75 Ω).                           |
| cvideo2_out  | O                   | Analog chroma video output. An external resistor Rout2 is connected between this node and the cvideo2_vfb pin. This is the output node that drives the load (75 Ω).                                                |
| cvideo1_vfb  | O                   | Amplifier feedback node. An external resistor Rout1 is connected between this node and cvideo1_out.                                                                                                                |
| cvideo2_vfb  | O                   | Amplifier feedback node. An external resistor Rout2 is connected between this node and cvideo2_out.                                                                                                                |
| cvideo1_rset | I/O                 | External resistor pin to set the reference current of the AVDAC1. The value of the resistor (Rset) depends on the mode of operation. Refer to <a href="#">Table 7-18, Typical values for Rout, Rset and Cout</a> . |
| vdda_dac     | Power               | Analog supply voltage for the video DAC stage                                                                                                                                                                      |
| vssa_dac     | Power               | Analog ground for the video DAC stage                                                                                                                                                                              |

<sup>(1)</sup> O = Output, Power = Power pin

[Table 7-18](#) lists the typical values for the Rout1/2 and Rset resistors and the Cout capacitor, for different modes of the TV display interface.

**Table 7-18. Typical values for Rout, Rset and Cout**

|        | S-video, DC coupled, High FS Swing | Composite, DC coupled, High FS Swing | Composite, AC coupled, Low FS Swing | Bypass, Dual channel | Unit |
|--------|------------------------------------|--------------------------------------|-------------------------------------|----------------------|------|
| Rout 1 | 2700                               | 2700                                 | 2700                                | 1500                 | Ohm  |
| Rout 2 | 2700                               | N/A                                  | N/A                                 | 1500                 | Ohm  |
| Rset   | 4700                               | 4700                                 | 6800                                | 10000                | Ohm  |
| Cout   | N/A                                | N/A                                  | 220                                 | N/A                  | μF   |

**CAUTION**

- High full-scale swing is the default mode. Low-swing mode does not comply with the NTSC and PAL video standards. It must be used only for backward compatibility to the OMAP35x.
- All resistor values in [Table 7-18](#) must be within  $\pm 1\%$  tolerance range.
- cvideo1\_out and cvideo2\_out are very high-frequency analog signals and must be routed with extreme care. As a result, the path of these signals must be as short as possible, and as isolated as possible from other interfering signals.
- During board design, the onboard traces and parasites must be matched for the two channels. cvideo1\_vfb and cvideo2\_vfb pins are the most sensitive pins in the TV out system. The onboard parasitic capacitance associated with these two pins must be less than 0.5 pF. Low onboard resistance is required for the traces that connect the Rout1/Rout2 to the cvideo1\_vfb/cvideo2\_vfb and TV OUT pins (cvideo1\_out and cvideo2\_out). The resistance on those trace affects output impedance matching. Therefore, Rout1 and Rout2 resistors are suggested to be placed as close as possible to the device pins. The onboard traces lead to the TV OUT pins must have a characteristic impedance of  $75 \Omega$  starting from the closest possible place to the device pin output.
- If the TV output is not used, the following configurations for the AVDACs pins must be applied:
  - Configuration 1
    - cvideo1\_out must be grounded.
    - cvideo1\_vfb must be grounded.
    - cvideo2\_out must be grounded.
    - cvideo2\_vfb must be grounded.
    - cvideo1\_rset must be grounded.
    - vdda\_dac must be grounded.
    - vssa\_dac must be grounded.
  - Configuration 2
    - cvideo1\_out must be floating, left unconnected.
    - cvideo1\_vfb must be floating, left unconnected.
    - cvideo2\_out must be floating, left unconnected.
    - cvideo2\_vfb must be floating, left unconnected.
    - cvideo1\_rset must be floating, left unconnected.
    - vdda\_dac must be grounded.
    - vssa\_dac must be grounded.
- To avoid current leakage, the following bits must be set to 0:
  - DSS.[DSS\\_CONTROL\[5\]](#) DAC\_POWERDN\_BGZ
  - DSS.[VENC\\_OUTPUT\\_CONTROL\[2:0\]](#)
  - PRCM.CM\_FCLKEN\_DSS[2] EN\_TV
  - CONTROL.CONTROL\_DEVCONF[18] TVOUTBYPASS

**7.2.3.1 TV Output and Data Format**

The output data to the TV set are the analog composite data from the video DAC stage. The following video standards are supported:

- NTSC-J, M

- PAL-B, D, G, H, I
- PAL-M

### 7.2.3.2 Digital-to-Analog Converters

The video DAC stage includes the following main features:

- 1.1-V digital power supply, 1.8-V analog power supply
- 10-bit resolution
- DNL within 1 LSB and INL within 1 LSB (in bypass mode)
- Sample rate of up to 60 mega samples per second (MSPS)
- Support composite/S-video DC or AC coupled output
- Support TVOUT buffer bypass mode (DAC-only mode)
- Full-scale voltage output: minimum 1.2 Vpp with a 75- $\Omega$  load
- Internal TV detect feature
- Signal-to-noise ratio (SNR) is 54 dB (taking into account the ac coupling)
- Suitable for low-power consumer video applications
- Power-down mode with less than 12- $\mu$ A standby current
- Differential gain error and differential phase error: within 3 percent and 1 degree, respectively

---

**NOTE:** To enhance the TV color display, it is highly recommended to set the DSS.DSS\_CONTROL[4] DAC\_DEMEN bit.

For more information about the video DAC stage architecture and configuration, see [Section 7.4.7.7, Video DAC Stage – Architecture and Control](#).

---

## 7.3 Display Subsystem Integration

This section describes the integration of the display subsystem and details clocks, resets, hardware requests, and power modes.

[Figure 7-62](#) shows the integration of the display subsystem in the device.

Figure 7-62. Display Subsystem Integration

camdss-036

### 7.3.1 Clocking, Reset, and Power-Management Scheme

#### 7.3.1.1 Clocks

The power, reset, and clock management (PRCM) module provides six clock signals to the display subsystem: The L3 interface clock (DSS\_L3\_ICLK) and the L4 interface clock (DSS\_L4\_ICLK), with frequencies equal to the L3 interconnect clock and the L4 interconnect clock, respectively; two configurable functional clocks (DSS1\_ALWON\_FCLK and DSS2\_ALWON\_FCLK); and one other functional clock (DSS\_TV\_FCLK).

The DSI PLL provides two functional clock signals to the display subsystem: DSI1\_PLL\_FCLK and DSI2\_PLL\_FCLK.

[Figure 7-63](#) details the clock tree for the display subsystem.

**Figure 7-63. Display Subsystem Clock Tree**

camdss-158

**NOTE:** A synchronization signal is sent by the display controller (DISPC) to the DSI protocol engine. This signal, named DISPC\_UPDATE\_SYNC, is used to inform the DSI protocol engine that it must be unsynchronized with the display controller.

Table 7-19 describes the different clocks with their possible frequency values.

**Table 7-19. Display Subsystem Clocks**

| Clock Signal    | Attribute          | Module                     | Frequency                                                                           | Comment                                                                                                                                  |
|-----------------|--------------------|----------------------------|-------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| DSS_L3_ICLK     | L3 interface clock | DSS                        | (See <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )                | L3 interface clock from PRCM                                                                                                             |
| DSS_L4_ICLK     | L4 interface clock | DSS                        | (See <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )                | L4 interface clock from PRCM                                                                                                             |
| DSS1_ALWON_FCLK | Functional clock   | DISPC, DSI protocol engine | Up to 173 MHz at nominal voltage (OPP100), and up to 100 MHz at low voltage (OPP50) | From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK)                                                                                              |
| DSS2_ALWON_FCLK | Functional clock   | DSI PLL                    | 12/13/16.8/19.2/26/38.4 MHz                                                         | From PRCM: SYS_CLK                                                                                                                       |
| DSI1_PLL_FCLK   | Functional clock   | DISPC                      | Up to 173 MHz at nominal voltage (OPP100), and up to 100 MHz at low voltage (OPP50) | From DSI PLL and HS divider                                                                                                              |
| DSI2_PLL_FCLK   | Functional clock   | DSI protocol engine        | Up to 173 MHz at nominal voltage (OPP100), and up to 100 MHz at low voltage (OPP50) | From DSI PLL and HS divider                                                                                                              |
| DSS_TV_FCLK     | Functional clock   | DSS, video mode DAC        | 54 MHz or sys_alt_clk (up to 59 MHz)                                                | From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK) or External input clock (See <a href="#">Chapter 3, Power, Reset, and Clock Management</a> ) |

To enable or disable each functional clock, set the following bit (1: Enable, 0: Disable):

- PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 bit to enable DSS1\_ALWON\_FCLK
- PRCM.CM\_FCLKEN\_DSS[1] EN\_DSS2 bit to enable DSS2\_ALWON\_FCLK
- PRCM.CM\_FCLKEN\_DSS[2] EN\_TV bit to enable DSS\_TV\_FCLK

To enable or disable the DSS\_L3\_ICLK and DSS\_L4\_ICLK interface clocks, write (1: Enable, 0: Disable) to the PRCM.CM\_ICLKEN\_DSS[0] EN\_DSS bit.

**NOTE:** Note that it is not possible to gate/stop L3 clock and keep L4 clock running.

- L3 and L4 interface clock

The DSS\_L3\_ICLK clock is only used by the display controller interface to fetch the pixel data. The DSS\_L4\_ICLK is used to access the L4 interconnect for configuring all the display subsystem registers.

**NOTE:** A clock generated internally from the L3 interface clock allows the submodules to be configured and is the functional clock for the RFBI. All the display subsystem registers are configured through the display subsystem register.

- Display controller functional clocks

The display controller can use either the DSS1\_ALWON\_FCLK or the DSI1\_PLL\_FCLK functional

clock.

To select the DSS1\_ALWON\_FCLK functional clock (the default clock selected after reset), write 0 in the DSS.[DSS\\_CONTROL\[0\]](#) DISPC\_CLK\_SWITCH bit; to select the DS1\_PLL\_FCLK functional clock, write 1 in the DSS.[DSS\\_CONTROL\[0\]](#) DISPC\_CLK\_SWITCH bit.

---

**NOTE:** The DSS1\_ALWON\_FCLK and DS1\_PLL\_FCLK functional clocks must be active (the PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 and DS1 PLL programmed correctly) to switch from one functional clock to another. The new functional clock is effective when the next vertical blanking interval occurs. This is true only if the DSS.[DISPC\\_CONTROL\[5\]](#) GOLCD bit is set to 1.

---

Depending on the DLL4 input clock frequency, the DSS1\_ALWON\_FCLK can be adjusted by setting the PRCM.CM\_CLKSEL\_DSS[4:0] CLKSEL\_DSS1 bit field.

- DS1 PLL functional clock (DSI\_PLL\_REFCLK)

The DS1 PLL controller module can use either the DSS2\_ALWON\_FCLK (from PRCM) or the PCLKFREE (from DISPC) functional clock. To select the DSS2\_ALWON\_FCLK functional clock (default clock selected after reset), write 0 in the DSS.[DSI\\_PLL\\_CONFIGURATION2\[11\]](#) DS1\_PLL\_CLKSEL bit; to select the PCLKFREE functional clock, write 1 in the DSS.[DSI\\_PLL\\_CONFIGURATION2\[11\]](#) DS1\_PLL\_CLKSEL bit.

- DS1 protocol engine functional clocks (DSI\_FCLK)

The DS1 protocol engine can use either the DSS1\_ALWON\_FCLK (from PRCM) or the DS12\_PLL\_FCLK (from DS1 PLL) functional clock. To select the DSS1\_ALWON\_FCLK functional clock (default clock selected after reset), write 0 in the DSS.[DSS\\_CONTROL\[1\]](#) DS1\_CLK\_SWITCH bit; to select the DS12\_PLL\_FCLK functional clock, write 1 in the DSS.[DSS\\_CONTROL\[1\]](#) DS1\_CLK\_SWITCH bit.

---

**NOTE:** It is possible to switch between these two clocks, even when both of them are not active.

---

- There are five clock domains in the DS1 module:

- Byte clock domain:

TxByteClkHS is generated from the bit clock and converted into a byte clock. The maximum frequency is 112.5 MHz at nominal voltage (OPP100), and 100 MHz at low voltage (OPP50). It is generated by the DS1 complex I/O.

- Functional clock domain

The DS1\_FCLK is the functional clock for the DS1 protocol engine module. The maximum frequency is 173 MHz (nominal voltage) and 100 MHz (low voltage). It must always be equal to or higher than the byte (TxByteClkHS), L4 interconnect (DSS\_L4\_ICLK), and video port (VP\_CLK) clocks. The software must configure the clocks correctly.

- L4 interface clock domain

The DSS\_L4\_ICLK is used in the L4 interconnect port domain. The maximum frequency is 100 MHz at nominal voltage.

- The video port domain

The pixel clock (PCLK) on the video port is used by the video port domain to capture the pixels from the display controller. The maximum frequency of VP\_CLK used as the functional clock for the video port domain is 173 MHz at nominal voltage and 96 MHz at low voltage.

- Serial Configuration Port (SCP) and Power Control (PWR) interfaces

The DSS\_L4\_ICLK is the functional clock.

**NOTE:**

- There is no clock domain for RxClkEsc because it is used as an enable and not as a clock by the DSI protocol engine module
- The clock domains are asynchronous (except for L4 interconnect port and SCP/PWR because both of them use DSS\_L4\_ICLK). The clocks used for the L4 interconnect port and SCP/PWR interface must be balanced.
- If video mode is used, the display controller functional clock must be generated using a clock from the DSI PLL.

- 
- Video encoder functional clock

The DSS\_TV\_FCLK is divided into three balanced clocks, depending on the clock mode selected (see [Table 7-20](#)).

**Table 7-20. Possible Digital Clock Division for the Video Encoder**

| Clock Output           | Clock Mode    |                          |
|------------------------|---------------|--------------------------|
|                        | Clock Mode 0  | Clock Mode 1             |
| Video encoder clock 4x | DSS_TV_FCLK   | DSS_TV_FCLK or 0 (gated) |
| Video encoder clock 2x | DSS_TV_FCLK/2 | DSS_TV_FCLK              |
| Video encoder clock 1x | DSS_TV_FCLK/4 | DSS_TV_FCLK/2            |

The clock mode is defined by the [DSS\\_CONTROL\[2\]](#) VENC\_CLOCK\_MODE register bit:

- In the case of clock mode 1, the [DSS\\_CONTROL\[3\]](#) VENC\_CLOCK\_4X\_ENABLE bit is used to control clock gating.
- In the case of clock mode 0, the VENC\_CLOCK\_4X\_ENABLE bit must be set to 0x1 by software.

---

**NOTE:** After reset, clock mode 0 is selected by default, and the DSS\_TV\_CLK clock is disabled. The DSS\_TV\_CLK / 4 in mode 0, or the DSS\_TV\_CLK / 2 in mode 1, is used in the DISPC module to send data to the video encoder.

---

**NOTE:** Clock mode 1 can be used for power-saving purposes, or if a 27-MHz external clock is provided to the video encoder.

---

DSS\_TV\_FCLK can be adjusted depending on the DPLL4 input clock frequency by setting the PRCM.CM\_CLKSEL\_DSS[12:8] CLKSEL\_TV bit field. If the DPLL4 is selected, the DSS\_TV\_FCLK is provided by the DPLL4\_ALWON\_FCLKOUTM3X2 clock.

---

**NOTE:** If the DSS\_TV\_FCLK is not provided by DPLL4 but rather by the sys\_alt\_clk pin, an external clock generator must be connected to this pin. In this case, a 54-MHz clock is needed for PAL or NTSC 601, a 49.09-MHz clock is needed for NTSC square pixel, and a 59-MHz clock is needed for PAL square pixel.

---

- Video DAC stage clocks

The video DAC stage uses one distinct clock: The DSS\_TV\_FCLK. The video data are latched on the positive edge of the DSS\_TV\_FCLK clock.

### 7.3.1.2 Resets

#### 7.3.1.2.1 Hardware Reset

The display subsystem receives its reset signal DSS\_RST (the reset signal of the display subsystem [DSS] power domain) from the PRCM module.

### 7.3.1.2.2 Software Reset

The display subsystem can receive a software reset propagated through all of the submodules and used to initialize the display subsystem. To apply the reset, write to the DSS.[DSS\\_SYSCONFIG\[1\]](#) SOFTRESET bit (1: Reset; 0: Normal). The DSS.[DSS\\_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is 1.

**NOTE:** The display controller, the DSI protocol engine, and the RFBI modules also have their own software reset functionality. To access this reset, access the DSS.[DISPC\\_SYSCONFIG\[1\]](#) SOFTRESET bit for the display controller, the DSS.[DSI\\_SYSCONFIG\[1\]](#) SOFTRESET bit for the DSI protocol engine, and the DSS.[RFBI\\_SYSCONFIG\[1\]](#) SOFTRESET bit for the RFBI module.

To properly reset these modules, 0x2 is the only valid value to write to these registers.

#### CAUTION

All the interface and functional clocks, even for the TV output, must be provided to the display subsystem to update the RESETDONE status bit correctly.

### 7.3.1.3 Power Domain

The display subsystem modules are on the display subsystem (DSS) power domain and on the VDD2 voltage domain, except for the video DAC stage, which are on the analog vdda\_dac voltage domain.

### 7.3.1.4 Power Management

#### 7.3.1.4.1 Clock Activity Mode

The display controller clocks can be configured in one of the following clock activity modes:

- DSS.[DISPC\\_SYSCONFIG\[9:8\]](#) CLOCKACTIVITY bit field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.[DISPC\\_SYSCONFIG\[9:8\]](#) CLOCKACTIVITY bit field set to 0x1: The functional clocks can be can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.[DISPC\\_SYSCONFIG\[9:8\]](#) CLOCKACTIVITY bit field set to 0x2: The interface clocks can be can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.[DISPC\\_SYSCONFIG\[9:8\]](#) CLOCKACTIVITY bit field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSI protocol engine clocks can be configured in one of the following clock activity modes:

- DSS.[DSI\\_SYSCONFIG\[9:8\]](#) CLOCKACTIVITY bit field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.[DSI\\_SYSCONFIG\[9:8\]](#) CLOCKACTIVITY bit field set to 0x1: The functional clocks can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.[DSI\\_SYSCONFIG\[9:8\]](#) CLOCKACTIVITY bit field set to 0x2: The interface clocks can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.[DISPC\\_SYSCONFIG\[9:8\]](#) CLOCKACTIVITY bit field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSS power domain clock activity status is logged in the PRCM.CM\_CLKSTST\_DSS[0] CLKACTIVITY\_DSS status bit. When set to 0, there is no domain clock activity. When set to 1, the DSS power domain clock is active.

- NOTE:** The display subsystem interface clock can be dependent on the DSS power domain state. This is configured with PRCM.CM\_AUTOIDLE\_DSS[0] AUTO\_DSS bit:
- When the AUTO\_DSS bit is set to 0 (reset value): The display subsystem interface clock is not related to the DSS power domain state transition.
  - When the AUTO\_DSS bit is set to 1: The display subsystem interface clock is automatically enabled or disabled along with the DSS power domain state transition.

#### 7.3.1.4.2 Autoidle Mode

The RFBI, display controller, DSI protocol engine, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.[DSS\\_SYSCONFIG](#)[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.[RFBI\\_SYSCONFIG](#)[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.[DISPC\\_SYSCONFIG](#)[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.[DSI\\_SYSCONFIG](#)[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the DSI protocol engine
- DSS.[DISPC\\_CONFIG](#)[9] FUNCATED bit (1: Functional clocks gated enabled; 0: Functional clocks gated disabled) for the display controller

- NOTE:** All the bits listed above (except for the FUNCATED bit) are set to 1 by default. It is highly recommended to set all the bits to 1 to save power.

#### 7.3.1.4.3 Idle Mode

The display controller, DSI protocol engine, and RFBI can be configured into one of the following acknowledgment modes:

- Force-idle mode: The module immediately enters the idle state on receiving a low-power mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state. Set the DSS.[DISPC\\_SYSCONFIG](#)[4:3] SIDLEMODE bit field to 0x0 (reset value) for display controller, set the DSS.[DSI\\_SYSCONFIG](#)[4:3] SIDLEMODE bit field to 0x0 (reset value) for DSI protocol engine, and, finally, the DSS.[RFBI\\_SYSCONFIG](#)[4:3] SIDLEMODE bit field to 0x0 (reset value) for RFBI.
- No-idle mode: The module never enters the idle state. Set the DSS.[DISPC\\_SYSCONFIG](#)[4:3] SIDLEMODE bit field to 0x1 for display controller, set the DSS.[DSI\\_SYSCONFIG](#)[4:3] SIDLEMODE bit field to 0x1 for DSI protocol engine, and, finally, the DSS.[RFBI\\_SYSCONFIG](#)[4:3] SIDLEMODE bit field to 0x1 for RFBI.
- Smart-idle mode:
  - Display controller: After receiving a low-power-mode request from the PRCM module, the display controller module enters the idle state when all the following conditions are satisfied:
    - All asserted output interrupts are acknowledged (no interrupt pending).
    - The display controller does not use anymore the L4 interface clock (DSS\_L4\_ICLK).
  - DSI protocol engine: After receiving a low-power-mode request from the PRCM module, the DSI protocol engine enters the idle state when all the following conditions are satisfied:
    - All asserted output interrupts are acknowledged (no interrupt pending).
    - The DSI protocol engine does not use the L4 interface clock (DSS\_L4\_ICLK) anymore.
    - The SCP and PWR transactions are complete.
    - No data remains in the TX FIFO (data waiting in the FIFO to be sent to the peripheral).

To configure the display subsystem in smart-idle mode, set the DSS.[DISPC\\_SYSCONFIG](#)[4:3] SIDLEMODE bit field to 0x2 for display controller, set the DSS.[DSI\\_SYSCONFIG](#)[4:3] SIDLEMODE bit field to 0x2 for DSI protocol engine, and, finally, the DSS.[RFBI\\_SYSCONFIG](#)[4:3] SIDLEMODE bit field to 0x2 for RFBI.

Once the idle handshake protocol is over:

- The DSS L4 interface clock (DSS\_L4\_ICLK) can be shutdown at any time.
- Any transaction on the L4 configuration port is ignored.

#### 7.3.1.4.4 Wake-Up Mode

The Display Controller (DISPC) supports the wake-up protocol. The mode is selected by programming the appropriate value in the DSS.[DISPC\\_SYSConfig\[2\]](#) ENWAKEUP bit. The wake-up signal is asserted when the DISPC is in idle mode and when anyone of the following events occur:

- Graphics pipe is enabled and data fetch is not completed for graphics window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video1 pipe is enabled and data fetch is not completed for video1 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video2 pipe is enabled and data fetch is not completed for video2 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- The current pixel is the last pixel displayed on the LCD panel if it is not the last frame.
- The current pixel is the last pixel displayed on the digital panel if it is not the last frame.

If software users set the DSS.[DISPC\\_CONFIG\[17\]](#) FIFOFILLING bit, when one of the active pipe reaches the low threshold and should refill the FIFO for the current frame, the other pipes also refill their own FIFOs, even if the low threshold has not been reached. This is used to improve the probability of increasing the time when there is no access to the L3 interconnect (MStandby asserted, affects power savings).

Once the wake-up signal is asserted, the WAKEUP interrupt request is generated. The wake-up signal is deasserted when the idle request is no longer activated.

#### 7.3.1.4.5 Standby Mode

As part of the system-wide power-management scheme, the display controller can enter standby mode.

To configure the display controller, write the DSS.[DISPC\\_SYSConfig\[13:12\]](#) MIDLEMODE bit field (00: Forced standby; 01: No standby; 10: Smart standby) in one of the following standby modes:

- Forced standby mode (default mode): The module enters standby mode when the module is disabled.
- No standby mode: The module never enters standby mode.
- Smart standby mode: The module enters standby state when the DISPC module is disabled or when all the three following events occur:
  - Graphics pipe is disabled or graphics pipe is enabled but data fetch completed for graphics window, or graphics pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
  - Video1 pipe is disabled or video1 pipe is enabled but data fetch completed for video1 window, or video1 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
  - Video2 pipe is disabled or video2 pipe is enabled but data fetch completed for video2 window, or video2 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.

When in standby mode, the display controller does not generate transactions on the L3 master port. Standby is active when the PRCM module confirms this mode.

The display subsystem standby mode activity can be monitored with the PRCM.CM\_IDLEST\_DSS[0] ST\_DSS status register. When this register is read to 0, the display subsystem is accessible and the interface clock running; when it is read to 1, the display subsystem is in standby mode.

##### 7.3.1.4.5.1 Conditions to Exit Standby Mode

The following conditions allow the subsystem to exit standby mode:

- Forced standby mode: Standby mode is exited when the display controller is enabled.
- Smart standby mode: Standby mode is exited when any one of the following events occurs:

- Graphics pipe is enabled and data fetch is not completed for graphics window, and number of data bytes in FIFO is less than the low threshold programmed value.
- Video1 pipe is enabled and data fetch is not completed for video1 window, and number of data bytes in FIFO is less than the low threshold programmed value.
- Video2 pipe is enabled and data fetch is not completed for video2 window, and number of data bytes in FIFO is less than the low threshold programmed value.

#### 7.3.1.4.5.2 Standby Transition Dependency

The sleep transition of the DSS power domain can be dependent or not with respect to MPU domain. This is configured by PRCM.CM\_SLEEPDEP\_DSS[1] EN\_MPU bit:

- When the EN\_MPU bit is set to 0 (reset value): The DSS power domain sleep dependency with the MPU power domain is disabled. The DSS power domain will not enter idle unless the MPU power has previously entered idle.
- When the EN\_MPU bit is set to 1: The DSS power domain sleep dependency with the MPU power domain is enabled. The DSS power domain will enter idle regardless of the power domain state of the MPU.

The sleep transition of the DSS power domain may, or may not depend on the IVA2.2 domain, depending on the configuration of the PRCM.CM\_SLEEPDEP\_DSS[2] EN\_IVA2 bit:

- When the EN\_IVA2 bit is set to 0 (reset value): The DSS power domain sleep dependency on the IVA2.2 power domain is disabled.
- When the EN\_IVA2 bit is set to 1: The DSS power domain sleep dependency on the IVA2.2 power domain is enabled.

#### 7.3.1.4.5.3 Standby Procedure Description

When the display subsystem initiates a standby procedure, it also initiates an standby/wait handshake protocol with the PRCM module that lets the PRCM cut the display subsystem clocks. Depending on the PRCM setting, two modes are available:

- Manual mode
  - DSS1\_ALWON\_FCLK is shut down when the PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 bit is set to 0 and the display subsystem is in standby mode.
  - DSS2\_ALWON\_FCLK is shut down when the PRCM.CM\_FCLKEN\_DSS[1] EN\_DSS2 bit is set to 0 and the display subsystem is in standby mode.
  - DSS\_L3\_ICLK and DSS\_L4\_ICLK are controlled together. They are shut down when the PRCM.CM\_ICLKEN\_DSS[0] EN\_DSS bit is set to 0 and the display subsystem is in standby mode.

##### CAUTION

Do not stop DSS1\_ALWON\_FCLK, or DSS2\_ALWON\_FCLK clock (if used) if the display subsystem is not disabled.

##### CAUTION

DSS\_TV\_FCLK does not depend on the display subsystem standby state. Ensure correct clock management for DSS\_TV\_FCLK.

The clocks are reactivated when the related bits are set to 1 and the display subsystem exits from standby. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

- Hardware- or software-supervised mode

The DSS-power state-transition between active and inactive states can be either hardware or software supervised. This is programmed with the PRCM.CM\_CLKSTCTRL\_DSS[1:0] CLKTRCTRL\_DSS bit field:

- When the CLKTRCTRL\_DSS bit field is set to 0x0 (reset value), the automatic transition is disabled.
- When the CLKTRCTRL\_DSS bit field is set to 0x1, the software-supervised sleep transition is started on the DSS power domain.
- When the CLKTRCTRL\_DSS bit field is set to 0x2, the software-supervised wake-up transition is started on the DSS power domain.
- When the CLKTRCTRL\_DSS bit field is set to 0x3, the automatic transition is enabled. Any transition on the DSS power domain is supervised by the hardware.

#### 7.3.1.4.5.4 Display Subsystem Standby Mode, Power-Saving Use Cases

- Setup
  - Set the display subsystem in smart standby mode.
  - Manually enable DSS\_L3\_ICLK and DSS\_L4\_ICLK.
  - Manually enable DSS1\_ALWON\_FCLK or DSS2\_ALWON\_FCLK.
  - Manually enable DSS\_TV\_FCLK if the video encoder is used.
  - Set the PRCM.CM\_CLKSTCTRL\_DSS[1:0] CLKTRCTRL\_DSS bit field to 0x3 (autocontrol mode supervised by hardware).
- Shut down the display subsystem.
  - Disable the display subsystem.
  - Manually disable DSS1\_ALWON\_FCLK, DSS2\_ALWON\_FCLK, DSS\_TV\_FCLK, DSS\_L3\_ICLK, and DSS\_L4\_ICLK.

For more details on low-power programming settings, see [Section 7.6.2](#).

## 7.3.2 Hardware Requests

### 7.3.2.1 DMA Requests

The display controller, the DSI protocol engine, and the RFBI generate some DMA requests to the sDMA. Figure 7-64 details the DMA tree.

**Figure 7-64. Display Subsystem DMA Tree**

**Table 7-21. DSS DMA Requests Description**

| DMA Request Name | DSS Module          | Mapping  | Description                           |
|------------------|---------------------|----------|---------------------------------------|
| DSS_LINE_TRIGGER | DISPC               | S_DMA_5  | See <a href="#">Section 7.3.2.1.1</a> |
| DSI_DMA_REQ0     | DSI protocol engine | S_DMA_71 | See <a href="#">Section 7.3.2.1.2</a> |
| DSI_DMA_REQ1     | DSI protocol engine | S_DMA_72 | See <a href="#">Section 7.3.2.1.2</a> |
| DSI_DMA_REQ2     | DSI protocol engine | S_DMA_73 | See <a href="#">Section 7.3.2.1.2</a> |
| DSI_DMA_REQ3     | DSI protocol engine | S_DMA_74 | See <a href="#">Section 7.3.2.1.2</a> |
| RFBI_DMA_REQ     | RFBI                | S_DMA_74 | See <a href="#">Section 7.3.2.1.3</a> |

**NOTE:** The DMA requests from the RFBI module (RFBI\_DMA\_REQ) and the DSI protocol engine (DSI\_DMA\_REQ3) are merged on line DSS\_DMA3. The software must only use DSS\_DMA3 on one module at a time (RFBI or DSI protocol engine).

### 7.3.2.1.1 Display Controller DMA Request (Line Trigger)

One DMA synchronization line (DSS\_LINE\_TRIGGER) is connected to the sDMA by the sDMA controller (S\_DMA\_5) input line. This DMA request is not a classical one but a synchronization signal from the display subsystem to the sDMA informing the sDMA that a programmable number of lines are output to the LCD, and that the system memory can be updated. This request is related to an interrupt event described in [Section 7.3.2.2, Interrupt Requests](#). This allows the sDMA channel to be synchronized with the display subsystem internal DMA controller. In other words, it allows to synchronize a memory to memory frame buffer update based on the scan line of the frame buffer in system memory (SDRAM or SRAM) by the display controller. The DSS\_LINE\_TRIGGER DMA request is generated at a programmable line number defined in DSS.DISPC\_LINE\_NUMBER[10:0] LINENUMBER bit field.

### 7.3.2.1.2 DSI Protocol Engine DMA Request

The DSI DMA requests are used to allow automatic transfer by the sDMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported.

### 7.3.2.1.3 RFBI DMA Request

The RFBI\_DMA\_REQ is used to receive data into the RFBI FIFO. The DMA request is always generated when there is enough room in the FIFO to accept the full burst.

### 7.3.2.2 Interrupt Requests

The DSI protocol engine, the DSI complex I/O (DSI\_IRQ), and the display controller (DISPC IRQ) generate one interrupt request each. The DSI\_IRQ and DISPC IRQ lines are merged together in a single interrupt line.

One interrupt line (DSS\_IRQ) is connected to two interrupt controllers:

- MPU interrupt controller (M\_IRQ\_25 input line)
- IVA interrupt handler (IVA2\_IRQ[13] input line)

[Figure 7-65](#) shows the interrupt tree for the DSI protocol engine and DSI complex I/O in detail.

**Figure 7-65. DSI Interrupt Tree**

dss-160

Figure 7-66 details the interrupt tree for the DISPC and the display subsystem.

**Figure 7-66. DISPC and DSS Interrupts Tree**

dss-161

### 7.3.2.2.1 DISPC Interrupt Request

The interrupt line indicates when one or more events are detected by the hardware. Each event is independently maskable by setting the DSS.[DISPC\\_IRQENABLE](#) register.

To check when a particular interrupt event occurs and to reset a particular event, the DSS.[DISPC\\_IRQSTATUS](#) register must be accessed. This register regroups all the status of the module internal events that generate an interrupt (read 0: No interrupt occurred; read 1: Interrupt occurred; write 1: Status bit reset). See [Section 7.7, Display Subsystem Register Manual](#), for more information on checking and clearing interrupt events.

[Table 7-22](#) lists the display subsystem interrupt events.

**Table 7-22. Display Subsystem Interrupts**

| Interrupt Name             | Description                                                                                                                              |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| FRAMEDONE                  | Active frame is complete and LCD output is disabled.                                                                                     |
| VSYNC                      | VSYNC interrupt occurred at the end of the frame.                                                                                        |
| EVSYNC_EVEN <sup>(1)</sup> | EVSYNC_EVEN interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is even.)                             |
| EVSYNC_ODD <sup>(1)</sup>  | EVSYNC_ODD interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is odd.)                               |
| ACBIASCOUNTSTATUS          | The ac-bias transition counter decremented to 0.                                                                                         |
| PROGRAMMEDLINENUMBER       | The LCD reached the user-programmed line number.                                                                                         |
| GFXFIFOUNDERFLOW           | The input graphics FIFO goes underflow.                                                                                                  |
| GFXENDWINDOW               | The screen reached the end of the graphics window. All data for the graphics window are fetched from memory and displayed on the screen. |
| PALETTEGAMMALOADING        | The palette/gamma table is loaded.                                                                                                       |
| OCPERROR                   | L3 interconnect sent SResp = ERR.                                                                                                        |
| VID1FIFOUNDERFLOW          | The input video1 FIFO goes underflow.                                                                                                    |

<sup>(1)</sup> EVYNC interrupts (EVSYNC\_EVEN and EVSYNC\_ODD) are external interrupts received by the display controller and generated by the video encoder (VENC) module.

**Table 7-22. Display Subsystem Interrupts (continued)**

| Interrupt Name    | Description                                                                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VID1ENDWINDOW     | The screen reached the end of video1 window. All data for the video window are fetched from the memory and displayed on the screen.                                                                  |
| VID2FIFOUNDERFLOW | The input video2 FIFO goes underflow.                                                                                                                                                                |
| VID2ENDWINDOW     | The screen reached the end of video2 window. All data for the video window are fetched from the memory and displayed on the screen.                                                                  |
| SYNCLOST          | Interrupt occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).                                                                            |
| SYNCLOSTDIGITAL   | Interrupt occurs when the display controller is not ready to output data when a digital request occurs. This interrupt informs that the timings of the NTSC/PAL video encoder are not set correctly. |
| WAKEUP            | Occurs when the wakeup signal is asserted                                                                                                                                                            |

**NOTE:** To clear a synchronization lost interrupt, follow this sequence:

1. Clear the DSS.DISPC\_CONTROL[0] LCDENABLE (LCD: SYNCLOST interrupt) or DSS.DISPC\_CONTROL[1] DIGITALENABLE (TV: SYNCLOSTDIGITAL interrupt) bits.  
Check the interrupts.  
LCD: Verify that a FRAMEDONE interrupt occurs.  
TV : Verify that EVSYNC\_EVEN or EVSYNC\_ODD interrupts occur.
2. Set the DSS.DSS\_SYSCONFIG[1] SOFTRESET bit to reset the display subsystem.
3. Set the display subsystem registers again.

**NOTE:** The SYNCLOSTDIGITAL interrupts, which occur before the first VSYNC pulse signal (from the video encoder), must not be considered.

After the first VSYNC pulse signal, the SYNCLOSTDIGITAL interrupt status bit must be cleared by writing 1 in the DSS.DISPC\_IRQSTATUS[15] SYNCLOSTDIGITAL bit; then the SYNCLOSTDIGITAL interrupt can be enabled by setting the DSS.DISPC\_IRQENABLE[15] SYNCLOSTDIGITAL bit.

### 7.3.2.2 DSI Interrupt Request

The DSI protocol engine requires a single interrupt line, DSI\_IRQ. The DSS.DSI\_IRQSTATUS register indicates the general interrupt events. See [Table 7-23](#). Each VC and complex I/O has a dedicated interrupt register: DSS.DSI\_VCn\_IRQSTATUS and DSS.DSI\_COMPLEXIO\_IRQSTATUS respectively. See [Table 7-24](#) and [Table 7-25](#).

[Table 7-23](#) indicates the DSI global interrupt events.

**Table 7-23. DSI Global Interrupts**

| Interrupt Name        | Description                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------|
| RESYNCHRONIZATION_IRQ | Resynchronization in video mode                                                                                  |
| TA_TO_IRQ             | Turn-around timer expired                                                                                        |
| LDO_POWER_GOOD_IRQ    | Signal LDOPWRGOOD from the DSI_PHY changes its state for the supply VDDALDODSIPLL from up to down or down to up. |
| SYNC_LOST_IRQ         | Synchronization with video mode port is lost (video mode only)                                                   |
| ACK_TRIGGER_IRQ       | Acknowledge trigger is received                                                                                  |
| TE_TRIGGER_IRQ        | Tearing effect trigger is received                                                                               |
| WAKEUP_IRQ            | Occurs when the SWakeUp signal is asserted                                                                       |
| HS_TX_TO_IRQ          | High speed TX Time-out Interrupt                                                                                 |
| LP_RX_TO_IRQ          | Low speed RX Time-out Interrupt                                                                                  |

**Table 7-23. DSI Global Interrupts (continued)**

| Interrupt Name       | Description                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COMPLEXIO_ERR_IRQ    | Error signaling from complex I/O: The interrupt is triggered when any error is received from the complex I/O (events are defined in <a href="#">DSI_COMPLEXIO_IRQSTATUS</a> ).                              |
| PLL_RECAL_IRQ        | PLL recal event (assertion of DSIRECAL signal from the DSI PLL Control module)                                                                                                                              |
| PLL_UNLOCK_IRQ       | PLL unlock event (deassertion of DSILock signal from the DSI PLL Control module)                                                                                                                            |
| PLL_LOCK_IRQ         | PLL lock event (assertion of DSILock signal from the DSI PLL Control module)                                                                                                                                |
| VIRTUAL_CHANNEL3_IRQ | Virtual channel #3<br>Error signaling from DSI Virtual Channel3: The interrupt is triggered when an error is received from DSI Virtual Channel3 (events are defined in <a href="#">DSI_VC3_IRQENABLE</a> ). |
| VIRTUAL_CHANNEL2_IRQ | Virtual channel #2<br>Error signaling from DSI Virtual Channel2: The interrupt is triggered when an error is received from DSI Virtual Channel2 (events are defined in <a href="#">DSI_VC2_IRQENABLE</a> ). |
| VIRTUAL_CHANNEL1_IRQ | Virtual channel #1<br>Error signaling from DSI Virtual Channel1: The interrupt is triggered when an error is received from DSI Virtual Channel1 (events are defined in <a href="#">DSI_VC1_IRQENABLE</a> ). |
| VIRTUAL_CHANNEL0_IRQ | Virtual channel #0<br>Error signaling from DSI Virtual Channel0: The interrupt is triggered when an error is received from DSI Virtual Channel0 (events are defined in <a href="#">DSI_VC0_IRQENABLE</a> ). |

[Table 7-24](#) indicates the DSI complex I/O interrupt events.

**Table 7-24. DSI Complex I/O Interrupts**

| Interrupt Name         | Description                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------|
| ULPSActiveNot_ALL0_IRQ | All signals ULPSActiveNOT are 0                                                              |
| ULPSActiveNot_ALL1_IRQ | All the ULPSActiveNOT signals corresponding to the lanes with TXULPSExit being high are high |
| STATEULPS3_IRQ         | Lane #3 in ultralow-power state                                                              |
| STATEULPS2_IRQ         | Lane #2 in ultralow-power state                                                              |
| STATEULPS1_IRQ         | Lane #1 in ultralow-power state                                                              |
| ERRCONTROL3_IRQ        | Control error for lane #3                                                                    |
| ERRCONTROL2_IRQ        | Control error for lane #2                                                                    |
| ERRCONTROL1_IRQ        | Control error for lane #1                                                                    |
| ERRESC3_IRQ            | Escape entry error for lane #3(edge trigger interrupt)                                       |
| ERRESC2_IRQ            | Escape entry error for lane #2 (edge trigger interrupt)                                      |
| ERRESC1_IRQ            | Escape entry error for lane #1 (edge trigger interrupt)                                      |
| ERRCONTENTIONLP1_1_IRQ | Contention LP1 error for lane #1                                                             |
| ERRCONTENTIONLP0_1_IRQ | Contention LP0 error for lane #1                                                             |
| ERRCONTENTIONLP1_2_IRQ | Contention LP1 error for lane #2                                                             |
| ERRCONTENTIONLP0_2_IRQ | Contention LP0 error for lane #2                                                             |
| ERRCONTENTIONLP1_3_IRQ | Contention LP1 error for lane #3                                                             |
| ERRCONTENTIONLP0_3_IRQ | Contention LP0 error for lane #3                                                             |
| ERRSYNCESC3_IRQ        | Low power Data transmission synchronization error for lane #3                                |
| ERRSYNCESC2_IRQ        | Low power Data transmission synchronization error for lane #2                                |
| ERRSYNCESC1_IRQ        | Low power Data transmission synchronization error for lane #1                                |

**NOTE:** The error contention signals for DX and DY signals of each lane are ORed together.

**Table 7-25** indicates the DSI VCs interrupt events

**Table 7-25. DSI Virtual Channel Interrupts**

| Interrupt Name        | Description                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ECC_CORRECTION_IRQ    | Indicates if a 1-bit error correction occurred using the ECC                                                                                                                    |
| PACKET_SENT_IRQ       | Indicates that a packet has been sent. It is used when BTA manual mode is used                                                                                                  |
| CS_IRQ                | Virtual channel - Check-Sum of the payload mismatch detection                                                                                                                   |
| FIFO_RX_OVF_IRQ       | RX FIFO overflow. The FIFO used on the L4 interconnect slave port for buffering the data received on the DSI link has overflowed                                                |
| FIFO_TX_OVF_IRQ       | TX FIFO overflow. The FIFO used on the L4 interconnect slave port for buffering the data received on the L4 interconnect slave port has overflowed                              |
| BTA_IRQ               | Bus turnaround is received from the peripheral (the VC ID used for the last BTA request transfer to the peripheral is used to determine which VC is used to flag the interrupt) |
| ECC_NO_CORRECTION_IRQ | ECC error (short and long packets). No correction of the header because of more than 1-bit error                                                                                |
| FIFO_TX_UDF_IRQ       | TX FIFO underflow. The FIFO used on the slave port for buffering the data received on the L4 interconnect port has under-flowed in the middle of a packet transfer              |

## 7.4 Display Subsystem Functional Description

This section describes the functions of the LCD and TV display supports by describing the following modules: display controller, DSI protocol engine, DSI PLL controller, DSI complex I/O, RFBI and video encoder.

The functions of the display controller are common to both LCD and TV data paths; the RFBI are LCD-specific; and the video encoder functions are specific to the TV set.

### 7.4.1 Block Diagram

[Figure 7-67](#) is a schematic of the display subsystem.

**Figure 7-67. Display Subsystem Full Schematic**

dss-037

### 7.4.2 Display Controller Functionalities

The display controller can read and display the encoded pixel data stored in memory (see [Figure 7-68](#)).

**Figure 7-68. Display Controller Architecture Overview**

dss-038

Several processes can be configured to manage the graphics pipeline (palette, gamma table correction) and video pipeline (color space conversion, upsampling, downsampling, overlay, and transparency features).

The internal timing generator logic generates the LCD input signals. The external timing generator generates the appropriated signals to drive the digital output. The data from the two overlay managers are sent on the two concurrent 24-bit buses outside the display controller module. The memory accessed by the display controller is either the SDRAM memory or the SRAM memory.

## 7.4.2.1 Display Modes

### 7.4.2.1.1 LCD Output

The display subsystem supports two types of display technologies (both monochrome and color modes):

- Passive matrix displays
- Active matrix displays

The passive matrix display mode supports 3375 possible colors, allowing 16, 256, or 3375 colors to be displayed in each frame, depending on the color depth. The monochrome LCD has 15 grayscale levels available.

In active matrix display mode, the configuration of colors depends on the color depth:

- 24 BPP supports 16,777,216 colors.
- 18 BPP supports 262,144 colors.
- 16 BPP supports 65,536 colors.
- 12 BPP supports 4096 colors.

### 7.4.2.1.2 Digital Output

The digital output is always a 24-bit RGB value based on an external pixel request.

## 7.4.2.2 Graphics Pipeline

The graphics pipeline is connected to the graphics FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of one 256-entry palette and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the most-significant bits [MSBs] for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the graphics pipeline is the replication logic used for RGB pixels, then the second unit is the palette for concerned pixels.

### 7.4.2.2.1 Graphics Memory Format

The supported formats for the graphics layer are CLUT bitmaps (1-, 2-, 4-, and 8-BPP) and true color bitmaps in RGB formats (12-, 16-, and 24-BPP [packet and nonpacket RGB24]) and in ARGB or RGBA formats (ARGB 16-, and 32-BPP, and RGBA 32-BPP) as follows:

- BITMAP 1-BPP data memory organization (CLUT) (little endian)

- BITMAP 1-BPP data memory organization (CLUT) (little endian + nibble mode)

- BITMAP 1-BPP data memory organization (CLUT) (big endian)

- BITMAP 1-BPP data memory organization (CLUT) (big endian + nibble mode)

- BITMAP 2-BPP data memory organization (CLUT) (little endian)

dss-T041

- BITMAP 2-BPP data memory organization (CLUT) (little endian + nibble mode)

dss-T042

- BITMAP 2-BPP data memory organization (CLUT) (big endian)

dss-T062

- BITMAP 2-BPP data memory organization (CLUT) (big endian + nibble mode)

dss-T063

- BITMAP 4-BPP data memory organization (CLUT) (little endian)

dss-T043

- BITMAP 4-BPP data memory organization (CLUT) (little endian + nibble mode)

**7.4.2.2.2 Color Look-Up Table/Gamma Table**

The graphics path supports the palette/gamma table. [Figure 7-69](#) shows the internal architecture of the color look-up/gamma table.

The palette is split into three memories of 256-bit x 8-bit entries. For bitmap (CLUT) indexes, the same value (1-, 2-, 4-, or 8-BPP) indexes the three memories. For gamma curve correction, each R, G, and B component indexes the corresponding memory to combine the three gamma curve values into a 24-bit value. The table can be reloaded every frame, once or never (at the beginning of the frame before fetching the pixels for the graphics and/or video windows).

**Figure 7-69. Palette/Gamma Correction Architecture**

#### 7.4.2.2.2.1 Color Look-Up Table

The palette mode uses the encoded pixel values from the input graphics FIFO as pointers to index the 24-bit-wide palette: 1-BPP pixels address 2 palette entries, 2-BPP pixels address 4 palette entries, 4-BPP pixels address 16 palette entries, and 8-BPP pixels address 256 palette entries.

When a palette entry is selected by the encoded pixel value, the content of the entry is sent to the color/grayscale space/time base passive matrix dithering circuit, or to the color time base active matrix dithering circuit.

In color mode, the value within the palette is made up of three 8-bit fields, one for each color component (red, green, and blue). For color operation, an individual frame is limited to a selection of 256 colors (the number of palette entries). The format of one of the palette values in the memory is as follows:

- 24-BPP Data Memory Organization (Little Endian or Nibble)

|                         |                         |                       |                 |
|-------------------------|-------------------------|-----------------------|-----------------|
| 31 30 29 28 27 26 25 24 | 23 22 21 20 19 18 17 16 | 15 14 13 12 11 10 9 8 | 7 6 5 4 3 2 1 0 |
| Unused                  | R                       | G                     | B               |

In monochrome mode, only one 8-bit value is present.

- 24-BPP Data Memory Organization (Little Endian or Nibble)

|                         |                         |                       |                 |
|-------------------------|-------------------------|-----------------------|-----------------|
| 31 30 29 28 27 26 25 24 | 23 22 21 20 19 18 17 16 | 15 14 13 12 11 10 9 8 | 7 6 5 4 3 2 1 0 |
| Unused                  | Unused                  | Unused                | Gray            |

After passing through the palette, 256 gray scales and 16,777,216 colors are numbers obtained. A redundancy introduced in the dithering logic step reduces these numbers when displaying. For passive matrix panels, the colors are limited to 15 gray scales and 3375 colors.

- Passive matrix technology  
The palette is bypassed in 12, 16, and 24 BPP. The palette is not used.
- Active matrix technology

The palette is bypassed in 12, 16, and 24 BPP, allowing up to  $2^{24} = 16,777,216$  colors to be displayed.

#### 7.4.2.2.2.2 Gamma Table

In the gamma curve mode, the selected encoded pixel values based on the color keys from the video or graphics paths are sent to the gamma curve table. The mode is available only if the color look-up palette is not used for graphics. The output of the gamma curve processing is always sent to the LCD output. It is not available on digital output.

Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to an R, G, or B component. The format of one of the gamma curve values in the memory is as follows:

- 24-BPP Data Memory Organization (Little or Big Endian)

|                         |                         |                       |                 |
|-------------------------|-------------------------|-----------------------|-----------------|
| 31 30 29 28 27 26 25 24 | 23 22 21 20 19 18 17 16 | 15 14 13 12 11 10 9 8 | 7 6 5 4 3 2 1 0 |
| Unused                  | Gamma-R                 | Gamma-G               | Gamma-B         |

#### 7.4.2.2.2.2.1 Replication Logic

The replication logic increases the color depth of the graphics and video encoded pixels (from true color RGB 12-, and 16-BPP to 24-BPP). The encoded value is shifted to the 24-bit alignment. The MSB bits are copied to the LSB missing ones. Then the graphics are merged with the video data based on the transparency color keys. When the replication logic is not selected, the encoded pixel values are shifted to the MSB boundary of the 24-bit format. The missing bit values are filled up with 0s.

This is an example for RGB16 extension:

- Original 16-BPP data:

|                                                     |
|-----------------------------------------------------|
| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0               |
| R4 R3 R2 R1 R0   G5 G4 G3 G2 G1 G0   B4 B3 B2 B1 B0 |

dss-T055

- If replication logic is ON:

|                                                                                   |                                       |
|-----------------------------------------------------------------------------------|---------------------------------------|
| 23 22 21 20 19 18 17 16                                                           | 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
| R4 R3 R2 R1 R0 R4 R3 R2   G5 G4 G3 G2 G1 G0 G5 G4   B4 B3 B2 B1 B0 B4 B3 B2 B1 B0 |                                       |

dss-T056

- If replication logic is OFF:

|                                                                     |                                       |
|---------------------------------------------------------------------|---------------------------------------|
| 23 22 21 20 19 18 17 16                                             | 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
| R4 R3 R2 R1 R0 0 0 0   G5 G4 G3 G2 G1 G0 0 0   B4 B3 B2 B1 B0 0 0 0 |                                       |

dss-T057

#### 7.4.2.3 Video Pipeline

The video pipeline is connected to the video FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of the Re-Sampling unit, the Color Space Conversion Unit, and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the MSBs for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the video pipeline is the Re-Sampling Unit, then the replication logic used for RGB pixels, then the Color Space Conversion Unit for YUV4:2:2 pixels.

#### 7.4.2.3.1 Video Memory Formats

The display subsystem supports the following formats for the video layer: YUV2, UYVY, RGB12, RGB16, RGB24 (non-packed and packed formats), ARGB16 (video channel 2 only), ARGB32 (video channel 2 only), and RGBA32 (video channel 2 only).

- RGB 12-BPP data memory organization (little endian)

- RGB 12-BPP data memory organization (big endian)

- RGB 16-BPP data memory organization (little endian)

- RGB 16-BPP data memory organization (big endian)

- ARGB 16-BPP data memory organization (little endian + video 2 channel only)

- ARGB 16-BPP data memory organization (big endian + video 2 channel only)

- RGB 24-BPP data memory organization (little or big endian)

- RGB 24-BPP packet data memory organization (little or big endian)

- ARGB 32-BPP data memory organization (little or big endian + video 2 channel only)

- RGBA 32-BPP data memory organization (little or big endian + video 2 channel only)

- UYVY 4:2:2 data memory organization (little endian)

- UYVY 4:2:2 data memory organization (big endian)

- YUV2 4:2:2 data memory organization (little endian)

- YUV2 4:2:2 data memory organization (big endian)

#### 7.4.2.3.2 Color Space Conversion

The color space conversion module converts the video-encoded pixel values from YCbCr 4:2:2 format into RGB24. [Figure 7-70](#) and [Figure 7-71](#) detail the YCbCr 4:2:2 conversion to YCbCr 4:4:4 depending on the rotation parameters.

**Figure 7-70. YCbCr 4:2:2 to YCbCr 4:4:4 (0- or 180-Degree Rotation)**

**Figure 7-71. YCbCr 4:2:2 to YCbCr 4:4:4 (90- or 270-Degree Rotation)**

The interpolation of the missing chrominance component is given by the equation in [Figure 7-72](#).

**Figure 7-72. Interpolation of the Missing Chrominance Component**

$$C_{b,n}(\text{YCbCr 444}) = \frac{C_{b,n-1}(\text{YCbCr 422}) + C_{b,n+1}(\text{YCbCr 422})}{2} \quad (\text{n odd})$$

$$C_{r,n}(\text{YCbCr 444}) = \frac{C_{r,n-1}(\text{YCbCr 422}) + C_{r,n+1}(\text{YCbCr 422})}{2} \quad (\text{n odd})$$

dss-E062

First, to convert the YCbCr 4:2:2 encoded pixel values into YCbCr 4:4:4 format, the missing chrominance samples (Cb and Cr) are interpolated using the average values of the two closest values on the same line (1/2, 1/2) or are repeated from the second pixel in the same 32-bit container.

- In case of rotation 0-degree, for the last pixel, the chrominance samples are duplicated using the values from the previous pixel; otherwise, the chrominance samples are averaged using the two adjacent values.

- In case of 180-degree rotation, for the first pixel the chrominance samples missing are duplicated from the adjacent pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of rotation 90- and 270-degree, the missing chrominance components are duplicated from the adjacent pixel in the same 32-bit container.

In case of 5-tap configuration for the vertical filtering, the missing chrominance samples are always duplicated using the second chrominance samples in the same 32-bit value.

Then the pixels are converted from YCbCr color space into the RGB color space, because the output format of the color space conversion is RGB24 (8-bit value per component: Red, green, and blue). The following matrices show the 11-bit coefficients registers used to convert from YCbCr 4:4:4 into RGB24. Users set the coefficients according to the standard used to encode the pixel data in YCbCr color space.

In case of resampling, the YUV4:2:2 format is converted into YUV4:4:4. The YUV4:2:2-to-YUV4:4:4 processing is bypassed in the color space conversion unit.

If the active range for the luminance samples (Y) is [16:235] and [16:240] for the chrominance samples (Cb and Cr), the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 7-73](#) gives the 11-bit coefficients of the YCbCr to RGB color space conversion.

**Figure 7-73. YCbCr to RGB Registers (VIDFULLRANGE = 0)**

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E063

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:255], the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 7-74](#) gives the 11-bit coefficients of the YCbCr-to-RGB color space conversion.

**Figure 7-74. YCbCr to RGB Registers (VIDFULLRANGE = 1)**

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E064

[Figure 7-75](#) describes the computation for the calculation of the R component. The same computation applies for the G and B components:

**Figure 7-75. Color Space Conversion Macro-Architecture**

dss-065

#### 7.4.2.3.3 Hardware Cursor

The video layer can be used to display the hardware cursor. The encoded pixel data for the cursor image are in RGB12, RGB16 or RGB24 formats and the color space conversion block is bypassed. The transparency color key can be used when a non rectangle shape is used.

The alpha blending can be used to show a partial transparent cursor. When the alpha blender is enabled, the graphics layer is on top of the video layers. The cursor uses the graphics layer. The pixel alpha blending or the transparency color key can be used.

#### 7.4.2.3.4 Up-/Down-Sampling

The video layer has a dedicated resizing block to upsample and downsample the video-encoded pixels. The supported input formats from memory are RGB24, RGB16, and YUV4:2:2

(RGB12 and all the alpha formats like ARGB and RGBA are not supported)

Users must set the right size and position of the original video before resizing for the upsampled/downsampled video to be inside the display screen boundaries.

The filtering applies on each component independently R, G, and B).

For the horizontal up/downsampling, the equation is R component with five taps):

$$R_{out}(n) = \left( \sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7 \quad (7)$$

dsse-066

For the vertical up/downsampling, the equation is R component with three taps):

$$Rout(n) = \left( \sum_{i=-1}^{i=1} C_i(\Phi) \times Rin(n+i) \right) \gg 7 \quad (8)$$

dss-E067

For the vertical up/downsampling, the equation is R component with five taps:

$$Rout(n) = \left( \sum_{i=-2}^{i=2} C_i(\Phi) \times Rin(n+i) \right) \gg 7 \quad (9)$$

dss-E068

*Rout*: R component output

*Ci*( $\Phi$ )  
dss-E069 : FIR filter coefficients

*Rin*: R component input

The pixel (n + 1) is older than pixel (n). The line (n + 1) is older than line (n).

---

**NOTE:** The coefficients Ci() depend on the phase between input and output pixels.

---

**NOTE:** If the 5-tap resizer is used for RGB16 and YUV4:2:2 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels:

[DISPC\\_VIDn\\_ATTRIBUTES\[21\]](#) VIDVERTICALTAPS == 1

[DISPC\\_VIDn\\_PICTURE\\_SIZE\[10:0\]](#) VIDORGSIZEX 4 and even

---

Figure 7-76 shows an example of video upsampling.

**Figure 7-76. Video Upsampling**

dss-070

### **Filter Description**

The up/downsampling filter is a poly-phase filter with five taps and eight phases for the horizontal filter and a programmable number of taps (three or five) and eight phases for vertical filter. The upsampling ratio is up to x8. The downsampling ratio using 3-tap configuration is 2. The downsampling ratio using 5-tap configuration is 4. The vertical filter is first applied to the encoded input pixel data; and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. [Figure 7-77](#) shows the computation for the R component in the case of three coefficients (vertical filtering). The same computation applies to the G and B components.

**Figure 7-77. Resampling Macro-Architecture (3-Coefficient Processing)**

dss-071

To determine if the minimum functional clock matches the down sampling ratio and the desired Pixel clock, the following formula must be used in conjunction with [Table 7-26](#) and [Table 7-27](#).

#### Ratio V when performing a vertical down-sampling only

$$h\_ratio = \frac{DISPC\_SIZE\_LCD.PPL}{DISPC\_VID\_SIZE.VidSizeX}$$

$$v\_ratio = \frac{DISPC\_VID\_PICTURE\_SIZE.VidOrgSizeY}{DISPC\_VID\_SIZE.VidSizeY}$$

$$Ratio = \frac{v\_ratio}{2 \times h\_ratio} \quad If \quad 1 < v\_ratio \leq 2$$

$$Ratio = \max\left(\frac{v\_ratio}{2 \times h\_ratio}, \frac{v\_ratio - 2}{2 \times (h\_ratio - 1)}\right) \quad If \quad 2 < v\_ratio \leq 4$$

dss\_swpu108-E135

**NOTE:** For frequency ratio calculation on the TV output, it is correct to replace [DISPC\\_SIZE\\_LCD](#) with [DISPC\\_SIZE\\_DIG](#).

When the down-sampling ratio is below 0.5, it is not possible to use a video in full screen.

#### Ratio H when performing a horizontal down-sampling only

$$Ratio = \frac{DISPC\_VID\_PICTURE\_SIZE.VidOrgSizeX}{DISPC\_VID\_SIZE.VidSizeX}$$

dss\_swpu108-E136

#### Ratio H+V when performing a horizontal and vertical down-sampling

Ratio = max (horizontal Ratio, vertical Ratio) as previously defined.

**Table 7-26. Functional Clock Frequency Requirement in RGB16 YUV4:2:2—Active Matrix Display**

| Minimum Functional Clock (MHz) |                  | Horizontal Resampling |            |            |            |            |
|--------------------------------|------------------|-----------------------|------------|------------|------------|------------|
|                                |                  | Off                   | Up         | 1:1 – 1:2  | 1:2 – 1:3  | 1:3 – 1:4  |
| Vertical Resampling            | Off              | AxPCLK                | AxPCLK     | 2xPCLK     | 3xPCLK     | 4xPCLK     |
|                                | Up               | AxPCLK                | AxPCLK     | 2xPCLK     | 3xPCLK     | 4xPCLK     |
|                                | 3-tap 1:1 to 1:2 | 2xPCLK                | 2xPCLK     | 4xPCLK     | 6xPCLK     | 8xPCLK     |
|                                | 5-tap 1:1 to 1:4 | RatioxPCLK            | RatioxPCLK | RatioxPCLK | RatioxPCLK | RatioxPCLK |

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

**Table 7-27. Functional Clock Frequency Requirement in RGB24—Active Matrix Display**

| Minimum Functional Clock (MHz) |                  | Horizontal Resampling |            |              |              |              |
|--------------------------------|------------------|-----------------------|------------|--------------|--------------|--------------|
|                                |                  | Off                   | Up         | 1:1 – 1:2    | 1:2 – 1:3    | 1:3 – 1:4    |
| Vertical Resampling            | Off              | AxPCLK                | AxPCLK     | 2xPCLK       | 3xPCLK       | 4xPCLK       |
|                                | Up               | AxPCLK                | AxPCLK     | 2xPCLK       | 3xPCLK       | 4xPCLK       |
|                                | 3-tap 1:1 to 1:2 | 2xPCLK                | 2xPCLK     | 4xPCLK       | 6xPCLK       | 8xPCLK       |
|                                | 5-tap 1:1 to 1:4 | RatioxPCLK            | RatioxPCLK | 2xRatioxPCLK | 2xRatioxPCLK | 2xRatioxPCLK |

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

**Use case example:**

An input picture of 1024\*768 is scaled to an output picture of size of 800\*600 and displayed onto a LCD of resolution 1280\*768 at a PCLK of 74.25 MHz with a DSS functional clock of 133 MHz.

In this example, a H+V down-sampling is done on the input picture. Firstly the Ratio V and H are determined and the resulting maximum value is taken to calculate the functional clock frequency required.

**Ratio V:** h\_ratio = 1.6 and v\_ratio = 1.28 then Ratio = 0.4

**Ratio H:** Ratio = 1.28

**Ratio H+V:** Ratio = max (1.28, 0.4) = 1.28

In this use case, the horizontal and vertical down sampling range are 1:1–1:2. The 3-tap or 5-tap configuration can be taken into consideration. Therefore, from [Table 7-26](#) and [Table 7-27](#), If in RGB16-YUV4:2:2:

- 3-taps → DSS functional clock = 4 \* PCLK = 297 MHz
- 5-taps → DSS functional clock = Ratio \* PCLK = 95.36 MHz

If in RGB24,

- 3-taps → DSS functional clock = 4 \* PCLK = 297 MHz
- 5-taps → DSS functional clock = 2 \* Ratio \* PCLK = 190.72 MHz

In this use case, the pixel format supported is RGB16-YUV4:2:2 in a 5-tap configuration.

#### 7.4.2.4 Overlay Support

**CAUTION**

Enabling overlay optimization (setting the DSS.DISPC\_CONTROL [12] OVERLAYOPTIMIZATION bit) if no overlay region effectively exists (the DSS.DISPC\_VIDn\_ATTRIBUTES [0] VIDENABLE bit is cleared, with n = 1, 2) leads to unpredictable behavior. The overlay optimization feature must be enabled only when an overlay area exists. Before enabling the overlay optimization, the DSS.DISPC\_GFX\_WINDOW\_SKIP[31:0] GFXWINDOWSKIP bit field must be first set according to the video1 and graphics windows overlap.

The overlay mechanism consists of displaying more than one layer (graphics and video layers) using rules based on priority and transparency color keys.

When the pixel format is ARGB or RGBA, the color key match logic uses only the RGB value defined by ARGB or RGBA. The alpha blending factor is ignored.

The overlay managers are based on the same rules for priority and transparency color keys (see [Figure 7-80](#)).

Each data pipeline is assigned a single overlay related to a single display controller output.

The overlay manager is connected to all three outputs of the pipelines (graphics, video1 and video2). The output of the LCD overlay manager is connected to the Spatial/Temporal Dithering, and Passive Matrix units and back to the palette unit in the case of Gamma correction.

##### 7.4.2.4.1 Priority Rule

The overlay manager can be configured in two distinct modes:

- Alpha mode (only source color key with the graphics layer)
- Normal mode (no alpha support)

The following rules apply in normal mode:

The video1 layer is always on top of the graphics layer. The video2 layer is always on top of the video1 and graphics. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 7-82](#)).

**Figure 7-78. Overlay Manager in Normal Mode**

dss-072

**Figure 7-79. Display Attributes in Normal Mode**

dss-073

The following rules apply in alpha mode:

The video2 layer is always on top of the video1 layer. The graphics layer is always on top of the video1 and video2. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see Figure 7-82).

**Figure 7-80. Overlay Manager in Alpha Mode**

dss-163

**Figure 7-81. Display Attributes in Alpha Mode**

dss-164

Figure 7-82 shows the alpha blending processing in detail.

**Figure 7-82. Alpha Blending Macro Architecture with Pre-multiplied Alpha Support**

**NOTE:** "1-alpha" operator corresponds to the basic 1's complement operation.

The pre-multiplied alpha option is accessible through DSS.[DISPC\\_GFX\\_ATTRIBUTES\[28\]](#) PREMULTIPLYALPHA and DSS.[DISPC\\_VIDn\\_ATTRIBUTES\[28\]](#) PREMULTIPLYALPHA registers bits. The following settings are available:

- PREMULTIPLYALPHA bit = '0' : Source is not pre-multiplied with alpha. Full blending is done in the DISPC.
- PREMULTIPLYALPHA bit = '1' : Source is pre-multiplied with alpha. Partial blending is done.

---

**NOTE:** The pre-multiplied alpha option is only valid when bit fields DSS.DISPC\_GFX\_ATTRIBUTES[4:1] GFXFORMAT and DSS.DISPC\_VIDn\_ATTRIBUTES[4:1] VIDFORMAT, respectively, are set to ARGB or RGBA formats. Otherwise, the PREMULTIPLYALPHA bit fields are ignored by the hardware.

---

The alpha blending value is defined by the pixel value (ARGB or RGBA formats). A global alpha blending value can be defined and used in combination with the pixel alpha blending value. If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF.

In case of ARGB-444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value. [Table 7-28](#) details the alpha blending 4-bit values and the corresponding blending percentage.

**Table 7-28. Alpha Blending 4-Bit Values**

| Alpha Blending 4-Bit Value (ARGB-444) | Alpha Blending 8-Bit Value<br>(Converted Value) | % Blending         |
|---------------------------------------|-------------------------------------------------|--------------------|
| 0x0                                   | 0x00                                            | 100% (transparent) |
| 0x1                                   | 0x11                                            | 93.33%             |
| 0x2                                   | 0x22                                            | 86.6%              |
| ...                                   | ...                                             | ...                |
| 0xE                                   | 0xEE                                            | 6.6%               |
| 0xF                                   | 0xFF                                            | 0% (opaque)        |

#### 7.4.2.4.2 Transparency Color Keys

##### 7.4.2.4.2.1 Normal Mode

This section describes the features available in normal mode.

The two transparency color keys are the video source transparency color key and the graphics destination transparency color key. The encoded pixel color value is compared to the transparency color key. For CLUT bitmaps, the palette index is compared to the transparency color key and not to the palette value pointed out by the palette index.

---

**NOTE:** The video source transparency color key and graphics destination transparency color key cannot be active at the same time.

---

- Video source transparency color key value:

The video source transparency color key value defines the encoded pixel data considered as the transparent pixel. The encoded pixel values with the source color key value are pixels not visible on the screen, and the underlayer encoded pixel values or solid background color are visible.

The video source transparency color key can be used only if the color space conversion and the up/down-scaling modules are disabled. The format of the data is RGB 16. (This feature handles the hardware cursor displayed by one of the video layers.)

To enable the video source transparency color key, set to 0x1 the DSS.DISPC\_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC\_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC\_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC\_CONFIG[12] TCKDGENABLE bit (digital output) to enable or disable the transparency color key.

An example is shown in [Figure 7-83](#): The video source transparency is applied on video1 (VID1) and video2 (VID2) layers. The pixels with the transparency color key are not displayed; instead, underlying

layers are shown.

**Figure 7-83. Video Source Transparency Example**

dss-074

- Graphics destination transparency color key value:

The graphics destination transparency color key value defines the encoded pixels in the video layers to be displayed. The encoded pixel values with the destination color key value are pixels not visible on the screen and the pixels different from the transparency color key are displayed over the video layers. The destination transparency color key is applicable only in the graphics region when graphics and video overlap; otherwise, the destination transparency color key is ignored.

To enable the graphics destination transparency color key, set to 0x0 the DSS.[DISPC\\_CONFIG\[11\]](#) TCKLCDSELECTION bit for LCD output or the DSS.[DISPC\\_CONFIG\[13\]](#) TCKDIGSELECTION bit for digital output. Program the DSS.[DISPC\\_CONFIG\[10\]](#) TCKLCDENABLE bit (LCD output) or the DSS.[DISPC\\_CONFIG\[12\]](#) TCKDIGINABLE bit (digital output) to enable or disable the transparency color key.

An example is shown in [Figure 7-84](#): The destination transparency is applied on graphics (GFX) layer and the pixels without the transparency color key are displayed over the overlying layers.

**Figure 7-84. Graphics Destination Transparency Example**

dss-075

#### 7.4.2.4.2.2 Alpha Mode

This section describes the features available in alpha mode.

Only the graphics source transparency color key is available. The encoded graphics pixel color value is compared to the transparency color key. The encoded pixel values with the source transparency key are not visible and the under-layer encoded pixel values or solid background color are visible. To enable the graphics source transparency color key, set to 0x0 the DSS.[DISPC\\_CONFIG\[11\]](#) TCKLCDSELECTION bit for LCD output or the DSS.[DISPC\\_CONFIG\[13\]](#) TCKDIGSELECTION bit for digital output. Program the DSS.[DISPC\\_CONFIG\[10\]](#) TCKLCENABLE bit (LCD output) or the DSS.[DISPC\\_CONFIG\[12\]](#) TCKDGENABLE bit (digital output) to enable or disable the transparency color key. In the case of CLUT bit maps, the palette index is compared to the transparency color key and not the palette value pointed out by the palette index.

#### 7.4.2.4.3 Overlay Optimization (Only Available in Normal Mode)

The display controller can be configured to take advantage of the fact that the graphics pixels under video window 1 are not visible when the transparency color key is not used. The optimization can be selected to reduce the bandwidth used to fetch the pixels for graphics. The color key must be disabled. The graphics pixels under the video window 1 are not fetched from system memory. At least the video window 1 and the graphics window must be enabled. The following graphic formats are supported: RGB (RGB16 and RGB24 packed and unpacked), YUV4:2:2, and BITMAP 8. The formats BITMAP 1, 2, and 4 are not supported. The video format can be RGB (RGB16, RGB24 packed and unpacked, and YUV4:2:2 formats). The DMA engine does not fetch the unnecessary graphics pixels to avoid extra bandwidth use. Only visible pixels from graphics and video buffers in system memory are fetched and displayed by the display controller.

#### 7.4.2.5 Active/Passive Matrix Display Data Path

For active matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Multiple cycle data format

For passive matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation

- Spatial/temporal dithering
- Passive matrix technology

#### 7.4.2.5.1 Color Phase Rotation

The Color Phase Rotation (CPR) can be used to correct the LCD output colorimetry in case of non pure white backlight.

The color phase rotation can be selected for passive matrix and active matrix panel. The logic is integrated after the LCD overlay manager or the palette while using the gamma correction and before the spatial/temporal dithering. The color phase rotation can be selected to correct the nonpure white backlight of the LCD module by using a programmable matrix to convert the 24-bit RGB pixel value into a new 24-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:255]. The color phase rotation is processed by the equation shown in [Figure 7-85](#).

**Figure 7-85. Color Phase Rotation Matrix**

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix}$$

dss-E076

[Figure 7-86](#) shows the color phase rotation macro-architecture.

**Figure 7-86. Color Phase Rotation Macro Architecture**

#### 7.4.2.5.1.1 Spatial/Temporal Dithering

The spatial/temporal dithering logic can be selected for passive matrix and active matrix panel. The dithering logic is integrated after the color phase rotation and before the TDM and passive matrix units. The spatial/temporal dithering logic can be selected to enhance the quality of the passive matrix and active matrix outputs. The dithering logic can process the pixels over a single frame, two frames, or four frames. In the case of a single frame, only spatial processing is applied. In the case of multiple frames, spatial and temporal processing is applied to the pixels.

- Passive Matrix Technology: The passive matrix display dithering logic path is used. The spatial/temporal dithering logic can be selected. When selected, the pixels are preprocessed by the spatial/temporal dithering logic before the passive matrix display dithering logic. The output format of the spatial/temporal dithering logic is RGB 12-bit (not configurable).

- Active Matrix Technology: The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the LCD panel. The spatial/temporal dithering algorithm is based on the (x,y) pixel position, the value of removed bits and the frame number. The picture quality is improved when enabling the spatial/temporal dithering logic. When spatial/temporal dithering is not enabled, the three MSBs of the pixel color components are output on the interface data bus if the interface data bus is smaller than the pixel format size. If the interface data bus is wider than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus or the LSB is filled with 0s.

#### 7.4.2.5.2 Passive Matrix Display Dithering Logic

- Passive matrix technology

After the graphics data are merged with the video data from the video layers depending on the transparency status, the result is sent to the color/grayscale space-/time-based dither generator. The monochrome data and each RGB color component are encoded on 4 bits, which are the 4 MSBs of the pixel-encoded component 8-bit value defined by the merge of the graphics data and the video data.

These 4-bit values are used to select on the 16 intensity levels. The gray/color intensity is controlled by turning individual pixels on and off at varying period rates, making the average time the pixel is off longer than the average time the pixel is on, thus producing more intense grays/colors. The dithering generator also uses the intensity of adjacent pixels in the calculation to give the screen image a smooth appearance. The proprietary dither algorithm is optimized to provide a range of intensity values that matches the visual perception of color/gray graduations.

- Active matrix technology

The passive matrix dithering logic is always bypassed in active displays.

---

**NOTE:** If the interface data bus is smaller than the pixel format size, dithering logic can be enabled. If the interface data bus is wider than the pixel format size, the dithering logic cannot be enabled and replication feature can be used.

---

#### 7.4.2.5.3 Passive Matrix Display Output FIFO

- Passive matrix technology

The display controller contains a 2-entry by 8-bit-wide output FIFO used to store pixel data before it is driven out to the LCD pins. Each time a modulated pixel value is output from the dither generator, it is placed into a serial shifter. The shifter can be configured to be 4 or 8 bits wide. Single-panel monochrome screens use either four or eight data lines; single-panel color screens use eight data pins.

- Active matrix technology

The output FIFO is bypassed in active matrix mode.

#### 7.4.2.5.4 Multiple Cycle Output Format

The pixels after the active matrix display processing are formatted on one or multiple cycles (from one to three cycles). The interface width can be 8-, 9-, 12-, or 16-bit. On three cycles, two pixels can concatenate and send to the panel. When the TDM is disabled, the display controller outputs the pixels using the conventional formats: Passive matrix display/active matrix display monochrome/color.

The following example shows an output configuration based on the interface width (8-bit) and the pixel format output (24-bit) (also see [Table 7-29](#)):

- The DSS.[DISPC\\_CONTROL](#)[24:23] TDMCYCLEFORMAT bit field is set to 0x2 (three cycles for one pixel).
- The DSS.[DISPC\\_DATA\\_CYCLEk](#) (k=0) register is set to 0x00000008 (8 bits from pixel 1 for the first cycle).
- The DSS.[DISPC\\_DATA\\_CYCLEk](#) (k=1) register is set to 0x00000008 (8 bits from pixel 1 for the second cycle).
- The DSS.[DISPC\\_DATA\\_CYCLEk](#) (k=2) register is set to 0x00000008 (8 bits from pixel 1 for the third cycle).

cycle).

**Table 7-29. 8-Bit Interface Configuration/24-Bit Mode**

|         | 24-Bit Mode |           |           |
|---------|-------------|-----------|-----------|
|         | 1st Cycle   | 2nd Cycle | 3rd Cycle |
| Data[7] | R0[7]       | G0[7]     | B0[7]     |
| Data[6] | R0[6]       | G0[6]     | B0[6]     |
| Data[5] | R0[5]       | G0[5]     | B0[5]     |
| Data[4] | R0[4]       | G0[4]     | B0[4]     |
| Data[3] | R0[3]       | G0[3]     | B0[3]     |
| Data[2] | R0[2]       | G0[2]     | B0[2]     |
| Data[1] | R0[1]       | G0[1]     | B0[1]     |
| Data[0] | R0[0]       | G0[0]     | B0[0]     |

#### 7.4.2.6 Video Line Buffer

The line buffer size is 1024 x 24-bit. There are six line buffers (1024 x 24-bit) that can be merged into three lines (2048 x 24-bit). [Table 7-30](#) lists the maximum width depending on the TAP configuration and the pixel format.

**Table 7-30. Maximum Width Allowed**

| Vertical Tap | Pixel Format | Maximum Width (Pixels) |
|--------------|--------------|------------------------|
| 3            | RGB16        | 2048                   |
|              | RGB24        |                        |
|              | YUV4:2:2     |                        |
| 5            | RGB16        | 1024                   |
|              | RGB24        |                        |
|              | YUV4:2:2     |                        |

#### 7.4.2.7 Synchronized Buffer Update

A synchronization mismatch between the frame buffer and the display refreshes, named tearing effect, can lead to images that appear to be stretched on the screen. To avoid this, a synchronization mechanism is needed between the display controller and the process that updates the buffer. An interrupt is generated when the display reaches a predefined line number. This PROGRAMMEDLINENUMBER interrupt is a level signal and stays active during the programmed line of the display.

#### 7.4.2.8 Rotation

In case of SDRAM buffer, the display controller accesses the encoded pixels in burst, always considering the consecutive data in memory. The rotation engine (VRFB) in the SDRAM scheduler (SDRC) is in charge of translating the addresses from virtual to physical SDRAM addresses (see [Chapter 10, Memory Subsystem](#)).

Rotation using the SMS-VRFB rotation engine is supported for BITMAP8, RGB12 (16-bit container), ARGB16, RGB16, RGB24 (using 32-bit container), ARGB32, RGBA32, and YUV4:2:2 (YUV2 and YUYV). The BITMAP1, BITMAP2, BITMAP4, and RGB24 (using 24-bit container) formats are not supported.

---

**NOTE:** For good performance in the L3 interconnect and for SDRAM efficiency, it is highly recommended to use the VRFB rotation engine when possible and not the display subsystem DMA engine to rotate the frame buffer.

---

A VID DMA optimization is available to optimize the memory traffic (DDR memory) when 90- and 270-degree rotation is required. This optimization consists of reconstructing the RGB16 and YUV line pixels using the cache capability of the DISPC scaler line buffers.

The pixel formats that can take advantage of the reduction in memory traffic are:

- YUV4:2:2
- RGB16 (no reduction is possible for RGB24 packed and unpacked formats)

The benefits of the video DMA optimization, when the feature is enabled, are:

- The L3 interconnect traffic is reduced by a factor of 2x (only for YUV4:2:2 pixel format)
- The DDR memory traffic is reduced by a factor of 2x (for YUV4:2:2 and RGB16 pixel formats)

For more information about the configuration settings for video DMA optimization, see [Section 7.5.3.4.5, Video DMA Optimization](#).

---

**NOTE:** The DMA optimization feature must be used only for YUV and RGB16 formats when 90- or 270-degree rotation is required. In all other configurations, the [DISPC\\_VIDn\\_ATTRIBUTES\[20\]](#) VIDDMAOPTIMIZATION bit must be kept at reset value (0x0).

---

#### 7.4.2.9 Multiple Buffer Support

Users update the base address of the buffer when the update of the working buffer has finished and is ready to be displayed. The register that contains the base address of the buffer is a shadow register that is read by the hardware at the next Vertical Front Porch (VFP).

#### 7.4.3 DS1 Protocol Engine Functionalities

---

**NOTE:** Copyright ©2005-2008 MIPI Alliance, Inc. All rights reserved. MIPI Alliance Member Confidential.

---

The DS1 protocol engine integrates DS1 interface to the display through the DS1 DS1\_PHY module, L4 interconnect interface and video interface from the display controller. The DS1 DS1\_PHY or complex I/O module is detailed in [Section 7.4.5](#). The DS1 transmitter (protocol engine + PHY) port can be connected to multiple displays using a single DS1 host port. The DS1 protocol engine controls the DS1 PLL control module detailed in [Section 7.4.4](#). The DS1 transmitter port can be used in video mode or/and command mode.

##### 7.4.3.1 DS1 Protocol Architecture

The DS1 protocol engine receives data from the video port and/or the L4 interconnect slave port, encapsulates them with the VC ID, generates the ECC and check-sum, and splits the data into byte stream to the DS1\_PHY to be sent using the low-speed (LS) or high-speed (HS) protocol. The DS1 protocol engine receives data and acknowledge from the display using the same DS1 link in case of bidirectional display. Multiple data streams can be interleaved to support multiple panels connected to the same host DS1 port. [Figure 7-87](#) details the DS1 protocol engine architecture.

Figure 7-87. DSI Protocol Engine

dss-166

**NOTE:** The order of the PHY pairs (clock and data lanes) is informative. Each PHY pair can be Clock or Data. The DSI complex I/O receives the configuration for pin order and the differential +/- in a pair from the settings in DSS.[DSI\\_COMPLEXIO\\_CFG1](#) register.

The DSI serial interface is a bidirectional differential serial interface with data/clock for the physical layer (configured in unidirectional link in case the display module is only unidirectional). The maximum DSI data transfer capacity is 900 Mbps per channel. The speed of the link can be software configured only when the DSI\_PHY is in stop state or in ULPS.

Figure 7-88 shows the DSI transmitter/receiver high-level data flow.

**Figure 7-88. DSI Transmitter/Receiver Data Flow**

dss-167

#### 7.4.3.2 Clock Requirements

The serial clock generated by the DSI host and sent to the display can be a continuous clock. The clock lane supports clock transmission even there is no data to send for displays that require continuous clock. It is software programmed through the DSS.[DSI\\_CLK\\_CTRL\[13\]](#) DDR\_CLK\_ALWAYS\_ON bit: This bit can be programmed only when the interface is disabled (that is, DSS.[DSI\\_CTRL\[0\]](#) IF\_EN bit set to 0).

The peripheral can use two different kinds of clocks. The first one is the DDR clock provided on the clock lane. The second clock is some transitions on the data lane 1 even if there is no valid data to send using low power mode.

The LP clock (TxClkEsc) frequency provided to the DSI complex I/O is in the range of 67% to 150% of the peripheral Low-Power (LP) clock frequency. It is generated internally by the DSI protocol engine module using the DSI functional clock. The DSI functional clock is divided by 1, 2, 3, up to 8191 using the value programmed in the DSS.[DSI\\_CLK\\_CTRL\[12:0\]](#) LP\_CLK\_DIVISOR bit field. The LP clock generated from DSI functional clock must be in the range of 20 MHz down to 32 KHz. The duty cycle must be 50/50 (tolerance of 45/55 for maximum value). LP clock frequency visible on the pads (DP xor DN) is half the frequency of TxClkEsc.

The DSS.[DSI\\_CLK\\_CTRL\[20\]](#) LP\_CLK\_ENABLE bit is used to enable or disable the clock. When disabled, the value of DSS.[DSI\\_CLK\\_CTRL\[12:0\]](#) LP\_CLK\_DIVISOR bit field is ignored and does not have to be programmed by software users.

#### 7.4.3.2.1 Timing Parameters for an LP to HS Transaction

Figure 7-89 shows the timing requirement when switching the data and clock lane state from LP to HS. Table 7-31 lists the LP to HS timing parameters.

**Figure 7-89. LP to HS Timing**

dss-325

**Table 7-31. LP to HS Timing Parameters**

| Timing                   | Description                                                                     | Registers/Associated Bit Fields                                                                                | Register Settings                | Timing Seen on the Line                                                                                                     |
|--------------------------|---------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| T <sub>LPX</sub>         | Length of any low-power state period                                            | DSI_PHY_REGISTER1[20:16]<br>REG_TLPXBY2<br><br>The value set in this bit field is half of the T <sub>LPX</sub> | CEIL (25 ns / DDR_Clock_Period)  | CEIL (2 * REG_TLPXBY2/4) * 4 * DDR_Clock_Period                                                                             |
| T <sub>CLK-PREPARE</sub> | Time to drive the CLK lane to LP-00 state, to prepare for HS clock transmission | DSI_PHY_REGISTER2[7:0]<br>REG_TCLKPREPARE                                                                      | CEIL (65 ns / DDR_Clock_Period)  | REG_TCLKPREPARE * DDR_Clock_Period + (~25 ns - +5 ns)                                                                       |
| T <sub>CLK-ZERO</sub>    | Time to drive the CLK lane to HS-0 state, before starting the clock             | DSI_PHY_REGISTER1[7:0]<br>REG_TCLKZERO                                                                         | CEIL (265 ns / DDR_Clock_Period) | {CEIL [(REG_TCLKZERO + 3)/4] * 4 + CEIL (REG_TCLKPREPARE/4) * 4 - REG_TCLKPREPARE + 2} * DDR_Clock_Period + (~0 ns - +5 ns) |

**Table 7-31. LP to HS Timing Parameters (continued)**

| Timing                         | Description                                                                                                    | Registers/Associated Bit Fields                                                 | Register Settings                                                                            | Timing Seen on the Line                                                                                                                                                                                          |

| $T_{CLK-PRE}$                  | Time that the HS clock must be driven before any associated data lane begins the transition from LP to HS mode | N/A                                                                             | N/A                                                                                          | $DDR\_CLK\_PRE - T_{LPX} - T_{CLK-PREPARE} - T_{CLK-ZERO}$                                                                                                                                                       |
| $T_{HS-PREPARE}$               | Time to drive the data lane to LP-00 state, to prepare for HS packet transmission                              | <a href="#">DSI_PHY_REGISTER0[31:24]</a><br><a href="#">REG_THSPREPARE</a>      | CEIL (70 ns / DDR_Clock_Period) + 2                                                          | $REG\_THSPREPARE * DDR\_Clock\_Period + (-26.5 \text{ ns} - +4 \text{ ns})$                                                                                                                                      |
| $T_{HS-ZERO} + T_{HS-PREPARE}$ | $T_{HS-ZERO}$ : Time to drive the data lane to HS-0 state before the synchronous sequence                      | <a href="#">DSI_PHY_REGISTER0[23:16]</a><br><a href="#">REG_THSPRPR_THSZERO</a> | CEIL (175 ns / DDR_Clock_Period) + 2                                                         | {CEIL [(N + 3)/4] * 4 + CEIL (M/4) * 4 + 3} * DDR_Clock_Period + (~ 29 ns - 0 ns).<br>Where<br>N = <a href="#">REG_THSPREPARE_THSZERO</a> - <a href="#">REG_THSPREPARE</a><br>M = <a href="#">REG_THSPREPARE</a> |
| $T_{DDR\_CLK\_PRE}$            | Time between the CLK lane request assertion and the data request assertion to switch the data lanes to HS      | <a href="#">DSI_CLK_TIMING[15:8]</a><br><a href="#">DDR_CLK_PRE</a>             | CEIL $[(T_{LPX} + T_{CLK-PREPARE} + T_{CLK-ZERO} + T_{CLK-PRE}) / T_{TXBYTECLKHS}]^{(1)(2)}$ |                                                                                                                                                                                                                  |
| $T_{ENTER\_HS\_MODE\_LATENCY}$ | <sup>(3)</sup> Time to enter data lane into HS mode                                                            | <a href="#">DSI_VM_TIMING7[31:16]</a><br><a href="#">ENTER_HS_MODE_LATENCY</a>  | CEIL $[(T_{LPX} + T_{HS-PREPARE} + T_{HS-ZERO}) / T_{TXBYTECLKHS}]^{(1)}$                    |                                                                                                                                                                                                                  |

(1) The timings seen on the line should be used to determine the register value.

(2) See the MIPI D-PHY specification for the  $T_{CLK-PRE}$  value.

(3)  $ENTER\_HS\_MODE\_LATENCY$  timing applies only to video mode. It does not need to be programmed in command mode.

In the example in [Table 7-32](#), the DDR clock = 400 MHz; TxByteClkHS = 100 MHz.

**Table 7-32. LP to HS Timing Parameters Example for 400-MHz DDR Clock**

| Timing                         | Registers/Associated Bit Fields                                                 | Default Register Settings (Programmed at Reset)                                                            | Timing Seen on the Line |
|--------------------------------|---------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|-------------------------|

(1) See the MIPI D-PHY specification for the  $T_{CLK-PRE}$  value.

(2) The register setting is calculated based on the values in the Timing Seen on the Line column.

#### 7.4.3.2.2 Timing Parameters for an HS to LP Transaction

Figure 7-90 shows the timing requirement when switching the state of the data and clock lanes from HS to LP. Table 7-33 lists the HS to LP timing parameters.

**Figure 7-90. HS to LP Timing**

**Table 7-33. HS to LP Timing Parameters**

| Timing                           | Description                                                                                                                                                                                                                         | Registers/Associated Bit Fields                             | Register Settings                                                                           | Timing Seen on the Line                                                                                          |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|---------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| $T_{HS-EOT}$                     | If EoT is enabled, a delay is added to EXIT_HS_MODE_LATENCY to send the EoT packet. The EoT period depends on the number of data lanes.                                                                                             | N/A                                                         | N/A                                                                                         | DIVROUNDUP (4, NB_DATA_LANES)<br><br>Thus:<br>One data lane = Four DDR clocks<br>Two data lanes = Two DDR clocks |
| $T_{HS-TRAIL}$                   | Time to drive flipped differential state after last payload data bit of an HS transmission burst                                                                                                                                    | <a href="#">DSI_PHY_REGISTER0[15:8]</a><br>REG_THSTRAIL     | CEIL (60 ns / DDR_Clock_Period) + 5                                                         | {CEIL [(REG_THSTRAIL + 3)/4] * 4 - 2.75} * DDR_Clock_Period + (~ 0 ns - 5 ns)                                    |
| $T_{HS-EXIT}$                    | Time to drive data lane to LP-11 state, after HS burst                                                                                                                                                                              | <a href="#">DSI_PHY_REGISTER0[7:0]</a><br>REG_THSEXIT       | CEIL (145 ns / DDR_Clock_Period)                                                            | [CEIL (REG_THSEXIT/4 * 4) * DDR_Clock_Period - (~ 3 ns - 45 ns)]                                                 |
| $T_{CLK-POST}$                   | Time that the transmitter must continue sending HS clock after the last associated data lane has transitioned to LP mode                                                                                                            | N/A                                                         | N/A                                                                                         | DDR_CLK_POST - $T_{HS-EOT}^{(1)} - T_{HS-TRAIL}$                                                                 |
| $T_{CLK-TRAIL}$                  | Time to drive HS differential state after last payload clock bit of a HS transmission burst                                                                                                                                         | <a href="#">DSI_PHY_REGISTER1[15:8]</a><br>REG_TCLKTRAIL    | CEIL (60 ns / DDR_Clock_Period) + 2                                                         | {CEIL [(REG_TCLKTRAIL + 3)/4] * 4 - 1.5} * DDR_Clock_Period + (~ 0 ns - 5 ns)                                    |
| $T_{DDR_CLK_POST}$               | Time between the data lane request deassertion and the CLK request deassertion to switch the data lanes into LP mode. The DDR_CLK_POST value must follow the rule: $T_{DDR_CLK_POST} \geq T_{HS-TRAIL} + T_{HS-EOT} + T_{CLK-POST}$ | <a href="#">DSI_CLK_TIMING[7:0]</a><br>DDR_CLK_POST         | CEIL [( $T_{HS-TRAIL} + T_{HS-EOT}^{(1)}$ + $T_{CLK-POST}$ ) / $T_{TXBYTECLKHS}^{(2)(3)}$ ] |                                                                                                                  |
| $T_{EXIT_HS_MODE_LATENCY}^{(4)}$ | Time to exit HS mode                                                                                                                                                                                                                | <a href="#">DSI_VMTIMING7[15:0]</a><br>EXIT_HS_MODE_LATENCY | CEIL [( $T_{HS-TRAIL} + T_{HS-EXIT} + T_{HS-EOT}^{(1)}$ ) / $T_{TXBYTECLKHS}^{(2)}$ ]       |                                                                                                                  |

(1) If  $T_{HS-EOT}$  is enabled

(2) The timings seen on the line should be used to determine the register value.

(3) See the MIPI D-PHY specification for the  $T_{CLK-POST}$  value.

(4) EXIT\_HS\_MODE\_LATENCY timing applies only to video mode. It does not need to be programmed in command mode.

In the example in [Table 7-34](#), the DDR clock = 400 MHz; TxByteClkHS = 100 MHz; two data lanes.

**Table 7-34. HS to LP Timing Parameters Example for 400-MHz DDR Clock and Two Data Lanes**

| Timing       | Registers/Associated Bit Fields | Default Register Settings (Programmed at Reset) | Timing Seen on the Line ( $T_{HS-EOT}$ Enabled) | Timing Seen on the Line ( $T_{HS-EOT}$ Disabled) |
|--------------|---------------------------------|-------------------------------------------------|-------------------------------------------------|--------------------------------------------------|
| $T_{HS-EOT}$ | N/A                             | N/A                                             | 5 ns                                            | N/A                                              |

<sup>(1)</sup> See the MIPI D-PHY specification.

<sup>(2)</sup> The register setting is calculated based on the values in the Timing Seen on the Line ( $T_{HS-EOT}$  Enabled) column.

#### 7.4.3.2.3 Extra LP Transitions

Some DSI receivers require extra clock cycles in LP mode to process the data. The DSI protocol engine can be programmed to send automatically one NULL long packet. It applies only when no more data are ready to be sent from the internal FIFO to the peripheral on the last low speed transfer. The same value is used for all the VCs sending packets in low speed mode.

The size of the payload is defined by the DSS.DSI\_CLK\_CTRL[17:16] LP\_CLK\_NULL\_PACKET\_SIZE bit field. The header value depends on the VC ID and the size of the payload as detailed in [Table 7-35](#) and [Table 7-36](#).

**Table 7-35. Extra NULL Packet Header**

| Virtual Channel ID | Payload size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE) | Header (1st Byte) | Header (2nd Byte): WC LSB | Header (3rd Byte): WC MSB | Header (ECC) |
|--------------------|------------------------------------------------------------|-------------------|---------------------------|---------------------------|--------------|
| 0x0                | 0                                                          | 0x9               | 0x0                       | 0x0                       | 0x9          |

| 0x1                | 0                                                          | 0x49              | 0x0                       | 0x0                       | 0x1F         |
|                    | 1                                                          |                   | 0x1                       |                           | 0x05         |
|                    | 2                                                          |                   | 0x2                       |                           | 0x39         |
|                    | 3                                                          |                   | 0x3                       |                           | 0x23         |
| 0x2                | 0                                                          | 0x89              | 0x0                       | 0x0                       | 0x10         |
|                    | 1                                                          |                   | 0x1                       |                           | 0x0A         |
|                    | 2                                                          |                   | 0x2                       |                           | 0x36         |
|                    | 3                                                          |                   | 0x3                       |                           | 0x2C         |
| 0x3                | 0                                                          | 0xC9              | 0x0                       | 0x0                       | 0x06         |
|                    | 1                                                          |                   | 0x1                       |                           | 0x1C         |
|                    | 2                                                          |                   | 0x2                       |                           | 0x20         |
|                    | 3                                                          |                   | 0x3                       |                           | 0x3A         |

**Table 7-36. Extra NULL Packet Payload**

| Payload size<br>(DSI_CLK_CTRL[17:16]<br>LP_CLK_NULL_PACKET_SIZE) | Payload (1st byte) | Payload (2nd byte) | Payload (3rd byte) | Payload (CRC) LSB | Payload (CRC) MSB |
|------------------------------------------------------------------|--------------------|--------------------|--------------------|-------------------|-------------------|
| 0                                                                | NA                 | NA                 | NA                 | 0xFF              | 0xFF              |
| 1                                                                | 0                  | NA                 | NA                 | 0x87              | 0x0F              |
| 2                                                                | 0                  | 0                  | NA                 | 0xB8              | 0xF0              |
| 3                                                                | 0                  | 0                  | 0                  | 0x33              | 0x39              |

**NOTE:**

- In [Table 7-35](#) and [Table 7-36](#), both ECC and checksum are enabled.
- NA means not available.

**7.4.3.3 DSI Transfer Modes**

There are two transfer modes supported by the DSI module:

- Video mode (VM): Pixels are received from the video port, there are some real time constraints (pixels must be sent at the pixel frequency required by the display module) for sending the data to the display;
- Command mode (CM): Pixels can be received from the video port or from the L4 interconnect, there are no real time constraints except that TE must be avoided by starting the transfer at the right time during scan of the display and should be fast enough.

**7.4.3.3.1 Video Mode**

The video mode refers to the MIPI DPI 1.0 standard. The sync events and pixels must be sent according to the display mode timings. Data are received from the video port. The display controller is in charge of fetching the data from the system memory and providing the data to the DSI protocol engine using the video port. The short packets used for the sync event are using precalculated 32-bit values. The long packets are constructed using the header defined in [DSS.DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#) registers.

**7.4.3.3.2 Command Mode**

The command mode refers to the MIPI DCS standard. The commands, parameters and pixels are sent to the display module with limited real time constraints (as defined in [Section 7.4.3.3.1](#)). The pixels can be provided on the video port by the display controller or on the L4 interconnect port.

---

**NOTE:** In DSI command mode, the display controller must be configured in stall mode by setting the [DSS.DISPC\\_CONTROL\[11\]](#) STALLMODE bit to 1.

---

The [DSS.DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#) registers are used for the header of long packets, the [DSS.DSI\\_VCn\\_SHORT\\_PACKET\\_HEADER](#) registers are used for the short packets.

The error correction code (ECC) can be provided while writing the ECC value directly into the [DSS.DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#) and [DSS.DSI\\_VCn\\_SHORT\\_PACKET\\_HEADER](#) registers. The [DSS.DSI\\_VCn\\_CTRL\[8\]](#) ECC\_TX\_EN bit indicates if the ECC value should be calculated or if the value written in the register should be used instead for command and video modes. In case of synchronization short packets for video mode, since the hardware generates the short packets without using [DSS.DSI\\_VCn\\_SHORT\\_PACKET\\_HEADER](#) registers. If the [DSS.DSI\\_VCn\\_CTRL\[8\]](#) ECC\_TX\_EN bit is set to 1, the ECC is calculated; otherwise, the value zero is used. The feature is used to generate incorrect ECC for debug purpose and to ease the check for the link and peripheral error detection and correction.

For the payload, the DSS.[DSI\\_VCn\\_LONG\\_PACKET\\_PAYLOAD](#) registers are used. Each 32-bit PAYLOAD data is written into the DSS.[DSI\\_VCn\\_LONG\\_PACKET\\_PAYLOAD](#) register from the MPU subsystem or system DMA. It is buffered to be able to send packets with higher rate than the L4 interconnect frequency can provide. The word count defined in the DSS.[DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#) registers is used to determine the number of bytes to be sent using the DSS.[DSI\\_VCn\\_LONG\\_PACKET\\_PAYLOAD](#) registers. The write into the DSS.[DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#) registers is required before accessing the DSS.[DSI\\_VCn\\_LONG\\_PACKET\\_PAYLOAD](#) register. The hardware must be able to extract the length of the payload and be able to discard extra data sent using the DSS.[DSI\\_VCn\\_LONG\\_PACKET\\_PAYLOAD](#) register. The hardware takes into account the write into the DSS.[DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#) register only if the VC is enabled otherwise the write is ignored by hardware.

In the case of pixels received on the video port, only the DSS.[DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#) register is used. The video port pixels are used for the payload. When the pixel data is coming from the display controller video port, the DSI protocol can add a DCS command byte between the packet header and pixel data by setting the DSS.[DSI\\_CTRL\[24\]](#) DCS\_CMD\_ENABLE bit to 0x1. The value will be either 0x2c (write\_memory\_start) by setting the DSS.[DSI\\_CTRL\[25\]](#) DCS\_CMD\_CODE bit to 0x1, or 0x3c (write\_memory\_continue) by setting the DSS.[DSI\\_CTRL\[25\]](#) DCS\_CMD\_CODE bit to 0x0.

When transmitting RGB 16-BPP data, the DSS.[DSI\\_CTRL\[26\]](#) RGB565\_ORDER bit must be set to 0x1 to maintain the pixel byte order as in video mode .

A 2-line ping-pong buffer is implemented to allow the DSI protocol engine to store incoming pixels from the display controller through the video port while sending the DSI formatted frame to the DSI\_PHY. The ping-pong buffer is supported in command mode, provided the size of the packet defined in the header register is less than the size of each line buffer (768 \*32 bits). If the size of the packet is greater than the size of the line buffer, the ping-pong mechanism cannot be used (both lines are used as a single line).

The ping-pong buffer status can be checked by the [DSI\\_VCn\\_CTRL\[14\]](#) PP\_BUSY bit.

- When PP\_BUSY equals 1, the ping-pong buffer is active and the line buffers are not ready to receive data; therefore, the user cannot update a new header.
- When PP\_BUSY equals 0, at least one line buffer is empty; therefore, the user can update a new header. PP-BUSY is then set to 0x1. If both line buffers are empty, the user can write two headers, one following the other. PP\_BUSY remains at 0x0 after the first header is written, and is set to 0x1 after second header is written.

An IRQ is available to allow software to update header on events. The IRQ is enabled by setting the [DSI\\_VCn\\_IRQENABLE\[8\]](#) PP\_BUSY\_CHANGE\_IRQ bit to 0x1, and its status is accessible on the [DSI\\_VCn\\_IRQSTATUS\[8\]](#) PP\_BUSY\_CHANGE\_IRQ bit.

#### 7.4.3.3.3 Video + Command Modes

The two modes can be interlaced to send two DSI streams to two types of panels: Video or command types. The number of concurrent video stream is limited to a single one. The number of concurrent command mode streams is limited to 4 when there is no video stream and 3 otherwise. In case there is one DSI stream using video mode, the command mode pixels must be provided only on the L4 interconnect.

#### 7.4.3.3.4 Burst Modes

- Frequency-burst mode The frequency-burst mode is used to reduce the high-speed (HS) period by increasing the clock frequency on the DSI link. It allows in some case, the power consumption reduction of the link. The non-HS period used typically to drive the main panel can be used to send data to the secondary panel or to allow feedback (acknowledge) from the primary and secondary panels. The DSI protocol engine needs to buffer a full line before sending the HS packets for the line. A double buffering mechanism is required to be able to send a line while the following one is being received on the video port.
- Transparent-burst mode The transparent-burst mode is used by increasing the pixel clock frequency generated by the display controller with in addition an increase of the horizontal blanking period.

#### 7.4.3.3.5 Interleaving Mode

Video mode can output command mode packets, which are provided to DSI through the L4 interconnect, during the blanking periods of the video stream sequence on the PPI link. These command mode packets can be programmed as high-speed packets or low-power packets.

During a video stream sequence on the PPI link, four types of gap exist:

- BLLP gap: Blanking period during VSA, VBP, and VFP lines
- HSA gap: Blanking period during VACT lines; always between HS and HE short packet
- HBP gap: Blanking period during VACT lines; always between HS/HE short packet and data pixel long packet
- HFP gap: Blanking period during VACT lines; always between data pixel long packet and the end of the current VACT line

To perform interleaving in a particular gap, video mode must be set to go into low-power state during the blanking gap. Each type of gap has separate configurable register bits that determine whether a blanking long packet will be sent or the link will go into low-power state during the gap on the PPI link. If low-power state is set during a gap, the DSI module performs interleaving during that period.

Two set of registers are available for:

- High-speed interleaving (when high-speed command mode packets must be sent during a video stream on the PPI link)
- Low-power interleaving (when low-power command mode packets must be sent during a video stream on the PPI link)

##### 7.4.3.3.5.1 HS Command Mode Interleaving Programming Model

Figure 7-91 shows the various HS mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of TxByteClkHS clock cycles used for interleaving in HS command mode packets.

- The BL\_HS\_INTERLEAVING[31:16] [DSI\\_VM\\_TIMING6](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during a BLLP gap.
- The HBP\_HS\_INTERLEAVING[7:0] [DSI\\_VM\\_TIMING4](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HBP gap.
- The HFP\_HS\_INTERLEAVING[15:8] [DSI\\_VM\\_TIMING4](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HFP gap.
- The HSA\_HS\_INTERLEAVING[23:16] [DSI\\_VM\\_TIMING4](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HSA gap.

These programmable values must be programmed to satisfy the timings for the clock and data lane to enter and exit HS mode latency. According to the scenario, different equations must be considered when calculating the register values.

**Figure 7-91. HS Command Mode Interleaving**

dss-327

**NOTE:** For calculations and equations, the following abbreviations are used: EXIT\_CLK\_HS\_MODE represents the exit HS mode latency for the clock lane. There is no dedicated register for this value but the programmer must know this value for further calculations.

$$\text{EXIT_CLK_HS_MODE} = T_{\text{CLK-TRAIL}} + T_{\text{H-S-EXIT}}$$

For the following equations, BLANKING\_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The HS\_INTERLEAVING period represents the maximal period HS command mode packets. Its value is set in the BL\_HS\_INTERLEAVING, HSA\_HS\_INTERLEAVING, HBP\_HS\_INTERLEAVING, or HFP\_HS\_INTERLEAVING registers, depending on the blanking type.

In each scenario, two calculations are present, depending on the value of ddr\_clk\_always\_on.

- $\text{ddr\_clk\_always\_on} = 1$ : Clock lane is always active.
- $\text{ddr\_clk\_always\_on} = 0$ : Clock lane is activated only when there are HS packets to be sent on the PPI link.
- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.
  - $\text{ddr\_clk\_always\_on} = 1$
$$\text{HS\_INTERLEAVING} = \text{BLANKING\_PERIOD} - (\text{EXIT\_HS\_MODE\_LATENCY} + \max\{\text{ENTER\_HS\_MODE\_LATENCY}, 2\} + 1)$$
  - $\text{ddr\_clk\_always\_on} = 0$
$$\text{HS\_INTER1} = \text{BLANKING\_PERIOD} - (\text{EXIT\_HS\_MODE\_LATENCY} + \max\{$$

- ```
ENTER_HS_MODE_LATENCY, 2} + 1)
HS_INTER2 = BLANKING_PERIOD - (DDR_CLK_POST + EXIT_CLK_HS_MODE +
DDR_CLK_PRE+ ENTER_HS_MODE_LATENCY + 1)
HS_INTERLEAVING = min{ HS_INTER1, HS_INTER2}

• Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LP state.
– ddr_clk_always_on = 1
    HS_INTERLEAVING = BLANKING_PERIOD - (EXIT_HS_MODE_LATENCY + 3)
– ddr_clk_always_on = 0
    HS_INTER1 = BLANKING_PERIOD - (EXIT_HS_MODE_LATENCY + 3)
    HS_INTER1 = BLANKING_PERIOD - (DDR_CLK_POST + EXIT_CLK_HS_MODE + 3)
    HS_INTERLEAVING = min{ HS_INTER1, HS_INTER2}
• Scenario 3: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
– ddr_clk_always_on = 1
    HS_INTERLEAVING = BLANKING_PERIOD - (ENTER_HS_MODE_LATENCY +
    EXIT_HS_MODE_LATENCY + max{ ENTER_HS_MODE_LATENCY, 2} + 1)
– ddr_clk_always_on = 0
    HS_INTER1 = BLANKING_PERIOD - (DDR_CLK_PRE + ENTER_HS_MODE_LATENCY +
    EXIT_HS_MODE_LATENCY + max{ ENTER_HS_MODE_LATENCY, 2} + 1)
    HS_INTER2 = BLANKING_PERIOD - (DDR_CLK_PRE + ENTER_HS_MODE_LATENCY +
    DDR_CLK_POST + EXIT_CLK_HS_MODE + DDR_CLK_PRE+ ENTER_HS_MODE_LATENCY +
    1)
    HS_INTERLEAVING = min{ HS_INTER1, HS_INTER2}
• Scenario 4: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
– ddr_clk_always_on = 1
    HS_INTERLEAVING = BLANKING_PERIOD - (ENTER_HS_MODE_LATENCY +
    EXIT_HS_MODE_LATENCY + 3)
– ddr_clk_always_on = 0
    HS_INTER1 = BLANKING_PERIOD - (DDR_CLK_PRE+ ENTER_HS_MODE_LATENCY +
    EXIT_HS_MODE_LATENCY + 3)
    HS_INTER2 = BLANKING_PERIOD - (DDR_CLK_PRE+ ENTER_HS_MODE_LATENCY +
    DDR_CLK_POST + EXIT_CLK_HS_MODE + 1)
    HS_INTERLEAVING = min{ HS_INTER1, HS_INTER2}
```

7.4.3.3.5.2 LP Command Mode Interleaving Programming Model

Figure 7-92 shows the various LP mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of bytes of LP command mode packets that can be sent during a blanking period.

- BL_LP_INTERLEAVING bit field [DSI_VM_TIMING6\[15:0\]](#) defines the number of bytes of LP command mode packets that can be sent during a BLLP gap.
- HBP_LP_INTERLEAVING bit field [DSI_VM_TIMING5\[7:0\]](#) defines the number of bytes of LP command mode packets that can be sent during a HBP gap.
- HFP_LP_INTERLEAVING bit field [DSI_VM_TIMING5\[15:8\]](#) defines the number of bytes of LP command mode packets that can be sent during a HFP gap.
- HSA_LP_INTERLEAVING bit field [DSI_VM_TIMING5\[23:16\]](#) defines the number of bytes of LP command mode packets that can be sent during a HSA gap.

These programmable values must be programmed to satisfy the timings for clock and data lane enter and exit LP mode latency. Clock lane timings do not affect LP command mode interleaving, because the clock lane can be controlled separately, compared with the data lane high-speed and low-power mutually exclusive control. Clock lanes can be in high-speed mode while the data lanes are in high-speed data transfer mode, low-power data transfer mode, or in low-power state.

According to this scenario, different equations must be considered for calculating register values.

Figure 7-92. LP Command Mode Interleaving

dss-328

For the following equations, BLANKING_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The LP_INTERLEAVING period represents the maximal period in LP command mode packets. Its value is set in the BL_LP_INTERLEAVING, HSA_LP_INTERLEAVING, HBP_LP_INTERLEAVING, or HFP_LP_INTERLEAVING registers, depending on the blanking type.

ALLOWED_HSBYTE_CLOCKS_FOR_LP represents the number of TxByteClkHS clock cycles during which LP interleaving can appear.

To calculate the LP_INTERLEAVING value:

1. Calculate how many TxByteClkHS clock cycles can be reserved for LP interleaving during the appropriate blanking video mode gap.
2. Calculate the LP_INTERLEAVING value according to the results of Step 1.

Step 1:

- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.

- $\text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + \max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$
- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LP state.
 $\text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + 1)$
 - Scenario 3: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
 $\text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} = \text{BLANKING_PERIOD} - (\max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$
 - Scenario 4: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
 $\text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} = \text{BLANKING_PERIOD} - 1$

After finishing Step 1, the time period available for LP interleaving is known:

$$T_{lp_available} = \text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} * T_{TxByteClkHS}$$

Step 2:

The resulting value must be programmed in the appropriate video mode register for LP interleaving.

$$\text{LP_INTERLEAVING} < \left[\frac{T_{lp_available} - 8*T_{hsbyte_clk} - 5*T_{dsif_clk} - 26}{T_{txclkesc}} \right]_{16}$$

dss-E124

$T_{TxByteClkHS}$: Period of HS byte clock of DSI_PHY module

T_{dsif_clk} : Period of DSI functional clock

$T_{txclkesc}$: Period of LP transmit escape clock

7.4.3.4 Power Management

The DSI protocol engine implements an handshake protocol on its L4 interconnect port with the PRCM. The DSI protocol engine provides a clock gating signal CIO_CLK_ICG to gate the L3 interface clock (L3_ICLK) provided by the PRCM to the DSI complex I/O. It allows reduction of the power consumption of the DSI complex I/O while the DSI link is not in used. To gate the L3_ICLK clock at DSI complex I/O level, set the DSS.[DSI_CLK_CTRL\[14\]](#) CIO_CLK_ICG bit to 1.

7.4.3.5 Serial Configuration Port (SCP) Interface

The SCP interface is used to transfer register values from the DSI protocol engine to the DSI PLL Control module and to the DSI complex I/O. It spends several cycles to serialize the data to be sent. Software users must consider the delay in processing the transfer of the data from/to the slave port to/from the module.

7.4.3.5.1 Shadowing Register

The two first SCP registers for the DSI complex I/O address map must be implemented as shadow registers. The shadowing mechanism is enabled/disabled using the DSS.[DSI_COMPLEXIO_CFG1\[31\]](#) SHADOWING bit:

- When setting the DSS.[DSI_COMPLEXIO_CFG1\[31\]](#) SHADOWING bit to 1, the transfer of the values from the two first L4 interconnect port registers into the two first registers of the DSI complex I/O ([DSS.DSI_PHY_REGISTER0](#) and [DSS.DSI_PHY_REGISTER1](#)) is done only when the DISPC_UPDATE_SYNC signal from the display controller is active and the DSS.[DSI_COMPLEXIO_CFG1\[30\]](#) GOBIT is set to 1. If there is no pending update for the two registers, when the DISPC_UPDATE_SYNC signal is asserted, the DSS.[DSI_COMPLEXIO_CFG1\[30\]](#) GObit is reset by hardware and there is no SCP transfer.
 - If there is only one register to update, only the corresponding new value is transferred. The second register in the DSI complex I/O is not updated. When the transfer is completed, the

DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is reset by hardware.

- If the two registers need to be updated, the order of the transfer is first the register with lower address and then the second one. When the transfers are completed, the DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is reset by hardware.
- When there is an on-going transfer (read or write) to any SCP register, the transfer must complete before starting the update of shadowing registers.
- When unsetting the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 0, if the transfer into the two first DSI complex I/O registers has already started, it should be finished.

NOTE: When reading the shadow registers, the local value stored in the DSI protocol engine is returned if the update is pending; otherwise, the values stored in the DSI complex I/O are returned.

7.4.3.5.2 Busy Signal

The signal SCPBusy indicates that there is still some activity using the SCPClk provided by the PRCM. The SCPClk clock is the DSS_L3_ICLK clock.

7.4.3.6 Power Control

The DSI protocol engine can control and send power commands for both DSI complex I/O and DSI PLL controller modules.

7.4.3.6.1 Complex I/O Power Control Commands

The DSI complex I/O can be set into three modes:

- OFF: In this power state, the complete DSI_PHY circuit is powered down. The internal LDO is OFF.
- ON: In this power state, the complete DSI_PHY circuit is powered on and functional.
- ULPS: In this power state, the ULPS exit detection circuit power switch is ON for the lanes which are in receive ULPS mode. For the lanes which are in transmit ULPS mode, the circuitry for weak pull-down is ON. The ultralow-power state should only be used when all the three lanes are in ULPS (transmit or receive).

7.4.3.6.1.2 Complex I/O Power FSM

Figure 7-93 describes the power control FSM to control the power state of the complex I/O.

Figure 7-93. Complex I/O Power FSM

dss-169

The PwrCmdOff, PwrCmdUlP and PwrCmdOn commands control the state transition of the DSI complex I/O. Software users must set the DSS.[DSI_COMPLEXIO_CFG1\[28:27\]](#) PWR_CMD bit field to ask for a state change. The allowed transitions are: OFF - ON and ON - ULP and ULP - OFF. The DSS.[DSI_COMPLEXIO_CFG1\[26:25\]](#) PWR_STATUS bit field gives a status on the current state of the DSI complex I/O.

CAUTION

- In automatic mode, software must ensure that the DSI complex I/O in the ON mode (that is, ON command already sent) before sending requests to the complex I/O.
- In a command request to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI complex I/O).
- To change state to ULP state, users must ensure that all the three ULPSActiveNot signals are low. The ULPSActiveNot_ALL0_IRQ interrupt can be used by software users to determine the state of the ULPSActiveNot signals. The change from ULP to ON state is required before starting the ULP status exit sequence (see [Section 7.4.3.7.1](#) for details).

7.4.3.6.2 DSI PLL Power Control Commands

The DSI PLL controller module can be set into four modes:

- OFF: The DSI PLL and HSDIVIDER are OFF.
- ON ALL: Both DSI PLL and HSDIVIDER are ON. The HS_CLK clock is provided to the DSI complex I/O and the second clock output is provided to the HSDIVIDER.
- ON HSCLK: The DSI PLL is ON. The HSDIVIDER is OFF. The HS_CLK clock is provided to the DSI complex I/O but the second clock output is not provided to the HSDIVIDER.
- ON DIV: Both DSI PLL and HSDIVIDER are ON. The HS_CLK clock is not provided to the DSI complex I/O but the second clock output is provided to the HSDIVIDER.

7.4.3.6.2.1 DSI-PLL Power FSM

Figure 7-94 shows the DSI PLL power FSM.

Figure 7-94. DSI PLL Power FSM

- 1 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x0 (STATE_OFF)
- 2 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x1 (STATE_ON_HSCLK)
- 3 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x2 (STATE_ON_ALL)
- 4 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x3 (STATE_ON_DIV)

dss-170

The commands PLLPwrCmdOff, PLLPwrCmdOnAll, PLLPwrCmdOnDIV and PLLPwrCmdOnHSCLK controls the state transition of the DSI PLL control module. Software users must set the DSS.DSI_CLK_CTRL[31:30] PLL_PWR_CMD bit field to ask for a state change. The DSS.DSI_CLK_CTRL[29:28] PLL_PWR_STATUS bit field gives a status on the current state of the DSI PLL controller.

NOTE: In a command requests to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI PLL Control module).

All the DSI PLL power is controlled by the DSI protocol engine except the LDO power of the PLL and HSDIVIDER that can be controlled by the DSI PLL controller module. Indeed, the HSDIVIDER and PLL SYSRESET signals can be forced by the DSI PLL controller module by setting DSS.DSI_PLL_CONTROL[4] DSI_HSDIV_SYSRESET and DSS.DSI_PLL_CONTROL[3] DSI_PLL_SYSRESET bits, respectively. By setting these bits to 1, the SYSRESET signal is forced active (module is forced to reset state). When these bits are set to 0 (reset value), the SYSRESET signals are controlled by the DSI PLL power FSM.

7.4.3.6.2.1.1 DSI-PLL HS Clock Signals

The DSIStopClk signal is provided to the DSI PLL control module. It indicates when the DSI Protocol engine does not need to use the high-speed transfer mode (HS mode) and PLL HS output (HS_CLK clock) can be stopped. The following conditions must also be met when DISPC_UPDATE_SYNC may be generated by the display controller, as that may also result in the PLL HS output being stopped.

When the interface is disabled (that is, DSS.[DSI_CTRL\[0\]](#) IF_EN bit set to 0), the signal DSIStopClk is asserted.

The assertion of the DSIStopClk depends on the following conditions:

- Clock lane TxRequestHS is deasserted (the DDR clock on the clock lane is not required anymore). The get TxRequestHS deassertion, all of the following conditions are required:
 - The DSS.[DSI_CLK_CTRL\[13\]](#) DDR_CLK_ALWAYS_ON bit must be reset to 0 and no HS data transfer should be ongoing or already scheduled.
 - No VC active in video mode. No VC using the video mode is enabled; if the VC is enabled, the mode is command mode only (that is, DSS.[DSI_VCn_CTRL\[0\]](#) VC_EN bit set to 1 and DSS.[DSI_VCn_CTRL\[4\]](#) MODE bit set to 0).
 - No command mode requiring high-speed transfer (one or more VCs using command mode can be active)
 - Or DSS.[DSI_CTRL\[0\]](#) IF_EN bit reset to 0 (if all previous conditions are not required)

The deassertion of the DSIStopClk depends on one of the following conditions (the DSI interface is enabled by setting the DSS.[DSI_CTRL\[0\]](#) IF_EN bit to 1):

- Clock lane TxRequestHS must be asserted (the DDR clock on the clock lane is required anymore).
- One video mode VC active
- At least one VC in command mode requiring high-speed transfer
- The DSS.[DSI_CLK_CTRL\[13\]](#) DDR_CLK_ALWAYS_ON bit is set to 1 by software users (the DSS.[DSI_CTRL\[0\]](#) IF_EN bit must be reset to 0 to update the DDR_CLK_ALWAYS_ON bit value)

Automatic assertion/deassertion is enabled by using the DSS.[DSI_CLK_CTRL\[18\]](#) HS_AUTO_STOP_ENABLE bit.

Manual mode can be used by setting/resetting the DSS.[DSI_CLK_CTRL\[19\]](#) HS_MANUAL_STOP_CTRL bit to assert/deassert the DSIStopClk signal.

7.4.3.6.2.1.2 DSI-PLL HS Clock FSM

Figure 7-95 shows the DSI PLL HS clock FSM.

Figure 7-95. DSI PLL HS Clock FSM

dss-171

When DSIStopClk is used there is a latency through other modules (DSI PLL controller and DSI_PHY)

before TxByteClkHS is stopped. This latency must be accounted for to prevent any issue when DSIStopClk is deasserted soon after being asserted. This is done using a hardware timer programmed using the DSS.[DSI_STOPCLK_TIMING\[7:0\]](#) DSIStopclk_Latency bit field. This timer is programmed in number of periods of the DSIS Protocol functional clock (DSI_FCLK). At reset value, the timer is programmed with 0x80 (128) value.

CAUTION

The programmed value in the DSS.[DSI_STOPCLK_TIMING\[7:0\]](#) DSIStopclk_Latency bit field must be greater than ((3 x L3_ICLK period) + (5 x CLKIN4DDR period))/(DSI_FCLK period).

7.4.3.7 Timers

NOTE: Among the timers described in this section, only the HS TX, LP RX and turnRequests timers generates interrupts immediately when the timer value is null. For ForceTxStopMode timer, it ends counting instantly and ForceTxStopMode is not asserted.

7.4.3.7.1 Twakeup Timer

The T_{WakeUp} timer is not implemented in the DSIS protocol engine. The software must use a general-purpose (GP) timer to handle this. This timer is used for existing ULP status mode for the active lanes (clock and/or data lanes). The sequence to exit ULP state is:

1. Change the state of TxULPSExit for each lane to ACTIVE.
2. Wait for the interrupt indicating that all lanes with TxULPSExit active have acknowledged by asserting ULPSActiveNot. This is done by reading the DSS.[DSI_COMPLEXIO_IRQSTATUS](#) ULPSACTIVENOT_ALLi_IRQ bit fields ($i = 0, 1$).
3. Start the application wake-up timer (GP timer).
4. Wait for the time-out.
5. Change the TxUlpsClk signals to INACTIVE state for the clock lane and/or TxRequestEsc INACTIVE state for the data lane(s).

NOTE: The minimum time for the wake-up period is 1 ms.

To enter ULPS mode for clock lane, TxUlpsClk state must be changed to active state. To enter ULPS mode for data lane, TxRequestEsc state must be changed to active state (TxUlpsEsc as well if it is not already in active state).

7.4.3.7.2 ForceTxStopMode FSM

The signal ForceTxStopMode is used at initialization time (DSI complex I/O). [Figure 7-96](#) describes the ForceTxStopMode FSM to assert/deassert ForceTxStopMode signal.

Figure 7-96. ForceTxStopMode FSM

dss-172

The DSI protocol engine asserts ForceTxStopMode by setting the DSS.[DSI_TIMING1\[15\]](#) FORCE_TX_STOP_MODE_IO bit to 1. Asserting the FORCE_TX_STOP_MODE_IO bit allows to initialize the lanes. The lanes are in the Stop State when ForceTxStopMode signal is high.

No data can be sent before the ForceTxStopMode signal is deasserted. The deassertion time is defined by the STOP_STATE_COUNTER_IO, Stop_State_x4_IO, Stop_State_x16_IO field [DSI_TIMING1\[15:0\]](#). The FORCE_TX_STOP_MODE_IO bit is reset by hardware when the time is reached.

This bit can be reset by software.

The calculation of the number of DSI_FCLK cycles assertion period is defined by:

Total period in DSI_FCLK cycles = [DSI_TIMING1\[12:0\]](#) STOP_STATE_COUNTER_IO x (([DSI_TIMING1\[14\]](#) STOP_STATE_X16_IO x 15) + 1) x (([DSI_TIMING1\[13\]](#) STOP_STATE_X4_IO x 3) + 1)

7.4.3.7.3 TurnRequest FSM

The signal TurnRequest is used to request turnaround. It is only valid for the data lane #1 since the other data lanes cannot be used in the reverse direction to receive data from the DSI receiver. [Figure 7-97](#) describes the TurnRequest FSM to assert/deassert TurnRequest signal.

Figure 7-97. TurnRequest FSM

The DSI protocol engine asserts TurnRequest signal during one TxClkEsc cycle when the turn-around is enabled through the DSS.[DSI_VCh_CTRL\[6\]](#) BTA_EN bit (for more information, see [Section 7.4.3.8, Bus Turnaround](#)). The DSS.[DSI_TIMING1\[31\]](#) TA_TO bit is set/reset by software to respectively enable/disable the timer for turnaround procedure failure. It can be reset by software or automatically by hardware when the time out occurs.

The timer is loaded with the value in number of DSI_FCLK cycles:

$$\text{DSI_TIMING1[28:16] TA_TO_COUNTER} \times ((\text{DSI_TIMING1[30] TA_TO_X16} \times 15) + 1) \times ((\text{DSI_TIMING1[29] TA_TO_X8} \times 7) + 1).$$

When the TA_TO_IRQ interrupt is generated (turn-around timer expired, and procedure failed), the hardware automatically asserts ForceTXStopMode in order for the DSI_PHY to drive LP-11 stop state. The ForceTXStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTXStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.[DSI_CTRL\[0\]](#) IF_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for DSS.[DSI_TIMING1\[15\]](#) FORCE_TX_STOP_MODE_IO and DSS.[DSI_CTRL\[0\]](#) IF_EN bits to be reset to 0 before starting the recovery sequence.

7.4.3.7.4 Peripheral Reset Timer

The peripheral reset timer is not implemented in the DSI protocol engine module. Such as the Twakeup timer, a general-purpose timer (GPTimer)should be used in case of reset of the peripheral to determine when the peripheral is ready again for operation.

7.4.3.7.5 HS TX Timer

The HS TX timer is used to detect when the host has been in TX mode for too long. When time-out occurs, the EOT is forced. The timer is reloaded when a start of high speed transmission occurs. It is enabled/disabled by software through the DSS.[DSI_TIMING2\[31\]](#) HS_TX_TO bit. The interrupt HS_TX_TO_IRQ is generated when the timer expires. The DSS.[DSI_IRQSTATUS\[14\]](#) HS_TX_TO_IRQ bit is set to 1 when the HS TX time-out occurs.

The maximum time to be supported is 20 ms. It can be used to determine that at least once a frame in video mode, the HS mode is stopped to enter ULPS. Since the refresh rate can be up to 50 frames per second in video mode, the maximum time in HS is 20 ms.

The timer is loaded with the value in number of TxByteClkHS:

$DSI_TIMING2[28:16] \text{ HS_TX_TO_COUNTER} \times ((DSI_TIMING2[30] \text{ HS_TX_TO_X16} \times 15) + 1) \times ((DSI_TIMING2[29] \text{ HS_TX_TO_X8} \times 7) + 1)$

Figure 7-98. High-Speed TX Timer FSM

dss-174

When the time-out occurs, the hardware should sent EOT request in order for the DSI complex I/O to drive LP-11 stop state. This is followed by the generation of the interrupt. The hardware will perform an internal logic reset including the TX FIFO content, but excluding the register values and then resets the DSS.DSI_CTRL[0] IF_EN bit.

The software should wait for the DSS.DSI_CTRL[0] IF_EN bit to be reset to 0 before taking any recovery action by resetting for example the peripheral if it is not responding.

7.4.3.7.6 LP RX Timer

When the host is in Low power Receive mode after a bus turn-around, the LP RX timer is loaded. When the timer expires, the host requests the DSI complex I/O to drive LP-11. The interrupt LP_RX_TO_IRQ is generated when the timer expires. The DSS.DSI IRQSTATUS[15] LP_RX_TO_IRQ bit is set to 1 when the LP RX time-out occurs.

The DSS.DSI_TIMING2[15] LP_RX_TO bit is set/reset by the software to respectively enable/disable the timer.

The timer is loaded with the value in number of DSI_FCLK cycles:

$DSI_TIMING2[12:0] \text{ LP_RX_TO_COUNTER} \times ((DSI_TIMING2[14] \text{ LP_RX_TO_X16} \times 15) + 1) \times ((DSI_TIMING2[13] \text{ LP_RX_TO_X4} \times 3) + 1)$

Figure 7-99. Low-Power RX Timer FSM

When the interrupt is generated, the hardware should automatically reset the DSS.[DSI_TIMING2\[15\]](#) LP_RX_TO bit and then assert ForceTxStopMode in order for the DSI complex I/O to drive LP-11 stop state. The ForceTxStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTxStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.[DSI_CTRL\[0\]](#) IF_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for the DSS.[DSI_TIMING1\[15\]](#) FORCE_TX_STOP_MODE_IO and DSS.[DSI_CTRL\[0\]](#) IF_EN bits to be reset before starting the recovery sequence. The TX FIFO is not flushed (the FIFO is flushed only when DSS.[DSI_VCh_CTRL\[0\]](#) VC_EN is set to 1).

7.4.3.8 Bus Turnaround

The bus turn-around (BTA) is not automatically sent by default after each packet sent to the display(s). It is programmable independently for each VC ID. The VC can be enabled when DSS.[DSI_VCh_CTRL\[6\]](#) BTA_EN bit is set to 1 by software. The software should ensure that, when the BTA is sent to the peripheral, there is enough time allocated for the response and the BTA from the peripheral to host. For more information about possible DSI PHY timing adjustments during the turn-around procedure, see [Section 7.5.6.4.3, Turn-Around Request in Transmit Mode](#), and [Section 7.5.6.4.4, Turn-Around Request in Receive Mode](#). When setting the DSS.[DSI_VCh_CTRL\[6\]](#) BTA_EN bit to 1, one BTA is sent manually to the peripheral. This manual mode can be used for packets in command or video mode.

Acknowledgment from the peripheral for successful BTA is indicated by asserting the BTA_IRQ interrupt, if it is enabled in the DSS.[DSI_VCh_IRQENABLE\[5\]](#) BTA_IRQ_EN bit. To monitor the BTA interrupt, the user should read the DSS.[DSI_VCh_IRQSTATUS\[5\]](#) BTA_IRQ status bit.

CAUTION

The BTA should not be sent when the RX FIFO is not empty. Users should take care of emptying the RX FIFO before sending BTA to the peripheral. It is to ensure that when receiving new data from peripheral, all the allocated spaces for all the VCs are empty.

In automatic mode, the BTA is sent automatically at the end of short or long packets when respectively the DSS.[DSI_VCn_CTRL\[2\]](#) BTA_SHORT_EN or the DSS.[DSI_VCn_CTRL\[3\]](#) BTA_LONG_EN bits are set to 1.

NOTE: If the DSS.[DSI_VCn_CTRL\[2\]](#) BTA_SHORT_EN bit is enabled, users can still set the DSS.[DSI_VCn_CTRL\[6\]](#) BTA_EN bit. Only one BTA is sent to the peripheral and the DSS.[DSI_VCn_CTRL\[6\]](#) BTA_EN bit is reset by hardware.

If the DSS.[DSI_VCn_CTRL\[3\]](#) BTA_LONG_EN bit is enabled, users can still set the DSS.[DSI_VCn_CTRL\[6\]](#) BTA_EN bit. Only one BTA is sent to the peripheral and the DSS.[DSI_VCn_CTRL\[6\]](#) BTA_EN bit is reset by hardware.

If the DSS.[DSI_VCn_CTRL\[2\]](#) BTA_SHORT_EN and DSS.[DSI_VCn_CTRL\[3\]](#) BTA_LONG_EN bits are both enabled, users can still set the DSS.[DSI_VCn_CTRL\[6\]](#) BTA_EN bit to send a BTA. Only one BTA is sent and the DSS.[DSI_VCn_CTRL\[6\]](#) BTA_EN bit is reset by hardware.

As explained previously, two modes can be used for each VC ID:

- Automatic: After each packet, a bus turn-around is sent. To determine the size of the long packet, the protocol engine on the host side should read the word count defined in the header (in DSS.[DSI_VCn_LONG_PACKET_HEADER](#) register) and use it to determine the last data to be sent on the DSI link. For short packets, the size is always 4 bytes. Then the bus turn-around is sent to the peripheral. The word count is also used to determine how many bytes should be transferred from the 32-bit writes access to the payload register (DSS.[DSI_VCn_LONG_PACKET_PAYLOAD](#) register).
- Manual: In case of data transfer using the L4 interconnect port, while all data have been provided to the DSI protocol engine, users can select bus turn-around for the last packet provided to the L4 interconnect port only by setting the bus turn-around enable bit (DSS.[DSI_VCn_CTRL\[6\]](#) BTA_EN) or for last packets and following ones by setting the automatic mode; in case of data transfer using the video port, the bus turnaround enable bit (DSS.[DSI_VCn_CTRL\[6\]](#) BTA_EN) can be selected at any time during the transfer of the packet. In case of video mode packets (data and synchronization events) users cannot determine when the BTA is sent relatively the video mode packets, so it is highly recommended to use manual BTA mode only for packets generated in command mode but it is possible to use BTA when for a VC in video mode. In case of data provided on the video port, an interrupt for end of packet transfer (PACKET_SENT_IRQ) is provided to indicate users when the packet has been completely sent by the DSI complex I/O. The PACKET_SENT_IRQ can be monitored in [DSI_VCn IRQSTATUS\[2\]](#) PACKET_SENT_IRQ status bit. Users can request BTA even if the space allocated in the TX FIFO for the corresponding VC is empty. It can be sent later on even if there was no packet sent before BTA request. The DSS.[DSI_VCn_CTRL\[6\]](#) BTA_EN bit should be reset by hardware if the BTA request has been sent even if the automatic mode for this specific type of packets is enabled.

The bus turnaround is supported for video mode packets and for command mode packets. It is not possible to send BTA during the blanking periods of the video mode when HS blanking packets should be sent, that is, when one of the following bits is set to 1:

- DSS.[DSI_CTRL\[20\]](#) BLANKING_MODE
- DSS.[DSI_CTRL\[21\]](#) HFP_BLANKING_MODE
- DSS.[DSI_CTRL\[22\]](#) HBP_BLANKING_MODE
- DSS.[DSI_CTRL\[23\]](#) HSA_BLANKING_MODE

Therefore, in video mode, the BTA request is delayed until there is a blanking period without HS blanking packets.

TA Timer

When TurnRequest signal is asserted (always only for data lane #1), the TA_TO timer is started. If the direction signal is not changed according to the turn-around request, the TA_TO interrupt is generated. When the Direction signal is in output mode, any data on the input data bus should be ignored since the DSI is in transmission mode (data and triggers should be ignored). See [Section 7.4.3.7.3](#) for more details on the TA_TO timer.

7.4.3.9 PHY Triggers

The DSI protocol engine uses three triggers, which are supported only for data lane 1:

- Reset from host to display
- Tearing effect (TE) from display to host
- Acknowledge from display to host

CAUTION

Each trigger is associated with a dedicated user-configurable receive or transmit pattern, loaded in [DSI_PHY_REGISTER3](#) or [DSI_PHY_REGISTER4](#) bit fields. The default (reset) values of the bit fields are aligned with the MIPI D-PHY specification v0.92. If the user needs to change any of these values, the following must be considered:

- If any of the bit fields are written with a nondefault value, the other bit fields in the same register must also be configured with different values. This is to ensure that two different trigger bit fields are not programmed with the same pattern.
- If two or more bit fields are written with equal values, this may lead to unpredictable behavior of the DSI PHY module.

7.4.3.9.1 Reset

The DSI protocol engine can use one of the triggers of the DSI_PHY to send a reset to the display. The reset trigger pattern is configurable through the [DSI_PHY_REGISTER3\[31:24\]](#) REG_TXTRIGGERESC3 bit field. To send the reset pattern to the peripheral, the DSS.[DSI_CTRL\[5\]](#) TRIGGER_RESET bit must be set to 1. When the software requires the trigger reset pattern to be sent, the DSI protocol engine resets its own logic but not the registers. The software can select between two reset modes:

- Immediate reset: All pending requests in TX FIFO not already taken into account for transfer scheduling, the RX FIFO requests, and the data from video port are ignored. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.
- Synchronized reset: The mode is only valid if there is VC using the video mode and if it is active. The principle is to wait for the current video frame to be transferred on the link. Any data on VP after the current frame are ignored.

To select the reset mode, software users must program the DSS.[DSI_CTRL\[14\]](#) TRIGGER_RESET_MODE.

CAUTION

For both reset modes, the hardware should flush the FIFOs, synchronization buffers, and line buffers before resetting the DSS.[DSI_CTRL\[0\]](#) IF_EN bit.

7.4.3.9.2 Tearing Effect

The TE on the display is avoided by having synchronization information from the display. It is used only in command mode. In case of video mode, it is not functional. Users are responsible for selecting the command mode for the VC using the TE feature.

The software must set and send the appropriate sequence to receive the TE trigger pattern from the peripheral. The value of the expected TE trigger pattern can be configured through the [DSI_PHY_REGISTER4\[23:16\]](#) REG_RXTRIGGERESC2 bit field. When the TE trigger pattern is received, the DSI protocol engine generates the TE_TRIGGER_IRQ interrupt with TE event if the interrupt is enabled. To enable the interrupt, set to 1 the DSS.[DSI_IRQENABLE\[16\]](#) TE_TRIGGER_IRQ_EN bit. The DSS.[DSI_IRQSTATUS\[16\]](#) TE_TRIGGER_IRQ status bit indicates if the interrupt event has been generated.

One or multiple VCs can be synchronized using the same TE trigger. The DSS.[DSI_VCn_TE\[30\]](#) TE_EN bit should be set to indicate that the hardware should use the following TE trigger to start the transfer of the data from the related VC. This bit is reset when all the data have been sent to the peripheral. The DSS.[DSI_VCn_TE\[31\]](#) TE_START bit should be used when the automatic mode enabled by setting the DSS.[DSI_VCn_TE\[30\]](#) TE_EN bit is not used. It allows users to start the transfer manually based on application events or based on the TE trigger interrupt (TE_TRIGGER_IRQ).

The number of bytes to be transferred is defined by using the DSS.[DSI_VCn_TE\[15:0\]](#) TE_SIZE bit field. The TE_SIZE bit field is decremented for each payload byte (it does not include Check-sum) sent on the DSI link. The register content should not be modified by software during a transfer. The DSS.[DSI_VCn_TE\[15:0\]](#) TE_SIZE bit field should be set first to indicate that the following accesses to DSS.[DSI_VCn_LONG_PACKET_HEADER](#) register should be used for TE transfer.

The data can be provided from two sources (selection by setting the DSS.[DSI_VCn_CTRL\[1\]](#) SOURCE bit):

- L4 interconnect port using DMA request: The DMA request DSI_DMA_REQ*i* (*i*=0 to 3) to should be asserted only when TE trigger is received or when the DSS.[DSI_VCn_TE\[31\]](#) TE_START bit is set by user and should not be asserted anymore when all the bytes defined in DSS.[DSI_VCn_TE\[15:0\]](#) TE_SIZE bit field have been sent on the DSI link. The VC is associated with a DMA request (from DSI_DMA_REQ0 to DSI_DMA_REQ3) by programming the number in the DSS.[DSI_VCn_CTRL\[23:21\]](#) DMA_TX_REQ_NB bit field. The DSS.[DSI_VCn_LONG_PACKET_PAYLOAD](#) register is used to provide the number of bytes defined by the DSS.[DSI_VCn_TE\[15:0\]](#) TE_SIZE bit field (the check-sum value is not provided in the DSS.[DSI_VCn_LONG_PACKET_PAYLOAD](#) register). The size of the header is not taken into account in the number of bytes to transfer. The DSS.[DSI_VCn_SHORT_PACKET_HEADER](#) register is not used.
- Video port: The DMA request is not asserted. The data are captured in the line buffer using the STALL mechanism. In case there is no line buffer instantiated (that is, DSS.[DSI_CTRL\[13:12\]](#) LINE_BUFFER bit field set to 0), it is not possible to use the video port to provide data. The line buffer should be filled up according to the word count defined in the DSS.[DSI_VCn_LONG_PACKET_HEADER](#) register header. The value should be written before the TE trigger event is received or before the DSS.[DSI_VCn_TE\[31\]](#) TE_START bit is set to 1 by software. In case the total number of bytes defined by the DSS.[DSI_VCn_TE\[15:0\]](#) TE_SIZE bit field is not a multiple of the word count defined in the DSS.[DSI_VCn_LONG_PACKET_HEADER](#) register, all the packets have the same size defined by the WC of the header except the last transfer. The size of the last transfer is defined by the remaining bytes to send. Since the DSS.[DSI_VCn_TE\[15:0\]](#) TE_SIZE bit field is modified after each packet transfer, the size of the last packet is equal to the value of DSS.[DSI_VCn_TE\[15:0\]](#) TE_SIZE bit field just before the last transfer (the header and the payload check-sum sizes are not included in DSS.[DSI_VCn_TE\[15:0\]](#) TE_SIZE bit field).

When the transfer is completed, the value of the DSS.[DSI_VCn_TE\[15:0\]](#) TE_SIZE bit field is equal to 0. The software must ensure that the pending data in the TX FIFO for the corresponding VC using TE are related to TE transfer. Any data in the TX FIFO that should be sent before reception of TE trigger should be sent before TE. This is done by not enabling TE trigger until all data for the corresponding VC have been sent to the peripheral. The software can check that the space allocated for the VC in the TX FIFO is empty by reading the DSS.[DSI_VCn_CTRL\[5\]](#) TX_FIFO_NOT_EMPTY status bit.

7.4.3.9.3 Acknowledge

The corresponding Acknowledge interrupt (ACK_TRIGGER_IRQ) is generated upon reception of the acknowledge trigger. The value of the expected acknowledge trigger pattern can be configured through the [DSI_PHY_REGISTER4\[15:8\]](#) REG_RXTRIGGERESC1 bit field. To enable the acknowledge interrupt, set the DSS.[DSI_IRQENABLE\[17\]](#) ACK_TRIGGER_IRQ_EN bit to 1. When the interrupt is generated, the DSS.[DSI_IRQSTATUS\[17\]](#) ACK_TRIGGER_IRQ status bit is set to 1.

7.4.3.10 ECC Generation

The DSI protocol uses a four-byte packet header. Since ECC generation requires a fixed word length of 64-bits, the packet headers should be padded with additional bits to form a full eight-byte value for ECC generation and checking. The packet header less the ECC byte should occupy bits D[23:0] and the pad bits should occupy bits D[63:24]. All padding bits should be zero for the purpose of generating the ECC byte. ECC can be generated using a parallel approach as illustrated in [Figure 7-100](#).

Figure 7-100. 64-Bit ECC Generation on TX Side

dss-176

The ECC generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The DSS.[DSI_CTRL\[2\]](#) ECC_RX_EN bit enables/disables the ECC generation in the receive direction.
- The DSS.[DSI_VCn_CTRL\[8\]](#) ECC_TX_EN bit enables/disables the ECC generation in the transmit direction

7.4.3.11 Checksum Generation for Long Packet Payloads

Long packets are comprised of a packet header protected by an ECC byte and a payload of 0 to $2^{16} - 1$ bytes. To detect the errors during the transmission of long packets, a checksum is calculated over the payload portion of the data packet. Note that, for the special case of a zero-length payload, the 2-byte checksum is set to 0xFFFF. The checksum can only indicate the presence of one or more errors in the payload. Unlike ECC, the checksum does not enable error correction. For this reason, checksum calculation is not useful for some unidirectional DSI implementations since the peripheral has no way for reporting errors to the host processor. Checksum generation and transmission is mandatory for host processors sending long packets to peripherals. It is optional for peripherals transmitting long packets to the host processor. However, the format of long packets is fixed; the peripherals that do not support checksum generation should transmit two bytes having value 0x0000 in place of the checksum bytes when sending long packets to the host processor. The host processor should disable checksum checking for received long packets from peripherals that do not support checksum generation.

The checksum should be realized as a 16-bit CRC with a generator polynomial of $x^{16}+x^{12}+x^5+x^0$. The LS byte is sent first, followed by the MS byte. Note that within the byte, the LS bit is sent first.

Figure 7-101. Checksum Transmission

dss-177

The CRC implementation is presented in [Figure 7-102](#). The CRC shift register is initialized to 0xFFFF

before packet data enters. Packet data not including the packet header then enters as a bitwise data stream from the left, LS bit first. Each bit is fed through the CRC shift register before it is passed to the output for transmission to the peripheral. After all bytes in the packet payload have passed through the CRC shift register, the shift register contains the checksum. C15 contains the checksums MSB and C0 the LSB of the 16-bit checksum. The checksum is then appended to the data stream and sent to the receiver.

Figure 7-102. 16 Bit CRC Generation Using a Shift Register

The check-sum generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The DSS.[DSI_CTRL\[1\]](#) CS_RX_EN bit enables/disables the check-sum generation in the receive direction.
- The DSS.[DSI_VCn_CTRL\[7\]](#) CS_TX_EN bit enables/disables the check-sum generation in the transmit direction

7.4.3.12 End of Transfer Packet

To allow the DSI protocol (rather than the DSI_PHY) at the display to detect the HS End Of Transfer (EOT), an EOT packet type is added. It is a fixed short packet (4 bytes) that is added at every HS-to-LP transition. This function is enabled by the [DSI_CTRL\[19\]](#) EOT_ENABLE bit.

The EOT packet has a fixed format:

- Data Type = DI [5:0] = 0b001000
- Virtual Channel = DI [7:6] = 0b00
- Payload Data [15:0] = 0x0F0F
- ECC [7:0] = 0x01

When more than one data lane is used, the bytes in the EOT packet are distributed across multiple lanes. EOT packet generation is supported only for the end of HS transmissions. No EOT packet is added at the end of LP transmissions. For LP reception, any EOT packet received is simply passed through the same as any other packet, but no internal decode or use is made of the EOT information.

7.4.4 DSI PLL Controller Functionalities

7.4.4.1 DSI PLL Controller Overview

The DSI PLL controller module forms part of the display sub-system. Nevertheless, it uses the SCP (Serial Configuration Port) and PMP (Power Management Port) ports as the primary interfaces to the DSI protocol engine. The SCP interface is used to set the configuration of the DPPLL and HSDIVIDER modules, primarily the various counter values. The PMP port is used to control the power state of the DPPLL and HSDIVIDER modules. [Figure 7-103](#) provides an overview of the DSI PLL controller module inside the display subsystem.

The DSI PLL is also used to generate the 74.25-MHz frequency used for HDTV applications.

Figure 7-103. DSI PLL Controller Overview

dss-179

NOTE: The DSI PLL controller module does not have an interface to L4 interconnect. The programmable features are managed by registers mapped into the DSI protocol engine.

7.4.4.2 DSI PLL Controller Architecture

The DSI PLL is an ADPLL module. The pixel clock (PCLK) frequency range is 2 to 68.25 MHz. This may be divided by 2. This is performed by setting the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFREQ bit to 1.

Figure 7-104 shows the internal DSI PLL reference diagram.

Figure 7-104. DSI PLL Reference Diagram

camdss-180

NOTE: PCLK is inverted as the falling edge is the reference edge and ADPLL uses positive edge as reference (F/F should be positive edge clock also).

The DSI PLL clock output corresponds to the CLKIN4DDR clock of the DSI complex I/O module.

The DSI PLL reference clock is the DSI_PLL_REFCLK clock. Depending on the setting in DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit, the reference clock can be either the DSS2_ALWON_FCLK provided by the PRCM or the PCLKFREE provided by the DISPC module.

7.4.4.3 DSI PLL Operations

The signals of the DSI PLL configuration operate according to [Table 7-37](#). The values in the table indicate the operation when the PLL is not locked.

Table 7-37. DSI PLL Operation Modes When Not Locked

DSI PLL Operation Mode	Stop mode Low power ⁽¹⁾	Stop mode Fast Relock ⁽¹⁾	Idle bypass
Mode Description	Output clocks stopped Lowest power standby	Output clocks stopped Fastest start-up time	Selects when PLL and HSDIVIDER bypass clocks are used
DSS.DSI_PLL_CONFIGURATION2[0] DSI_PLL_IDLE	0	0	1
DSS.DSI_PLL_CONFIGURATION2[6] DSI_PLL_LOWCURRSTBY	1	0	1
DSS.DSI_PLL_CONFIGURATION1[0] DSI_PLL_STOPMODE	1	1	X

⁽¹⁾ Recommended

When locked, the PLL output frequency is: $[(2x\text{REGM})/(\text{REGN} + 1)] \times [\text{CLKin}(MHz)/(HIGHFREQ + 1)]$ where:

- M multiplier is programmed in DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM bit field.
- N divider is programmed in DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN bit field.
- HIGHFREQ divider by 2 is enabled by setting the DSS.DSI_PLL_CONFIGURATION2[12]

DSI_PLL_HIGHFREQ bit to 1.

7.4.4.4 DSI PLL Controller Shadowing Mechanism

The configuration registers are accessed through the DSI protocol engine register space using SCP port. This includes all the configuration signals and the returning status signals.

CAUTION

All writes must be 32-bit operations as the SCP always transfers 32 bits. Any 16-bit or 8-bit operations may lead to unpredictable errors.

A shadow mechanism is implemented for appropriate register values so that configurations may optionally be updated in synchronism with the display controller (DISPC) and DSI protocol engine. The front porch time from the DISPC indicates the time when making the update of the value. All the required updated values must have been written before this signal is asserted. See [Section 7.4.3.5.1](#) for more details.

7.4.4.5 Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.[DSI_PLL_STATUS](#)[1] DSI_PLL_LOCK status bit gives the DSI PLL lock state.
- The DSS.[DSI_PLL_STATUS](#)[2] DSI_PLL_RECAL status bit informs if the PLL must be uncalibrated

These signals can also generate interrupts at DSI protocol engine level:

- The PLL_LOCK_IRQ interrupt indicates that the DSI PLL control module has sent a lock request to the DSI PLL. To monitor this event, read the DSS.[DSI_IRQSTATUS](#)[7] PLL_LOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_UNLOCK_IRQ interrupt indicates that the DSI PLL control module has sent an unlock request to the DSI PLL. To monitor this event, read the DSS.[DSI_IRQSTATUS](#)[8] PLL_UNLOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_RECAL_IRQ interrupt indicates that the DSI PLL control module has sent a recalibration request to the DSI PLL. To monitor this event, read the DSS.[DSI_IRQSTATUS](#)[9] PLL_RECAL_IRQ bit. Set this bit to 1 to clear the status bit.

7.4.5 DSI Complex I/O Functionalities

7.4.5.1 DSI Complex I/O Overview

DSI_PHY is a complex I/O with 3 unidirectional (HS) Lane Modules. This includes 2 data lane modules and 1 clock lane module. Each lane module has 2 data pads (DX, DY). These data pads are connected with a complementary lane module on the DSI receiver device using point to point interconnect.

Lane modules support high-speed burst mode. Forward direction and reverse direction escape modes are also supported. Escape modes maybe used for Low Power Data Transmission, among other things.

The maximum data rate supported is 900 Mbps per data lane. The lane module function and position is configurable, that is, any lane module can be chosen as clock lane module, and DX/DY data pad for each lane module can be configured as either DP or DN pins defined by DSI_PHY spec.

DSI_PHY interacts with the higher layers of the DSI link through the PHY-Protocol Interface (PPI). DSI_PHY does not include a PLL; a high frequency clock input is expected in HS mode (CLKIN4DDR). DSI_PHY supports also Serial Configuration Protocol (SCP) to set various configuration and control registers. The DSI_PHY supports GPIO operation on each of the six data pins.

7.4.6 RFBI Functionalities

The RFBI module can capture the output pixel from the display controller and send the data to the RFB in the LCD panel. The application configures the RFBI module, sends commands, reads data, and configures the display controller to send data fetched from the system memory by the display controller DMA engine. The commands/data are sent using an 8-, 9-, 12-, or 16-bit parallel interface.

The display controller is configured to send the data in 12-, 16-, 18-, or 24-BPP format. In the video port FIFO, the encoded pixel values are in an LSB alignment independently of the endianness in system memory.

[Figure 7-105](#) shows an overview of the RFBI architecture.

Figure 7-105. RFBI Architecture Overview

dss-053

7.4.6.1 RFBI FIFO

The input video port FIFO receives data from the display controller at the pixel clock. The data in the video port FIFO are read by the RFBI and are sent to the LCD panel. The video port FIFO is 24 bits wide and each pixel in 12-, 16-, 18-, and 24-BPP format is stored in the video port FIFO using one 24-bit value aligned on the 24-bit LSB. [Section 7.4.6.4, Output Parallel Modes](#), shows an example of an output configuration based on the interface width (16 bits) and the pixel format output (24 bits).

7.4.6.2 RFBI Interconnect FIFO

The interconnect FIFO receives the data from [RFBI_DATA](#) write requests to the L4 interconnect slave port. The data in the interconnect FIFO are read by the RFBI and sent to the LCD panel. The width of the interconnect FIFO is 32 bits. The size of the interconnect FIFO is 24 words of 32 bits (that is, 24 words of [RFBI_DATA](#)).

7.4.6.3 Input Pixel Formats

The supported pixel formats in the RFBI module are: RGB24-888, RGB18-666, RGB16-565, and RGB12-444 as output from the display controller and from the L4 (for writing parameters). In both cases, the pixels are formatted in accordance with the configuration of the output interfaces (multiple cycles).

7.4.6.4 Output Parallel Modes

The RFBI output modes are 8-, 9-, 12-, and 16-bit interfaces. Any mode can be selected regardless of the pixel format. Set the right configuration in the cycle registers to define a valid configuration for each output cycle.

The following example is an output configuration based on the 16-bit interface width and the 24-bit pixel format ($i = 0$ or 1) (see also [Table 7-38](#)):

- The DSS.[RFBI_CONFIG\[10:9\]](#) CYCLEFORMAT bit field is set to $0x3$ (three cycles for two pixels).
- The DSS.[RFBI_DATA_CYCLE1_i](#) register is set to $0x00000010$ (16 bits from pixel 1 for the first cycle).
- The DSS.[RFBI_DATA_CYCLE2_i](#) register is set to $0x00080808$ (8 bits from pixel 1 and pixel 2 and alignment of 8 bits from pixel 2 for the second cycle).
- The DSS.[RFBI_DATA_CYCLE3_i](#) register is set to $0x00100000$ (16 bits from pixel 2 for the third cycle).

Table 7-38. 16-Bit Interface Configuration/24-Bit Mode

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle
Data[15]	R0[7]	B0[7]	G1[7]
Data[14]	R0[6]	B0[6]	G1[6]
Data[13]	R0[5]	B0[5]	G1[5]
Data[12]	R0[4]	B0[4]	G1[4]
Data[11]	R0[3]	B0[3]	G1[3]
Data[10]	R0[2]	B0[2]	G1[2]
Data[9]	R0[1]	B0[1]	G1[1]
Data[8]	R0[0]	B0[0]	G1[0]
Data[7]	G0[7]	R1[7]	B1[7]
Data[6]	G0[6]	R1[6]	B1[6]
Data[5]	G0[5]	R1[5]	B1[5]
Data[4]	G0[4]	R1[4]	B1[4]
Data[3]	G0[3]	R1[3]	B1[3]
Data[2]	G0[2]	R1[2]	B1[2]
Data[1]	G0[1]	R1[1]	B1[1]
Data[0]	G0[0]	R1[0]	B1[0]

7.4.6.5 Unmodified Bits

In a cycle, if every bit in the interface does not have a pixel value, the status of the unused bits can be programmed to be 0, 1, or the previous value (I/O power consumption optimization).

7.4.6.6 Bypass Mode

In bypass mode, the RFBI path is bypassed and the display controller data and signals are sent directly to the output interface of the RFBI.

7.4.6.7 Send Commands

The commands are written through the L4 interconnect and into the DSS.[RFBI_CMD](#) register. After a command is sent, another one can be accepted by the module and set. If the processing of a command is not complete, the MPU access to change the command stalls.

7.4.6.8 Read/Write

Depending on the status of A0, WE, and RE, the commands and display/parameter data are written to the panel (handled by the state-machine for the commands/parameter data and stored in memory for the display data), or the display data/status values are read from the LCD panel (status and display data in the LCD panel memory). The polarity of A0 (RFBI_A0 signal), WE (RFBI_WR signal), RE (RFBI_RD signal), and CSx (RFBI_CSx signal, with x = 0, 1) is programmable.

[Table 7-39](#) describes the read/write function.

Table 7-39. Read/Write Function Description

A0 (RFBI_A0)	WE (RFBI_WR)	RE (RFBI_RD)	Function Description
1	0	1	Display data write, parameter data write
1	1	0	Display data read
0	1	0	Status read
0	0	1	Command data write

A minimum of RFBI_Cs cycle time, as defined in [Table 7-40](#), is required to keep the RFBI_CSx signal asserted between write transfers of multiple pixels.

[Table 7-40](#) indicates the minimum cycle time for RFBI_CSx, depending on the source of pixels (display controller or L4 interconnect slave port) and the cycle format (1pixel/cycle, 1 pixel/2 cycles, 1 pixel/3 cycles, or 2 pixels/3 cycles).

Table 7-40. Minimum Cycle Time for CSx/WE Always Asserted

RFBI Performance	RFBI_CONFIG[10:9] CYCLEFORMAT	RFBI_CONFIG[8:7] L4FORMAT	Minimum Cycle Time (in Number of L4 Cycles)
L4 interconnect	1 pixel/cycle	1 pixel	5
	1 pixel/2 cycles	1 pixel	4
	1 pixel/3 cycles	1 pixel	4
	2 pixels/3 cycles	1 pixel	6
	1 pixel/cycle	2 pixels	4
	1 pixel/2 cycles	2 pixels	4
	1 pixel/3 cycles	2 pixels	4
	2 pixels/3 cycles	2 pixels	6
Display Controller	1 pixel/cycle	N/A	4
	1 pixel/2 cycles	N/A	3
	1 pixel/3 cycles	N/A	3
	2 pixels/3 cycles	N/A	6

7.4.7 Video Encoder Functionalities

The input formats supported by the encoders are 24-bit 4:4:4 RGB. The encoder output is the DAC stage (for more information, see [Section 7.2, Display Subsystem Environment](#)). In the display subsystem, the input format from the display controller is always 24-bit RGB. The RGB-to-YCbCr color space converter converts the 24-bit RGB pixel data to 24-bit YCbCr data.

The remaining Cb and Cr color components enter the 2-to-1 chrominance decimation, which reduces by half the chrominance bandwidth and the amount of chrominance data. After the data manager, the encoder processes in 4:2:2 data path up to the 2x interpolation. A luma delay synchronizes luma to chrominance data.

[Figure 7-106](#) shows an overview of the video encoder architecture.

Figure 7-106. Video Encoder Architecture Overview

camdss_swpu176-public-079

NOTE: Output video mode can be either composite video (CVBS output) or separate video (S-video: Luma and Chroma outputs):

- Composite video: only AVDAC1 is used
- Separate video (Luma/Chroma): Both AVDAC1 (Luma) and AVDAC2 (Chroma) are used. The selection is programmed with DSS.[DSS_CONTROL\[6\]](#) VENC_OUT_SEL bit. Composite video is the default selection.

7.4.7.1 Test Pattern Generation

For diagnostic purposes, the data manager can be forced to output 100/100 color bar RGB/YCbCr data by setting the SVDS field [VENC_F_CONTROL\[7:6\]](#) register to 0x1.

Table 7-41. 100/100 Color Bar Table

COLOR	R	G	B	Y	Cb	Cr
White	255	255	255	235	128	128
Yellow	255	255	0	210	16	146
Cyan	0	255	255	170	166	16
Green	0	255	0	145	54	34
Magenta	255	0	255	106	202	222
Red	255	0	0	81	90	240
Blue	0	0	255	41	240	110
Black	0	0	0	16	128	128

7.4.7.2 Luma Stage

The luma stage includes a luma pipeline delay, luma shaping, 2x interpolation filter, and luma variable delay. The luma pipeline delay block is used to match luma path length to chroma path length. In the luma gain shaper, a programmable gain is first applied to the luminance data output. The luminance gain is defined by the DSS.[VENC_GAIN_Y](#) register. Horizontal sync, vertical sync, and setup insertion are then performed.

Black level and blank level are programmable through the DSS.[VENC_BLACK_LEVEL](#) and DSS.[VENC_BLANK_LEVEL](#) registers. All the transition edges of the luminance signal, such as sync edges and active video edges, are properly shaped and filtered to keep the bandwidth within the standards.

After all required components of the luminance signal are added, the resulting signal is low-passed and interpolated to 2x-pixel rate. This 2x interpolation simplifies the external analog reconstruction filter design and improves the signal-to-noise ratio.

7.4.7.3 Chroma Stage

The chroma stage includes a low-pass filter, first-stage 2x interpolation, chroma gain shaper, and second-stage 2x interpolation. A pair of programmable gains adjusts the time-multiplexed U/V signal. The gains for U and V are independently controlled by the DSS.[VENC_GAIN_U](#) and DSS.[VENC_GAIN_V](#) register bits.

7.4.7.4 Subcarrier and Burst Generation

The encoder uses a 32-bit subcarrier increment to synthesize the subcarrier. The value of the subcarrier increments required to generate the desired subcarrier frequency for NTSC and PAL format is found by:

$$S_CARR = \text{ROUND} \left([F_{sc}/F_{clkenc}] \times 2^{32} \right)$$

where:

F_{sc} = Frequency of the subcarrier

F_{clkenc} = Frequency of the internal video encoder

The DSS.[VENC_S_CARR](#) register controls the subcarrier frequency. The DSS.[VENC_C_PHASE](#) register controls the phase of the subcarrier. The phase of the color subcarrier is reset to DSS.[VENC_C_PHASE](#). Table 7-42 presents the [VENC_S_CARR](#) register values depending the standard and pixel type used.

Table 7-42. VENC_S_CARR Register Recommended Values

Standard	Pixel Type	Subcarrier Frequency (F_{sc}) (MHz)	F_{clkenc} (MHz)	VENC_S_CARR register value (hexa)
NTSC-M, J	ITU-R601	3.579545	27	0x21F07C1F
PAL-M	ITU-R601	3.5756083125	27	0x21E6EEF3
PAL-B, D, G, H, I	ITU-R601	4.43361875	27	0x2A098ACB
NTSC-M, J	Square pixel	3.579545	24.5454	0x25555555
PAL-M	Square pixel	3.579561149	24.5454	0x1F15C01E
PAL-B, D, G, H, I	Square pixel	4.43361875	29.50	0x26798C0C

CAUTION

In square pixel mode, an external clock generator is needed to provide sampling frequencies (49.09 MHz for NTSC square pixel or 59 MHz for PAL square pixel).

The color subcarrier reset has four modes:

- No reset

- Reset every two lines
- Reset every two fields
- Reset every eight fields

The DSS.VENC_C_PHASE register can be used to adjust the SCH (subcarrier to horizontal sync phase). The DSS.VENC_BSTAMP_WSS_DATA[6:0] BSTAP bit field sets the amplitude of the color burst. The DSS.VENC_M_CONTROL[1] PAL bit enables phase alternation line encoding.

A phase switching subcarrier is generated to encode the chrominance signal when the DSS.VENC_M_CONTROL[1] PAL bit is set to 1. Otherwise, a normal subcarrier is generated. Phase alternation line refers to the encoding scheme in which the subcarrier alternates between two phases every scan line. Two possible alternation sequences are possible, and the DSS.VENC_M_CONTROL[5] PALPHS bit selects one of these sequences.

7.4.7.5 Closed Caption Encoding

The encoder can be programmed to encode closed-caption data and extended data in the selected line. The closed-caption data are sent to the encoder through the L4 interconnect. The data stream consists of 7-bit US-ASCII code and 1 odd-parity bit (see [Table 7-43](#)).

Table 7-43. Closed-Caption Data Format

MSB	LSB						
Bit6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Odd parity

The standard service encodes closed caption in both fields; the extended service encodes closed caption in even fields. When set to 1, the DSS.VENC_L21 wc_CTL L21EN[0] bit enables closed-caption encoding in odd fields. When set to 1, the DSS.VENC_L21 wc_CTL L21EN[1] bit enables closed-caption encoding in even fields.

To select the scan line where the CC data are encoded, program the [VENC_LN_SEL\[4:0\]](#) SLINE bit field.

CAUTION

The setting of the value of the SLINE[4:0] bit field depends on the video standard:

- PAL mode: Because there is a one-line offset, program the desired line number – 1. To activate the closed caption on line 21 (0x15), program the value $0x15 - 1 = 0x14$. The default value is $0x15 + 1 = 0x16$ (line 22).
- NTSC mode: Because there is a four-line offset, program the desired line number – 4. To activate the closed caption on line 21 (0x15), program the value $0x15 - 4 = 0x11$. The default value is $0x15 + 4 = 0x19$ (line 25).

The DSS.VENC_LN_SEL[25:16] LN21_RUNIN bit field should be kept at reset value (0x10B). Four closed-caption data registers contain the data to be encoded. The DSS.VENC_LINE21[15:8] L21O and DSS.VENC_LINE21[7:0] L21O bit fields contain the first and the second bytes, respectively, of closed-caption data to be encoded in the odd field. The DSS.VENC_LINE21[31:24] L21E and DSS.VENC_LINE21[23:16] L21E bit fields contain the first and the second bytes, respectively, of data to be encoded in the even field.

Immediately after the closed-caption data is written to the registers, in either the odd field or even field, the corresponding closed-caption status bit (DSS.VENC_STATUS[4] CCE or DSS.VENC_STATUS[3] CCO) is reset to 0 to indicate that the closed-caption data is available in the closed-caption data registers and yet to be encoded.

Immediately after the closed-caption data is encoded, the DSS.VENC_STATUS[4] CCE bit or the DSS.VENC_STATUS[3] CCO bit is set to 1 to indicate that the closed-caption data has been encoded and is ready to accept new data. As seen in [Figure 7-107](#), a null character is automatically inserted if the closed-caption data is not written to the closed-caption data registers in time for encoding.

The running clock frequency is controlled by the DSS.[VENC_CC_CARR_WSS_CARR\[15:0\]](#) FCC bit field which should be kept at reset value (0x2631) to get 5034960.5Hz (32xline) for NTSC-601. The closed-caption running clock common frequencies are detailed in [Table 7-44](#).

Table 7-44. Closed-Caption Run Clock Frequency Settings

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[15:0] FCC bit field value	0x2631	0x25ED	0x2A03	0x22B6

The closed-caption data is encoded in nonreturn-to-zero (NRZ) format. Additionally, the data translates to the IRE scale as follows: 0 = 0 IRE; 1 = 50 IRE.

[Figure 7-107](#) shows the parameters of closed-caption line data implemented in different standards.

Figure 7-107. Closed Captioning Timing

dss-080

NOTE:

- The interval A is controlled by the DSS.[VENC_LN_SEL\[25:16\]](#) LN21_RUNIN bit field.
- The interval B is controlled by DSS.[VENC_CC_CARR_WSS_CARR\[15:0\]](#) FCC bit field.

Table 7-45. Closed-Caption Standard Timing Values

Intervals	Description	Timing Values for Encoding			Timing Values for Decoding		
		Minimal	Nominal	Maximal	Lower Bound	Nominal	Upper Bound
A	HSYNC to clock running	10.250 μ s	10.500 μ s	10.750 μ s	10.000 μ s	10.500 μ s	11.000 μ s
B	Clock running		12.910 μ s			12.910 μ s	
C	Clock running to third start bit		3.972 μ s			3.972 μ s	
D	Start bit		1.986 μ s			1.986 μ s	
E	Data characters		31.778 μ s			31.778 μ s	

NOTE: All timing values listed in [Table 7-45](#) are measured from the mid-point (half amplitude) on all edges.

For a complete description of copy protection including CGMS-A, please refer to CEA-608-x standard

7.4.7.6 Wide-Screen Signaling (WSS) Encoding

The encoder can embed data, encoded in accordance with the IEC61880 and ITU-R 1119 data insertion standard, within the vertical blanking interval.

The encoder supports WSS data insertion on line 20 of every frame in the NTSC format. WSS data insertion is enabled by activating the DSS.[VENC_L21_WC_CTL](#)[14:13] EVEN_ODD_EN bit and by programming the [VENC_BSTAMP_WSS_DATA](#)[27:8] WSS_DATA bit field.

The running clock frequency is controlled by the DSS.[VENC_CC_CARR_WSS_CARR](#)[31:16] FWSS bit field. The wide-screen signaling running clock common frequencies are detailed in [Table 7-46](#)

Table 7-46. Wide-Screen Signaling Run Clock Frequency Settings

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR [31:16] FWSS bit field value	0x043F	0x2F72	0x04AC	0x2B6D

To select the line where the WSS data are encoded, program the DSS.[VENC_L21_WC_CTL](#)[12:8] LINE bit field.

CAUTION

The setting of the LINE[12:8] bit field value depends on the video standard:

- PAL mode: There is an one line offset, so program the wanted line number - 1. The recommended value is line $0x16 + 1 = 0x17$ (23rd line). Note that the default value is $0x14 + 1 = 0x15$ (21st line).
- NTSC mode: There is a four line offset, so program the wanted line number - 4. The recommended value is line $0x10 + 4 = 0x14$ (20th line). Note that the default value is $0x14 + 4 = 0x18$ (24th line).

The WSS encoding block assumes that a full 10-bit video range is used to determine the 70 percent of peak-white amplitude of a logic-1 bit. The encoder also supports WSS data insertion on line 23 in the PAL format. Both waveforms are shown in [Figure 7-108](#).

Figure 7-108. WSS Timing

dss-081

7.4.7.7 Video DAC Stage – Architecture and Control

[Figure 7-109](#) shows the architecture of the video DAC stage, comprising two 10-bit video DACs (AVDAC1 and AVDAC2) instances.

Figure 7-109. Video DAC Stage Architecture

dss-082

The display subsystem provides the necessary control signals to interface the memory frame buffer directly to external displays (TV sets). Two (one per channel) 10-bit current steering AVDAs are used to generate the video analog signal:

- AVDAC1: Carries either the CVBS (composite) or S-Video Luma (Y) analog TV outputs; it provides also the TV detection/disconnection and power-down mode features.
- AVDAC2 : Carries only the S-Video Chroma (C) analog TV output.

The device system control module provides two dedicated AVDAC registers, CONTROL.CONTROL_AVDAC1 and CONTROL.CONTROL_AVDAC2, to configure the respective channels through the following bit field:

- CONTROL.CONTROL_AVDACx [20:16] AVDACx_COMP_EN: Allows direct control over the configuration of the analog TV output. See [Table 7-47](#), [Section 7.5.8, Video Encoder Basic Programming Model](#), and [Chapter 13, System Control Module](#).

Table 7-47. Analog TV Output Control

Register CONTROL.CONTROL_AVDACx [x=1, 2]	Description
[19] AVDACx_COMP_EN	Single or dual channel operation 0: Single channel (default) 1: Dual channel
[18] AVDACx_COMP_EN	Channel role 0: Luma video channel (dual-channel configuration) or Composite video channel (single-channel configuration) (default) 1: Chroma video channel (dual-channel configuration)

Table 7-47. Analog TV Output Control (continued)

Register CONTROL.CONTROL_AVDACx [x=1, 2]	Description
[17] AVDACx_COMP_EN	Full scale swing selection 0: High full-scale output swing: 1.3 V (default) 1: Low full-scale output swing: 0.88 V
[16] AVDACx_COMP_EN	Current reference selection 0: External current reference (set by external resistor connected to cvideo1_rset pin) (default) 1: Internal current reference

CAUTION

Any change to the control register must be done only when the respective VDAC is off.

High full-swing mode is the default mode. Low-swing mode does not comply with the NTSC and PAL video standards. It must be used only for backward compatibility to the OMAP35x.

7.4.7.8 Video DC/AC Coupled TV Load

The 10-bit video DAC stage supports both DC-coupled and AC-coupled TV loads. The CONTROL.CONTROL_DEVCONF1[11] TVACEN bit is used to define which output coupling is used (0: DC coupling; 1: AC coupling). This bit is the first one to be programmed according to the TV load on the PCB board.

NOTE: In high-swing mode, when DC coupling is used, there is a 180-mV DC offset at the TVOUT output (cvideo1_out for AVDAC1 and cvideo2_out for AVDAC2).

In low-swing mode, when DC coupling is used, the DC offset at the maximum DAC code (@Max DAC current ~500 μ A) is 300 mV.

7.4.7.9 TV Detection/Disconnection Pulse Generation and Usage**7.4.7.9.1 TV Detection/Disconnection Pulse Generation**

The TV detect block is an integral part of the video DAC stage.

NOTE:

- The TV detection/disconnection feature is supported only for AVDAC1.
 - The TV disconnection feature is recommended to save power. The TV detection/disconnection is operational only when video out is active. Therefore, to detect cable connection automatically, it is necessary to periodically activate the video out to test for cable presence.
-

This block compares the output of AVDAC1 (cvideo1_out) to a reference, to sense the condition of the load. To operate, the TV detect requires two digital signals, TVACEN and TVDET. The TVACEN signal indicates to both TVOUT buffer and the TV detect circuit if the load is AC or DC coupled to adjust accordingly. To enable the detection of the load, the video encoder generates a negative TVDET pulse aligned with the TV sync pulses. The operation of the circuit is based on the difference in voltage levels in the output of the buffer depending on the load status. The TV detect block compares the output against a couple of references and the result is latched at the start of every sync pulse. The status, given by the TVINT output bit, is read later with the TVDET pulse rising edge. The TVINT signal of AVDAC1 is internally connected to channel 1 of the GPIO2 module, mapped as the TV detector interruption.

The following registers are used to set the TV detection/disconnection pulse:

- The DSS.[VENC_TVDETGP_INT_START_STOP_X](#) register defines which pixels are used to start and stop the pulse inside their respective line.
- The DSS.[VENC_TVDETGP_INT_START_STOP_Y](#) register defines which lines are used to start and stop the pulse.
- The DSS.[VENC_GEN_CTRL\[0\]](#) EN bit enables or disables the TVDET pulse (0: Disable; 1: Enable).
- The DSS.[VENC_GEN_CTRL\[16\]](#) TVDP bit sets the TVDET pulse polarity (0: Active low; 1: Active high).

7.4.7.9.2 TV Detection Procedure

The TV detection procedure is the following:

1. Initial setup:
 - Program the DSS.[VENC_TVDETGP_INT_START_STOP_X](#) and DSS.[VENC_TVDETGP_INT_START_STOP_Y](#) registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
 - Set the DSS.[VENC_GEN_CTRL\[16\]](#) TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
 - Set the DSS.[VENC_GEN_CTRL\[0\]](#) EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.[VENC_TVDETGP_INT_START_STOP_X](#) and DSS.[VENC_TVDETGP_INT_START_STOP_Y](#) registers.
3. Set the [VENC_OUTPUT_CONTROL\[0\]](#) LUMA_ENABLE bit (in s-video mode) or the [VENC_OUTPUT_CONTROL\[1\]](#) COMPOSITE_ENABLE (in composite video mode) to 1 to enable the video DAC1 output.
4. Power up the vdda_dac voltage for the DAC stage and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I²C interface connected to the power IC.
5. The TVDET pulse is set high by hardware according to the settings in the DSS.[VENC_TVDETGP_INT_START_STOP_X](#) and DSS.[VENC_TVDETGP_INT_START_STOP_Y](#) registers.
6. Check the TVINT output signal: When TVINT is set to 1, the load is connected.

CAUTION

- If AC coupling is selected, two TVDET pulses are required to set high the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If DC coupling is selected, only one TVDET pulse is required to set high the TVINT signal.

7.4.7.9.3 TV Disconnection Procedure

The TV disconnection procedure is the following:

1. Initial setup:
 - Program the DSS.[VENC_TVDETGP_INT_START_STOP_X](#) and DSS.[VENC_TVDETGP_INT_START_STOP_Y](#) registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
 - Set the DSS.[VENC_GEN_CTRL\[16\]](#) TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
 - Set the DSS.[VENC_GEN_CTRL\[0\]](#) EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.[VENC_TVDETGP_INT_START_STOP_X](#) and DSS.[VENC_TVDETGP_INT_START_STOP_Y](#)

registers.

3. The TVDET pulse is set high by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
4. Check the TVINT output signal: When TVINT is reset to 0, the load is disconnected.
5. Reset the VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit (in s-video mode) or the VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE (in composite video mode) to 0 to disable the video DAC1 output.
6. Power-down the vdda_dac voltage for the DAC stage and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I²C interface connected to the power IC.

CAUTION

- If DC coupling is selected, two TVDET pulses are required to set low the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If AC coupling is selected, only one TVDET pulse is required to set low the TVINT signal.

7.4.7.9.4 Recommended TV Detection/Disconnection Pulse Waveform

To enable the detection/disconnection of the load, the circuit requires that the TVDET pulse resembles the following waveform. As explained in [Section 7.4.7.9.2, TV Detection Procedure](#), and in [Section 7.4.7.9.3, TV Disconnection Procedure](#) by using the video encoder registers, the TVDET pulse polarity, start and stop is programmable. The only critical parameter is Tdm, which should be longer than the delay through the AVDAC and TVOUT buffer, which is at least 750 ns.

If DC-coupling is selected, the TVINT output signal for TV detection is latched at the rising edge of the first TVDET signal but the TVINT output signal for TV disconnection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing. [Figure 7-110](#) shows the waveforms for the DC-coupling TV detect pulse (TVDET) when load is connected and disconnected.

Figure 7-110. DC-Coupling TV Detect Waveforms for TV Connected and Disconnected

dss-083

If AC-coupling is selected, the TVINT output signal for TV detection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing but the TVINT output signal for TV disconnection is latched at the rising edge of the first TVDET signal. [Figure 7-111](#) shows the waveforms for the AC-coupling TV detect pulse (TVDET) when load is connected and disconnected.

Figure 7-111. AC-Coupling TV Detect Waveforms for TV Connected and Disconnected**NOTE:**

- When setting the DSS.VENC_TVDETGP_INT_START_STOP_X register, software users must ensure that the TVDET signal is in the active area. To avoid any problem, the TVDET signal must not be longer than one line.
- The activation of the TVDET signal will not have a visual impact on the cvideo1_out output signal.

7.4.7.9.5 TV Detection/Disconnection Usage

The TV-detection/TV-disconnection is based on the difference in voltage levels in the output of the TV buffer depending on the load status. The operation is slightly different for ac and for dc operation. For DC operation, the cvideo1_out voltage is compared against a voltage reference that makes the comparator trigger in each sync pulse while the load is connected. For AC operation, the cvideo1_out voltage is compared against a voltage reference that makes the comparator trigger in each sync pulse while the load is disconnected. In both cases, the TVINT output signal produces a logic 1 when a load is connected and a logic 0 when a load is disconnected.

For DC-coupling mode, see [Figure 7-112](#) and for AC-coupling mode, see [Figure 7-113](#).

NOTE: Because the video DAC stage and the video encoder must be awake for connection detection, consider that the video DAC stage can take up to 10 μ s to wake up.

Figure 7-112. GPIO Signal Waveform Proposal for TV Detection/Disconnection in DC-Coupling Mode

Figure 7-113. GPIO Signal Waveform Proposal for TV Detection/Disconnection in AC-Coupling Mode

7.4.7.10 Video DAC Stage Bypass Mode

The 10-bit video DAC stage has a TVOUT buffer bypass mode that turns off the TVOUT buffers and redirects directly the outputs of the DACs to the VFB pins (cvideo1_vfb for AVDAC1 and cvideo2_vfb for AVDAC2).

This bypass mode is activated by setting the CONTROL.CONTROL_DEVCONF1[18] TVOUTBYPASS bit to 1. The reset value of the CONTROL.CONTROL_DEVCONF1[18] TVOUTBYPASS bit is 0 (that is, the TVOUT buffer is not bypassed).

NOTE: In bypass mode:

- The cvideo1_rset pin requires a Rset resistor connected to the ground. The typical value of the Rset resistor is 10K.
- Both cvideo1_vfb and cvideo2_vfb pins require a Rout resistors connected to the ground. The typical values of Rout1 and Rout2 resistors are 1,5K.

CAUTION

- The TV detect feature is not available in bypass mode.
- In bypass mode, an external amplifier is needed on the cvideo1_vfb and cvideo2_vfb pins.

7.4.7.11 Video DAC Stage Test Mode

The DAC stage can be tested for debug using either 10-bit external data or 10-bit internal register values directly connected to the DACs. See [Figure 7-114](#) for video DAC test in composite video mode, and see [Figure 7-115](#) for video DAC test in separate video mode.

Figure 7-114. DAC Test Mode in Composite Video Mode

dss-087

Figure 7-115. DAC Test Mode in Separate video Mode

dss-088

- Use the DSS.VENC_OUTPUT_CONTROL[4] TEST_MODE bit to select between DAC normal mode (0x0) and DAC test mode (0x1).
- Use the DSS.VENC_OUTPUT_CONTROL[7] CHROMA_SOURCE bit for AVDAC2 and either the DSS.VENC_OUTPUT_CONTROL[6] COMPOSITE_SOURCE bit (in composite video mode) or the DSS.VENC_OUTPUT_CONTROL[5] LUMA_SOURCE bit (in s-video mode) for AVDAC1 to select the test mode:
 - 0x0: From the internal register DSS.VENC_OUTPUT_TEST[25:16] CHROMA_TEST bit field for AVDAC2 and either DSS.VENC_OUTPUT_TEST[9:0] COMPOSITE_TEST bit field (composite video) or DSS.VENC_OUTPUT_CONTROL[25:16] LUMA_TEST (s-video mode) for AVDAC1
 - 0x1: From the video port G[1:0], B[7:0]

NOTE: In the external data test mode (bypass mode), the display controller must provide the data (G[1:0], B[7:0]) externally. To do this, configure the video encoder to generate correct timing signals, without which the display controller cannot operate (even if the encoder core is bypassed from the data path perspective).

7.4.7.12 Video DAC Stage Power Management

After device reset, the DSS_CONTROL[5] DAC_POWERDN_BGZ register bit is set to 0, and the video DAC stage is powered down.

Table 7-48 shows possible power management configurations and the corresponding register settings.

Table 7-48. Video DAC Stage Power Management

Power Management Controls						
DSS_CONTROL[5] DAC_POWERD_N_BGZ	AVDAC2 VENC_OUTPUT_CONTROL[2] CHROMA_ENABLE	AVDAC1 VENC_OUTPUT_C ONTROL[1] COMPOSITE_ENA BLE	VENC_OUTPUT _CONTROL[0] LUMA_ENABLE	CONTROL_DEV CONF1[18] TVOUTBYPASS	CONTROL_D EVCONF1[11] TVACEN	Description
0	x	x	x	x	x	Total power down. Bandgaps powered down.
1	0	0	0	x	x	Standby (analog in power down except bandgaps/LDOs)
1	1	1	1	0	0	Full power up in DC mode
1	1	1	1	0	1	Full power up in AC mode
1	1	1	1	1	x	Full power up in TVOUT bypass mode (DAC-only mode)

7.5 Display Subsystem Basic Programming Model

This section describes how to configure the display subsystem for the desired functionalities and also describes the programming models of the display controller, the RFBI and the video encoder.

The main configuration scenarios are:

- LCD panel support (bypass or RFBI mode)

Configure the RFBI module (only if in RFBI mode; otherwise, the default values must remain), and then configure the display controller to the desired functionalities before the activities start.

- TV set support

Configure the video encoder and then the display controller.

- Both LCD panel support (bypass or RFBI mode) and TV set support

Configure the RFBI module (only if in RFBI mode; otherwise, leave the default values), configure the video encoder, and then configure the display controller.

7.5.1 Display Subsystem Reset

The display subsystem can receive a software reset that is propagated through all of the submodules to initialize the subsystem. The following procedure describes a possible sequence:

1. If the LCD is on, stop the LCD by setting the DSS.[DISPC_CONTROL\[0\]](#) LCDENABLE bit to 0.
 - (a) Reset the frame done status bit by writing 1 in the DSS.[DISPC_IRQSTATUS\[0\]](#) FRAMEDONE bit.
 - (b) Wait until the DSS.[DISPC_IRQSTATUS\[0\]](#) FRAMEDONE bit is set to 1. This shows that the end of frame has taken place and the LCD stop is complete.
2. To take the display subsystem out of reset, all clocks related to the display subsystem must be enabled and the DPLL4 must be enabled. The following clocks must be enabled to take the display subsystem out of reset:
 - PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit set to 1
 - PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit set to 1
 - PRCM.CM_FCLKEN_DSS[2] EN_TV bit set to 1
 - PRCM.CM_ICLKEN_DSS[0] EN_DSS bit set to 1Once the clocks are enabled as shown, the display subsystem can be taken out of reset.
3. Write 1 in the DSS.[DSS_SYSCONFIG\[1\]](#) SOFTRESET bit to apply the soft reset to the subsystem.
4. Read the DSS.[DSS_SYSSTATUS\[0\]](#) RESETDONE bit. If this bit is 1, the reset sequence is complete; otherwise, read this bit again (the reset sequence is not completed).

7.5.2 Display Subsystem Configuration Phase

The display subsystem configuration phase is important to configure the data flow for using the LCD panel or the TV set. Use the following flow:

1. To configure the top level of the functional clock of the display controller clock, set the DSS.[DSS_CONTROL\[0\]](#) DSS_CLK_SWITCH bit.
2. To configure the top level of the video encoder, set the DSS.[DSS_CONTROL\[2\]](#) VENC_CLOCK_MODE bit and the DSS.[DSS_CONTROL\[3\]](#) VENC_CLOCK_X4 bit for TV set support.
3. To configure the top level of the DAC stage, set the DSS.[DSS_CONTROL\[4\]](#) DAC_DEMEN bit for TV set support (if required).
4. Configure the RFBI module and/or the video encoder as needed.
5. Configure the display controller.

7.5.3 Display Controller Basic Programming Model

Some display controller registers are termed *shadow registers*, which are associated with the digital output and/or the LCD output. A shadow register change has no direct effect on the configuration of the display controller unless the DSS.[DISPC_CONTROL\[5\]](#) GOLCD bit is set for the LCD output and/or the DSS.[DISPC_CONTROL\[6\]](#) GODIGITAL bit is set for the digital output.

In the case of the digital output, after programming the shadow registers, the DSS.[DISPC_CONTROL](#)[6] GODIGITAL bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the external EVSYNC.

In the case of the LCD output, after programming the shadow registers, the DSS.[DISPC_CONTROL](#)[5] GOLCD bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the VFP start period.

Before setting either the DSS.[DISPC_CONTROL](#)[5] GOLCD or DSS.[DISPC_CONTROL](#)[6] GODIGITAL bit, ensure that the bit is cleared.

[Table 7-49](#) lists the shadow registers.

Table 7-49. Shadow Registers

Shadow Register Name	Updated on VFP Start Period (LCD output)	Updated on External VSYNC (Digital output)
DSS. DISPC_CONTROL	X ⁽¹⁾	X ⁽¹⁾
DSS. DISPC_CONFIG	X	X
DSS. DISPC_DEFAULT_COLOR_m (m = 0)	X

DSS.DISPC_DATA_CYCLEk (k = 0 to 3)	X	

7.5.3.1 Display Controller Configuration

The following registers define the display controller configuration:

- DSS.DISPC_SYSCONFIG
- DSS.DISPC_SYSSTATUS
- DSS.DISPC_IRQSTATUS
- DSS.DISPC_IRQENABLE

7.5.3.2 Graphics Layer Configuration

The graphics layer configuration is common to the LCD and the TV set.

7.5.3.2.1 Graphics DMA Registers

The following registers define the graphics DMA engine configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_GFX_BA_j
- DSS.DISPC_GFX_ATTRIBUTES
- DSS.DISPC_GFX_ROW_INC
- DSS.DISPC_GFX_PIXEL_INC
- DSS.DISPC_GFX_FIFO_THRESHOLD
- DSS.DISPC_GFX_TABLE_BA

The following fields define the attributes of the graphics DMA engine:

- Graphics layer enable (DSS.DISPC_GFX_ATTRIBUTES[0] GFXENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The graphics DMA engine fetches encoded pixels from the system memory only when the graphics layer is enabled (a valid configuration is programmed for the graphics layer). The graphics window is present and the graphics pipeline is active.
- Burst size (DSS.DISPC_GFX_ATTRIBUTES[7:6] GFXBURTSIZE field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC_GFX_ATTRIBUTES[11] GFXFIFOPRELOAD bit): The default preload configuration uses the DSS.DISPC_GFX_PRELOAD register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC_GFX_ATTRIBUTES[11] GFXFIFOPRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008,

respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:

- Active matrix (TFT) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0x60 (value is 96)
- Color passive matrix (STN) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0x72 (value is 114)
- Monochrome passive matrix (STN) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0xE0 (value is 224)
- Base address of the graphics buffer in system memory (DSS.DISPC_GFX_BAj registers): The default value of these two registers at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on a pixel size boundary. In case of 4 BPP, the resolution is two pixels; for 2 BPP, resolution is four pixels; for 1 BPP, resolution is eight pixels; and for RGB24 packed format, the resolution is four pixels. The vertical resolution is one line. The register DSS.DISPC_GFX_BA0 defines the base address of the even field; and DSS.DISPC_GFX_BA1 defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Graphics FIFO threshold (DSS.DISPC_GFX_FIFO_THRESHOLD register): The low threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC_CONFIG[14] FIFOERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD bit field) and the high threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD bit field) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the DSS.DISPC_CONFIG[14] FIFOERGE bit reset value is 0).
- Palette/gamma table used (DSS.DISPC_CONFIG[3] PALETTEGAMMABLE bit): The bit indicates if the palette must be loaded before the graphics data for the following frame. The bit is set by software and reset by hardware.
- Base address of the palette/gamma table buffer in system memory (DSS.DISPC_GFX_TABLE_BA register): The default value of this register at reset time is 0x0. The base address is aligned on a 32-bit address. Depending on the pixel size of graphics data (1, 2, 4, or 8 BPP), 16 (1, 2, or 4 BPP), or 256 (8 BPP) x 32-bit values are loaded from system memory into the internal table memory. To load the table when using the memory as a gamma table, the graphics pipeline is enabled and then disabled by the software when the palette loaded interrupt is generated. The overlay manager ignores the graphics pipe when the table is used as a gamma table.

NOTE: In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

- Graphics Priority (DSS.DISPC_GFX_ATTRIBUTES[14] GFXARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the graphics channel vs. video channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Graphics Self-Refresh (DSS.DISPC_GFX_ATTRIBUTES[15] GFXSELFREFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame
- Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
- Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

The sequence to deactivate the self-refresh is the following:

- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
- Frame t+1: Fetch of the data from system memory using the L3 interconnect

7.5.3.2.2 Graphics Layer Configuration Registers

The following registers define the graphics layer configuration:

- DSS.[DISPC_CONFIG](#)
- DSS.[DISPC_GFX_POSITION](#)
- DSS.[DISPC_GFX_SIZE](#)
- DSS.[DISPC_GFX_ATTRIBUTES](#)

The graphics layer is enabled/disabled by setting/resetting the DSS.[DISPC_GFX_ATTRIBUTES](#)[0] GFXENABLE bit. When the graphics layer is disabled, the graphics window does not exist on the screen and the graphics pipeline and DMA are inactive.

Set a valid configuration before enabling the graphics layer. After a register change, either the DSS.[DISPC_CONTROL](#)[6] GODIGITAL or DSS.[DISPC_CONTROL](#)[5] GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

7.5.3.2.3 Graphics Window Attributes

The following fields define the attributes of the graphics window:

- Graphics format (DSS.[DISPC_GFX_ATTRIBUTES](#)[4:1] GFXFORMAT bit field): The default value of this bit field at reset time is 0x0 (BITMAP 1-BPP). The graphics format can be either: BITMAP1, BITMAP2, BITMAP4, or BITMAP8 (CLUT) or RGB12, RGB16, or RGB24 (true-color formats).
- Graphics window X-position (DSS.[DISPC_GFX_POSITION](#)[10:0] GFXPOSX bit field): The default value at reset time is 0x0. The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Graphics window Y-position (DSS.[DISPC_GFX_POSITION](#)[26:16] GFXPOSY bit field): The default value of this bit field at reset time is 0x0. The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Graphics window width (DSS.[DISPC_GFX_SIZE](#)[10:0] GFXSIZEX bit field): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed for the following formats: 8 BPP, RGB12, RGB16, and RGB24. The width must be a multiple of eight pixels for 1 BPP, four pixels for 2 BPP, and two pixels for 4 BPP. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width of the graphics window (in bytes) is a multiple of the graphics burst size defined in the DSS.[DISPC_GFX_ATTRIBUTES](#)[7:6] GFXBURSTSIZE bit field (in bytes).

NOTE: When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.[DISPC_GFX_ROW_INC](#) register is not 1. When DSS.[DISPC_GFX_ROW_INC](#) register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the graphics window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the graphics layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

- Graphics window height (DSS.[DISPC_GFX_SIZE](#)[26:16] GFXSIZEY bit field): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the graphics window must be inside the LCD screen. Depending on the height of the buffer to be displayed in the graphics layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen
- Graphics data endianness (DSS.[DISPC_GFX_ATTRIBUTES](#)[10] GFXENDIANNESS bit): This bit indicates the endianness (little or big) of the graphics pixels. The default value at reset time is 0x0 (little endian).
- Graphics data nibble mode (DSS.[DISPC_GFX_ATTRIBUTES](#)[9] GFXNIBBLEMODE bit): This bit

indicates the nibble mode of the graphics pixels. The default value at reset time is 0x0 (Disable).

- Graphics replication logic enable (DSS.[DISPC_GFX_ATTRIBUTES](#)[5] GFXREPLICATIONENABLE bit): The default value at reset time is 0x0 (Disable). The encoded pixel data in RGB format (RGB16) can be extended to 24-bit format with or without replication of the MSB part to fill up the LSB due to the 24-bit left alignment. If the replication logic is turned off, the LSB part is filled up with 0s.
- Graphics window skip enable (DSS.[DISPC_CONTROL](#)[12] OVERLAYOPTIMIZATION bit): By setting/resetting the bit, the overlay optimization is enabled or disabled. Before enabling the overlay optimization, the DSS.[DISPC_GFX_WINDOW_SKIP](#)[31:0] GFXWINDOWSKIP bit field must be set according to the video1 and graphics windows overlap. The default value at reset time is 0x0 (Disable). When video1 is not present, the DSS.[DISPC_GFX_WINDOW_SKIP](#)[31:0] GFXWINDOWSKIP bit field should be reset. When the color key is used, the DSS.[DISPC_GFX_WINDOW_SKIP](#)[31:0] GFXWINDOWSKIP bit field should be reset.
- Graphics window skip (DSS.[DISPC_GFX_WINDOW_SKIP](#)[31:0] GFXWINDOWSKIP bit field): The bit field represents the number of bytes to skip while fetching the graphics-encoded pixels when reaching the beginning of the video window. The optimization allows fetching only the visible graphics pixels. The color key cannot be selected because the graphics pixels under the video window are not present. The default value at reset time is 0x0 (0 byte).

[Figure 7-116](#) through [Figure 7-119](#) give examples of how to program the GFXWINDOWSKIP field for overlay optimization:

7.5.3.3 Video Layer Configuration

The video layer configuration is common to the LCD and the TV set.

7.5.3.3.1 Video DMA Registers

The following registers define the video DMA engine configuration:

- DSS.[DISPC_CONTROL](#)
- DSS.[DISPC_VIDn_BAj](#)
- DSS.[DISPC_VIDn_ATTRIBUTES](#)
- DSS.[DISPC_VIDn_ROW_INC](#)
- DSS.[DISPC_VIDn_PIXEL_INC](#)
- DSS.[DISPC_VIDn_FIFO_THRESHOLD](#)
- DSS.[DISPC_VIDn_PICTURE_SIZE](#)

The following fields define the attributes of the graphics DMA engine:

- Video layer enable (DSS.[DISPC_VIDn_ATTRIBUTES\[0\]](#) VIDENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The video DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration is programmed for the video layer). The video window is present and the video pipeline is active.
- Burst size (DSS.[DISPC_VIDn_ATTRIBUTES\[15:14\]](#) VIDBURSTSIZEx bit field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This bit field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests, because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.[DISPC_VIDn_ATTRIBUTES\[19\]](#) VIDFIFOPRELOAD bit): The default preload configuration uses the DSS.[DISPC_VIDn_PRELOAD](#) register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.[DISPC_VIDn_ATTRIBUTES\[19\]](#) VIDFIFOPRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:
 - Active matrix (TFT) display: DSS.[DISPC_VIDn_PRELOAD\[11:0\]](#) PRELOAD = 0xB0 (value is 176)
 - Color passive matrix (STN) display: DSS.[DISPC_VIDn_PRELOAD\[11:0\]](#) PRELOAD = 0x110 (value is 272)
 - Monochrome passive matrix (STN) display: DSS.[DISPC_VIDn_PRELOAD\[11:0\]](#) PRELOAD = 0x1B0 (value is 432)

- Base address of the video buffer in system memory (DSS.[DISPC_VIDn_BAj](#) registers): The default value at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on pixel size boundary. In case of YCbCr 4:2:2 formats, the resolution is 2 pixels. In case of RGB24 packed format, the resolution is 4 pixels. The vertical resolution is one line. The register DSS.[DISPC_VIDn_BA0](#) defines the base address of the even field, and DSS.[DISPC_VIDn_BA1](#) defines the base of the odd field in the case of an external synchronization and based on the value of the input signal [DISPC_FID](#) and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Video FIFO threshold (DSS.[DISPC_VIDn_FIFO_THRESHOLD](#) register): The low threshold (DSS.[DISPC_VIDn_FIFO_THRESHOLD\[11:0\]](#) VIDFIFOLOWTHRESHOLD) and the high threshold (DSS.[DISPC_VIDn_FIFO_THRESHOLD\[27:16\]](#) VIDFIFOHIGHTHRESHOLD) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.[DISPC_CONFIG\[14\]](#) FIFOMERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the DSS.[DISPC_VIDn_FIFO_THRESHOLD\[11:0\]](#) VIDFIFOLOWTHRESHOLD bit field with n corresponding to the active video channel 1 or 2) and the high threshold (DSS.[DISPC_VIDn_FIFO_THRESHOLD\[27:16\]](#) VIDFIFOHIGHTHRESHOLD bit field with n corresponding to the active video channel 1 or 2) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the DSS.[DISPC_CONFIG\[14\]](#) FIFOMERGE bit reset value is 0).
- Video buffer width (DSS.[DISPC_VIDn_PICTURE_SIZE\[10:0\]](#) VIDORGSIZEX): The default value at reset time is 0x0 (1 pixel). The buffer width in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this bit field to the value minus 1.
- Video buffer height (DSS.[DISPC_VIDn_PICTURE_SIZE\[26:16\]](#) VIDORGSIZEY): The default value at reset time is 0x0 (1 pixel). The buffer height in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this field to the value minus 1.
- Video data endianness (DSS.[DISPC_VIDn_ATTRIBUTES\[17\]](#) VIDENDIANNESS bit, with n=1 or 2): This bit indicates the endianness (little or big) of the video pixels. The default value at reset time is 0x0 (little endian).

7.5.3.3.2 Video Configuration Register

The following shadow registers define video layer n (with n = 1 or 2) configuration:

- DSS.[DISPC_CONFIG](#)
- DSS.[DISPC_VIDn_POSITION](#)
- DSS.[DISPC_VIDn_SIZE](#)
- DSS.[DISPC_VIDn_ATTRIBUTES](#)
- DSS.[DISPC_VIDn_FIR](#)
- DSS.[DISPC_VIDn_PICTURE_SIZE](#)
- DSS.[DISPC_VIDn_FIR_COEF_Hi](#) (with i = 0 to 7)
- DSS.[DISPC_VIDn_FIR_COEF_HVi](#) (with i = 0 to 7)
- DSS.[DISPC_VIDn_CONV_COEFi](#) (with i = 0 to 4)
- The video layer n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.[DISPC_VIDn_ATTRIBUTES\[0\]](#) VIDENABLE field. If the video layer is disabled, the video window does not exist on the screen and the whole video pipeline and DMA are inactive. Before enabling the video layer, a valid configuration must be set. After a register change, either the DSS.[DISPC_CONTROL\[6\]](#) GODIGITAL or DSS.[DISPC_CONTROL\[5\]](#) GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting this bit. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

7.5.3.3.3 Video Window Attributes

The following fields define the attributes of video window n:

- Video format (DSS.DISPC_VIDn_ATTRIBUTES[4:1] VIDFORMAT bit field, with n = 1 or 2): The default value at reset time is 0x0 (BITMAP 1 BPP, non-supported format by the video pipeline). The video format can be RGB16, RGB24, YUV2 4:2:2 co-DSS sited, and UYVY 4:2:2 co-sited.
- Video window X-position (DSS.DISPC_VIDn_POSITION[10:0] VIDPOSX bit field, with n = 1 or 2): The default value at reset time is 0x0 (first column starting on the left edge of the screen). The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Video window Y-position (DSS.DISPC_VIDn_POSITION[26:16] VIDPOSY bit field, with n = 1 or 2): The default value at reset time is 0x0 (first row starting at the top of the screen). The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Video window width (DSS.DISPC_VIDn_SIZE[10:0] VIDSIZEX bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video window is a multiple of the video burst size defined in the DSS.DISPC_VIDn_ATTRIBUTES[15:14] VIDBURSTSIZEx bit field (in bytes).

NOTE: When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC_VIDn_ROW_INC register is not 1. When the DSS.DISPC_VIDn_ROW_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the video window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

- Video window height (DSS.DISPC_VIDn_SIZE[26:16] VIDSIZEY bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the video window must be inside the LCD screen. Depending on the height of the buffer to be displayed in the video layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen.
- Video picture width in system memory (DSS.DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed with RGB16 and RGB24 video data. For YUV2 4:2:2 and UYVY 4:2:2 formats, the width must be a multiple of two pixels. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video picture is a multiple of the video burst size defined in the DSS.DISPC_VIDn_ATTRIBUTES[15:14] VIDBURSTSIZEx bit field (in bytes).
- Video picture height in system memory (the DSS.DISPC_VIDn_PICTURE_SIZE[26:16] VIDORGSIZEY bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed.
- Video Priority (DSS.DISPC_VIDn_ATTRIBUTES[23] VIDARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the video channel vs. other channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Video Self-Refresh (DSS.DISPC_VIDn_ATTRIBUTES[24] VIDSELFREFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame
 - Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
 - Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels
- The sequence to deactivate the self-refresh is the following:
- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame

- Frame t+1: Fetch of the data from system memory using the L3 interconnect

7.5.3.3.4 Video Up-/Down-Sampling Configuration

The video horizontal up/downsampling block for video pipeline n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.[DISPC_VIDn_ATTRIBUTES\[5\]](#) VIDRESIZEENABLE bit.

The video vertical up/downsampling block for video pipeline n is enabled/disabled by setting/resetting the DSS.[DISPC_VIDn_ATTRIBUTES\[6\]](#) VIDRESIZEENABLE bit.

Set a valid configuration before enabling the video up/downsampling block.

NOTE: Vertical and horizontal downsampling are limited to a 1/4 resize factor.

After a register change, either the DSS.[DISPC_CONTROL\[6\]](#) GODIGITAL or DSS.[DISPC_CONTROL\[5\]](#) GOLCD bit must be set. The software must wait until the hardware resets this bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

The following fields define the configuration of the video up/downsampling block for video pipeline n:

- Vertical up/downsampling increment value (DSS.[DISPC_VIDn_FIR\[27:16\]](#) VIDFIRVINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRVINC}[12:0] = 1024 \times \left(\frac{\text{VIDORGSIZEY}[10:0]}{\text{VIDSIZEY}[10:0]} \right)$$

dss-E093

(10)

NOTE:

- If the VIDFIRVINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEY[10:0] equals 0x1, VIDSIZEY[10:0] is replaced by 0x2 in the previous equation.
- The VIDORGSIZEY[10:0] and VIDSIZEY[10:0] bit field values must be programmed with the value desired minus 1.
- Horizontal up/downsampling increment value (DSS.[DISPC_VIDn_FIR\[11:0\]](#) VIDFIRHINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRHINC}[12:0] = 1024 \times \left(\frac{\text{VIDORGSIZEX}[10:0]}{\text{VIDSIZEX}[10:0]} \right)$$

dss-E094

(11)

NOTE:

- If the VIDFIRHINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEX[10:0] equals 1, VIDSIZEX[10:0] is replaced by 2 in the previous equation.
- The VIDORGSIZEX[10:0] and VIDSIZEX[10:0] bit field values must be programmed with the value desired minus 1.
- Vertical up/downsampling accumulator value (DSS.[DISPC_VIDn_ACCUI\[25:16\]](#) VIDVERTICALACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the vertical filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see [Table 7-50](#)).
- Vertical up/downsampling line buffer configuration (DSS.[DISPC_VIDn_ATTRIBUTES\[22\]](#) VIDLINEBUFFERSPLIT bit): The default value at reset time is 0x0 (line buffers are not split). The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, each line buffer is split into two line buffers to be able to use six line buffers instead of three.
- Vertical up/downsampling line buffer configuration (DSS.[DISPC_VIDn_ATTRIBUTES\[21\]](#) VIDVERTICALTAPS bit): The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used. The backward compatibility is maintained versus

OMAP2420 and OMAP2430 devices. When the bit field is set, the 5-tap configuration is used and the DSS.[DISPC_VIDn_ATTRIBUTES\[22\]](#) VIDLINEBUFFERSPLIT bit must be set to 1.

- Vertical up/downsampling line buffer configuration (DSS.[DISPC_VIDn_ATTRIBUTES\[20\]](#) VIDDMAOPTIMIZATION bit): The default value at reset time is 0x0 (no optimization). If the bit is set, the DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV4:2:2) while doing 90- and 270-degree rotation. If the bit is clear, the DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV4:2:2) while doing 90- and 270-degree rotation. The width and height of picture should be even to use the optimization. Even width is required for the input picture when the 5-tap configuration is used.

NOTE: If the 5-tap resizer is used for RGB16 and YUV4:2:2 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

[DISPC_VIDn_ATTRIBUTES\[21\]](#) VIDVERTICALTAPS == 1

[DISPC_VIDn_PICTURE_SIZE\[10:0\]](#) VIDORGSIZEX 4 and even

For more information about the configuration of video DMA optimization, see [Section 7.5.3.4.5, Video DMA Optimization](#).

- Horizontal up/downsampling accumulator value (DSS.[DISPC_VIDn_ACCU\[9:0\]](#) VIDHORIZONTALACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the horizontal filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see [Table 7-50](#)).

Table 7-50. Vertical/Horizontal Accumulator Phase

Accumulator Value	Phases f
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

- Vertical up/downsampling coefficients (DSS.[DISPC_VIDn_FIR_COEF_HVi](#) registers, with n = 1 or 2, i = 0 to 7): The 3-tap vertical up/downsampling coefficients are defined in these registers. There are eight registers for the eight phases with three coefficients for each, or a total of 24 programmable coefficients for the vertical up/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one).

In addition, there are 2-tap vertical up/downsampling coefficients defined in DSS.[DISPC_VIDn_FIR_COEF_Vi](#) registers. There are 8 registers for the 8 phases with 2 coefficients for each of them so a total of 16 programmable coefficients for the vertical up/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients. In case of 5-tap configuration, both sets of registers DSS.[DISPC_VIDn_FIR_COEF_HVi](#) and DSS.[DISPC_VIDn_FIR_COEF_Vi](#) are used. In case of 3-tap configuration, only one set of registers DSS.[DISPC_VIDn_FIR_COEF_HVi](#) is used.

- Horizontal up/downsampling coefficients (DSS.[DISPC_VIDn_FIR_COEF_Hi](#) and [DISPC_VIDn_FIR_COEF_HVi](#) registers, with n = 1 or 2, i = 0 to 7): The DSS.[DISPC_VIDn_FIR_COEF_Hi](#) register and the DSS.[DISPC_VIDn_FIR_COEF_HVi](#) register define the 5-tap horizontal up/downsampling coefficients. There are eight registers for the eight phases with five coefficients for each register, or a total of 40 programmable coefficients for the horizontal up/downsampling block.

Each DSS.[DISPC_VIDn_FIR_COEF_Hi](#) register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one). Each DSS.[DISPC_VIDn_FIR_COEF_HVi](#) register contains one 8-bit signed coefficient.

The programmable coefficient for the FIR up/downsampling method must be adjusted based on application needs. For more details on scaling programming settings, see [Section 7.6.1](#).

7.5.3.3.5 Video Color Space Conversion Configuration

The DSS.DISPC_VIDn_CONV_COEFi registers (with i = 0 to 4) has nine 11-bit coefficients defined for the programmable color space conversion block for video pipeline n (with n = 1 or 2).

The standard register coefficients are:

YCbCr-to-RGB Registers (VidFullRange=0)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dssE095 (12)

YCbCr to RGB Registers (VidFullRange=1)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E096 (13)

[Table 7-51](#) lists the color space conversion register values.

Table 7-51. Color Space Conversion Register Values

Coefficients	BT.601-5	BT.601-5 Range [0:255]	BT.709	BT.709 Range [0:255]

7.5.3.4 Rotation/Mirroring Display Subsystem Settings

This section describes rotation/mirroring settings. The device provides flexible mechanisms for an efficient implementation of rotation using the display-subsystem, its DMA engine, and the rotation engine of the SMS module. Depending on whether the image data is located in on-chip SRAM or external SDRAM, either a DMA rotation or a VRFB rotation is used. When configuring the rotation, the image data format (RGB or YUV) must also be taken into account. The video pipelines also perform the interpolation of YUV image data and the color conversion from YUV into RGB format for displaying the images on an LCD screen.

7.5.3.4.1 Image Data Formats

To understand the programming of the rotation mechanisms described underneath, the supported representations of the image data in memory must also be considered. Differences exist between the supported formats on the graphics and video pipelines. The graphics pipeline supports RGB and RGB with a color look-up table (CLUT), whereas the video pipelines support two versions of YUV 4:2:2 and RGB16. In the case of YUV, the interpolation and color conversion hardware in the video pipelines converts the image data to the RGB format suitable for the LCD screen.

The graphics pipeline supports:

- 1-, 2-, .4-, and 8-bits-per-pixel color look-up table
- 12-, 16-, and 24-bits-per-pixel RGB

The video pipelines support the following data formats (always 2 bytes/pixel):

- RGB16
- YUV2
- UYVY

For more information on the graphics data formats, please refer to [Section 7.4.2.2, Graphics Pipeline](#).

For more information on the video data formats, please refer to [Section 7.4.2.3, Video Pipeline](#).

In the video pipeline, the YUV 4:2:2 format is converted into a full YUV 4:4:4 format by interpolation of the chrominance values from neighboring pixels. After this interpolation is completed, the conversion to the RGB format (suitable for displaying the image on the LCD screen) is performed.

For more information on YUV 4:2:2 to RGB conversion, please refer to [Section 7.4.2.3.2, Color Space Conversion](#).

7.5.3.4.2 Image Data from On-Chip SRAM

For image data located in the on-chip SRAM, the DSS DMA is used to perform 90-degree, 180-degree, and 270-degree rotation. This is done by using the double-indexed addressing mode of the DMA. This addressing mode allows a pixel and a row increment to be specified. These address increments are used after each pixel or each row (line), respectively. [Figure 7-120](#) illustrates the principle steps for a 90-degree rotation.

Figure 7-120. 90° DMA Rotation Example

dss-097

Table 7-52. 90-degree DMA Rotation Example Description

Parameter	Description	Additional parameters for formulas
ba	Buffer Base Address in Memory	
IW	Image Width in pixels	iw = IW-1
IH	Image Height in pixels	ih = IH-1
ps	Pixel Size (in bytes)	

Figure 7-120 shows how the image is stored in memory and how it is read out to achieve a 90-degree rotated orientation. The first pixel for the 0-degree orientation is located at the buffer base address (ba). If the image is to be shown on an LCD screen with a 90-degree rotation, the readout starts at the 90-degree base address (1). To proceed from one pixel to the next in the same line in the rotated orientation, the pixel increment (2) must be applied. At the end of each line of the rotated view, the row increment (3) is the offset to advance to the beginning of the next line in the memory buffer.

Hence, by setting the three DMA parameters (base address, pixel increment, and row increment), a 90-degree rotation can be achieved, as can 180-degree and 270-degree rotation. Each of the parameters can also be combined with an optional mirroring on the vertical axis.

Following there is a description the setup required to perform the rotation via the DSS DMA. This rotation mechanism is used when the image data is stored in internal SRAM.

7.5.3.4.2.1 Rotation/Mirroring Registers

To set up the rotation and/or mirroring, the following registers must be programmed:

- Graphics pipeline (GFX):
 - DSS.[DISPC_GFX_BAj](#)
 - DSS.[DISPC_GFX_PIXEL_INC](#)
 - DSS.[DISPC_GFX_ROW_INC](#)
 - DSS.[DISPC_GFX_ATTRIBUTES](#)
 - DSS.[DISPC_GFX_POSITION](#)
 - DSS.[DISPC_GFX_SIZE](#)
 - DSS.[DISPC_GFX_FIFO_THRESHOLD](#)
- Video pipelines (VID) 1 and 2:
 - DSS.[DISPC_VIDn_BAj](#)
 - DSS.[DISPC_VIDn_PIXEL_INC](#)
 - DSS.[DISPC_VIDn_ROW_INC](#)
 - DSS.[DISPC_VIDn_ATTRIBUTES](#)
 - DSS.[DISPC_VIDn_POSITION](#)
 - DSS.[DISPC_VIDn_SIZE](#)
 - DSS.[DISPC_VIDn_CONV_COEF0](#) to DSS.[DISPC_VIDn_CONV_COEF4](#)
 - DSS.[DISPC_VIDn_FIFO_THRESHOLD](#)
- DSS.DISPC_xxx_BAj: These registers contain the base address of the image data at which the DSS DMA transfer of the image starts. The register values depend on the rotation chosen (see [Table 7-53](#) for the formulas). When using the LCD interface, the registers DISPC_xxx_BA0 are used. The registers DISPC_xxx_BA1 are only used for the TV output.
- DSS.DISPC_xxx_PIXEL_INC[15:0]: This bit field contains the DMA addressing increment after each pixel. This bit field is used to perform the DSS DMA rotation (see [Table 7-53](#) for the formula).

NOTE: When the RGB24 packet format is selected, the only valid value is 1.

- DSS.DISPC_xxx_ROW_INC[31:0]: This bit field contains the DMA addressing increment after each row (line) of pixels. This bit field is used to perform the DSS DMA rotation (see [Table 7-53](#) for the formula).

NOTE: When the RGB24 packet format is selected, the valid values are 1 and any value multiples of 12 bytes (4x32 bit). When the value is a multiple of 12 bytes, the width must be a multiple of 12 bytes. When the value is 1, the width can be any size from 1 to 2048 pixels.

- DSS.DISPC_xxx_ATTRIBUTES: These registers contain the main settings for the pipeline, such as the image data format, the rotation value, and the enable bit for the pipeline. The bit fields of these registers play a role in the rotation and in the image data format setup.
 - The following bit fields are used by the graphics pipeline to set up the image format:
 - GFXENABLE: Set this field to activate the hardware path in use.
 - GFXFORMAT: Use this field to specify the format of the graphic frame.
 - GFXROTATION: Set this field to the value corresponding to the rotation angle desired only if the frame contains RGB24 pixel data; otherwise, set it to 0x0 regardless of the degree of rotation.
 - GFXREPLICATIONENABLE: Use this bit to determine whether the encoded pixel data in RGB formats (RGB12 and RGB16) is extended to 24-bit format with or without replication of the MSB to fill the LSBs of each color component. If the replication logic is turned off, the LSB parts are filled with 0s. It is recommended to always enable this feature.
 - GFXCHANNELOUT: Set this field based on whether the frame is to be rendered on the LCD or on the TV set.
 - The following bit fields for the two video pipelines:
 - VIDENABLE: Set this field to activate the hardware path in use.
 - VIDFORMAT: Use this field to specify the format of the video frame (RGB16 or YUV4:2:2).
 - VIDCOLORCONVENABLE: If the video is in YUV4:2:2 format, set this field to enabled.
 - VIDROTATION: Set this field to the value corresponding to the rotation angle desired only if the frame contains non-RGB pixel data; otherwise, set it to 0x0 regardless of the degree of rotation. See [Section 7.5.3.4.4](#) for more information.
 - VIDROWREPEATENABLE: Set this field to enabled only if the frame contains YUV pixel data and the rotation is 90-degree or 270-degree so that the row pixel data are fetched twice to extract both Y components. See [Section 7.5.3.4.4](#) for more information.
 - VIDCHANNELOUT: Set this field based on whether the frame is to be rendered on the LCD or on the TV set.
 - DSS.DISPC_xxx_POSITION: Use this register to configure the position of the window.
 - DSS.DISPC_xxx_SIZE: Use this register to configure the size of the window.
 - DSS.[DISPC_VIDn_CONV_COEF0](#), DSS.[DISPC_VIDn_CONV_COEF1](#),
DSS.[DISPC_VIDn_CONV_COEF2](#), DSS.[DISPC_VIDn_CONV_COEF3](#), and
DSS.[DISPC_VIDn_CONV_COEF4](#): These registers contain the conversion coefficients required for YUV-to-RGB color conversion.
 - DSS.DISPC_xxx_FIFO_THRESHOLD: Set the low threshold (DSS.[DISPC_GFX_FIFO_THRESHOLD](#)[11:0] GFXFIFOLOWTHRESHOLD) and the high threshold (DSS.[DISPC_GFX_FIFO_THRESHOLD](#)[27:16] GFXFIFOHIGHTHRESHOLD) values to define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. The DMA engine then waits until the low level is reached to restart the requests.

7.5.3.4.2.2 DMA Register Settings

To configure the display controller for rotation and/or mirroring, use the following settings:

Figure 7-121. Rotation/Mirroring Settings

NOTE: These registers are shadow registers. To take into account the new values, software users must set the DSS.[DISPC_CONTROL](#)[5] GOLCD bit to 1.

[Table 7-53](#) details the base address, the row and pixel increment values to access the buffer in memory (contiguous pixels) except for the RGB24 packet format. [Table 7-54](#) lists the rotation register settings for RGB24 packet format (only for the two video pipelines).

Table 7-53. DMA Rotation Register Settings

Rotation	Registers	GFX/VIDx ⁽¹⁾
0 degree	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba 1 1
90 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw x (ih-1) x ps) -(iw x ps) - 1 (iw x (ih-1)) x ps + 1
180 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw x ih-1) x ps -2 x ps -2 x ps

⁽¹⁾

- ba = start address of image buffer in memory
- iw = image width in pixels per row - 1 (for YUV: pixels per row divided by 2)
- ih = image height - 1 (number of rows)
- ps = pixel size in bytes (RGB: 2 bytes per pixel, YUV: 4 bytes per pixel)

See [Table 7-52](#) for more information of these parameters.

Table 7-53. DMA Rotation Register Settings (continued)

Rotation	Registers	GFX/VIDx ⁽¹⁾
270 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw - 1) x ps (iw - 1) x ps + 1 -(iw x (ih-1)) x ps - ps + 1

NOTE: In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

Table 7-54. Video Rotation Register Settings (With RGB24 Packet Format)

Rotation	Registers (with n = 1 or 2)	SDRAM Direct Access ⁽¹⁾
0 degree	DSS.DISPC_VIDn_BAj	ba
	DSS.DISPC_VIDn_PIXEL_INC	1
	DSS.DISPC_VIDn_ROW_INC	1
180 degrees	DSS.DISPC_VIDn_BAj	ba+(iw*ih*3)-4
	DSS.DISPC_VIDn_PIXEL_INC	-7
	DSS.DISPC_VIDn_ROW_INC	-7

⁽¹⁾

- ba = physical base address of the buffer in the system memory (top-left corner of the picture)
- iw = number of pixels per row - 1 (original picture in system memory) for BITMAP and RGB formats and number of pixels per row divided by 2 for YUB422 formats
- h = number of lines - 1 (original picture in system memory)
- ps = pixel size in bytes (BITMAP8: 1 byte; RGB16: 2 bytes; YUV4:2:2: 4 bytes)

See [Table 7-52](#) for more information of these parameters.

The DMA rotation described above can be also combined with an optional mirroring on the vertical axis (see [Figure 7-122](#)). The only settings that must be changed to achieve this mirroring are the registers described above: DISPC_xxx_BAj, DISPC_xxx_PIXEL_INC, and DISPC_xxx_ROW_INC. [Table 7-55](#) provides the DMA setup formulas for rotation with mirroring to access the buffer in memory (contiguous pixels) except for the RGB24 packet format.

Figure 7-122. 90° Rotation With Mirroring

Table 7-55. Register Settings for DMA Rotation With Mirroring

Rotation	Registers	GFX/VIDx ⁽¹⁾
0 degree	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw-1) x ps -2 x ps + 1 2 x (iw-1) x ps + 1
90 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba (iw-1) x ps (-iw x (ih-1)) x ps
180 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + iw x (ih-1) x ps 1 -2 x iw x ps
270 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw x ih - 1) x ps (iw - 1) x ps + 1 - (iw x (ih-1)) x ps - ps + 1

⁽¹⁾

- ba = start address of image buffer in memory
- iw = image width in pixels per row - 1 (for YUV: pixels per row divided by 2)
- ih = image height - 1 (number of rows)
- ps = pixel size in bytes (RGB: 2 bytes per pixel, YUV: 4 bytes per pixel)

See [Table 7-52](#) for more information of these parameters.

7.5.3.4.3 Image Data From External SRAM

The device offers a rotation engine in the SMS called the VRFB. This rotation method must be used for maximum efficiency when the image data is located in SDRAM. To use the VRFB rotation, both the SMS module and the DSS DMA must be configured.

In the DSS, the same registers must be set up as described for DMA rotation (see [Section 7.5.3.4.2, Image Data from On-Chip SRAM](#)). The differences are in the setup of the following registers:

- DISPC_xxx_ROW_INC: This field contains the DMA addressing increment after each row (line) of pixels. This field is used to add the remaining delta at the end of each line, to reach the 2048-pixel line size of the VRFB (see [Table 7-56](#) for the formula).
- DISPC_xxx_PIXEL_INC: This field contains the DMA addressing increment after each pixel. For VRFB rotation, this value is set always to 1 (see [Table 7-56](#)).

Table 7-56. VRFB Rotation - DMA Settings

Rotation	Registers	GFX/VIDx ⁽¹⁾
0 degree	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA0 1 (2048 - iw) x ps + 1
90 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA90 + offset 1 (2048 - ih) x ps + 1
180 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA180 + offset 1 (2048 - iw) x ps + 1
270 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA270 + offset 1 (2048 - ih) x ps + 1

⁽¹⁾

- VBAx = virtual address of the chosen VRFB context and orientation
- iw = image width (width in pixels for RGB, width in pixels divided by 2 for YUV)
- ih = image height
- ps = pixel size in bytes (2 bytes per pixel for RGB, 4 bytes per pixel for YUV)
- Offset = see below

Figure 7-123 provides the offset values that must be added to the virtual base addresses for 90-degree, 180-degree, and 270-degree rotation. This offset is applicable only when the defined image size in the VRFB module is greater than the actual image size, because it must be a multiple of the page width and height. In the example discussed above, the image height was set to 256 lines, instead of 240, because the page height was 32 lines. This offset must be added to the virtual base addresses, because the VRFB module is not aware of the actual image size. Figure 7-123 illustrates why this occurs and how the offset is calculated.

Figure 7-123. Offset for VRFB Rotation

dss-099

Δ_{iw} = Image width delta between the actual image width and the programmed image width because of the page width

Δ_{ih} = Image height delta between the actual image height and the programmed image height because of the page height:

- Offset 90-degree: Δ_{ih} pixels = $\Delta_{ih} \times ps$ bytes
- Offset 180-degree: $2048 \times \Delta_{ih} + \Delta_{iw}$ pixels = $2048 \times \Delta_{ih} \times ps + \Delta_{iw} \times ps$ bytes
- Offset 270-degree: $2048 \times \Delta_{iw}$ pixels = $2048 \times \Delta_{iw} \times ps$ bytes

In the example given above, the delta in the image height is $256 - 240 = 16$ lines ($\Delta_{ih} = 16$), whereas the exact value of the width can be programmed ($\Delta_{iw} = 0$). In that case, the resulting offset values are:

- YUV:
 - Offset 90-degree: 16×4 bytes
 - Offset 180-degree: $2048 \times 16 \times 4$ bytes
 - Offset 270-degree: 0 bytes
- RGB:
 - Offset 90-degree: 16×2 bytes

- Offset 180-degree: 2048 x 16 x 2 bytes
- Offset 270-degree: 0 bytes

As with DMA rotation, mirroring along the vertical axis can be added on top of the rotation when using the VRFB. This mirroring is achieved by combining an appropriate VRFB rotation with a readout of the VRFB by the DSS DMA, going backwards from the last line to the first line of the rotated image. [Table 7-57](#) provides the DMA settings for VRFB rotation with mirroring.

Table 7-57. VRFB Rotation With Mirroring - DMA Settings

Rotation	Registers	GFX/VIDx ⁽¹⁾
0 degree	DSS.DISPC_xxx_BAj	VBA180 + 2048 x (ih - 1) x ps + offset
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-(2048 + iw) x ps + 1
90 degrees	DSS.DISPC_xxx_BAj	VBA270 + 2048 x (iw - 1) x ps + offset
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-(2048 + ih) x ps + 1
180 degrees	DSS.DISPC_xxx_BAj	VBA0 + 2048 x (ih - 1) x ps
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-(2048 + iw) x ps + 1
270 degrees	DSS.DISPC_xxx_BAj	VBA90 + 2048 x (iw - 1) x ps + offset
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-(2048 + ih) x ps + 1

⁽¹⁾

- VBAx = virtual address of the chosen VRFB context and orientation
- iw = image width (width in pixels for RGB, width in pixels divided by 2 for YUV)
- ih = image height
- ps = pixel size in bytes (2 bytes per pixel for RGB, 4 bytes per pixel for YUV)
- Offset = see below

Some offsets are required if there is a delta between the programmed image size in the VRFB and the actual image size. As shown in [Figure 7-124](#), this applies to 0-degree rotation with mirroring (using VBA 180-degree), 90-degree rotation with mirroring (VBA 270-degree), and 270-degree rotation with mirroring (VBA 90-degree). The offsets are calculated in this manner:

- Offset 0-degree (mirroring): $2048 \times \Delta ih + \Delta iw$ pixels = $2048 \times \Delta ih \times ps + \Delta iw \times ps$ bytes
- Offset 90-degree (mirroring): $2048 \times \Delta iw$ pixels = $2048 \times \Delta iw \times ps$ bytes
- Offset 270-degree (mirroring): Δih pixels = $\Delta ih \times ps$ bytes

Figure 7-124. Offset for VRFB Rotation With Mirroring

dss-101

7.5.3.4.4 Additional Configuration When Using YUV Format

The rotation flag (DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION bit , with n = 1 or 2) and the repeat flag (DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE) indicate the rotation to apply to the video-encoded pixels from the SDRAM and SRAM. The 2D addressing mode is used, but even when accessing the SDRAM buffer, some post-processing must be performed on the YUV 4:2:2 data depending on the rotation. These bits are set only when the video format is not RGB; otherwise, the bit field is reset to 0. Table 7-58 and Table 7-59 describe the configuration of these registers.

Table 7-58. Video Rotation Register Settings (YUV Only)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
0 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x0
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
90 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x1
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1
180 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x2
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0

Table 7-58. Video Rotation Register Settings (YUV Only) (continued)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
270 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x3
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

Table 7-59. Video Rotation With Mirroring Register Settings (YUV only)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
0 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x2
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
90 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x1
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1
180 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x0
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
270 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x3
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

NOTE: For YUV4:2:2 video-encoded pixels, the hardware must always fetch a 32-bit value from the system memory to generate a YUV4:4:4 value before YUV-to-RGB conversion.

- For 90- and 270-degree rotation, the missing chrominance samples for the odd pixels are generated by duplicating the chrominance samples of the previous even pixels.
- For 0- and 180-degree rotation, the missing chrominance samples for the odd pixels are generated by averaging the contiguous chrominance samples.

7.5.3.4.5 Video DMA Optimization

When a rotation of 90 or 270 degrees is required, the memory traffic can be reduced as described in [Section 7.4.2.8, Rotation](#).

1. Enable DMA optimization for the video pipelines VID1 and VID2 by applying the following settings to the DISPC:
 - (a) Enable DISPC DMA optimization by setting:
 - DISPC_VIDn_ATTRIBUTES[20] VIDDMAOPTIMIZATION = 1
 - DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE = 0
 - DISPC_VIDn_ATTRIBUTES[13:12] VIDROTATION = 0x1 or 0x3
 - (b) Configure DISPC for the following format:
 - DISPC_VIDn_ATTRIBUTES[4:1] VIDFORMAT = 0x6, 0xA, or 0xB
 - DISPC_VIDn_ATTRIBUTES[9] VIDCOLORCONVENABLE = 0x1 (only for YUV format)
 - (c) Configure DISPC scaler in 5-tap mode by setting:
 - DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS = 0x1
 - DISPC_VIDn_ATTRIBUTES[6:5] VIDRESIZEENABLE = 0x2 (vertical resize only, minimum setting) or 0x3 (vertical + horizontal resize)
 - DISPC_VIDn_ATTRIBUTES[22] VIDLINEBUFFERSPLIT = 0x1
2. Configure the rotation engine (VRFB) inside the SDRAM memory scheduler (SMS) as follows:
 - (a) Set the SMS-VRFB context pixel size to 32 bits by setting:
 - For RGB16 pixel format:
 - Writing context: SMS.SMS_ROT_CONTROLn[1:0] PS = 1
 - Reading context: SMS.SMS_ROT_CONTROLn[1:0] PS = 2

- For YUV pixel format:
 - Writing and reading context: SMS.SMS_ROT_CONTROLn[1:0] PS = 2
- (b) Set the SMS-VRFB context width to one half of the original width:
 - SMS.SMS_ROT_SIZEn[10:0] IMAGEWIDTH = Picture width in pixels /2 (because 2 pixels are present in each 32-bit container)

For more information about the VRFB module, see [Section 10.2.4.1.5, Rotation Engine](#), in [Section 10.2, SDRAM Controller \(SDRC\) Subsystem](#).

NOTE: When 5-tap mode is used, the scaling coefficients must be set even, if 1:1 scaling is required.

Matrix color space coefficients must be set for YUV format inside [DISPC_VIDn_CONV_COEF0](#) through the [DISPC_VIDn_CONV_COEF4](#) registers.

The width of the input original picture must be even (for YUV4:2:2 and RGB16 formats).

The DMA optimization feature must be used only for YUV and RGB16 formats when 90- or 270-degree rotation is required. In all other configurations, the [DISPC_VIDn_ATTRIBUTES\[20\]](#) VIDDMAOPTIMIZATION bit must be kept at reset value (0x0).

7.5.3.5 LCD-Specific Control Registers

The following registers define the LCD output configuration:

- DSS.[DISPC_CONTROL](#)
- DSS.[DISPC_CONFIG](#)
- DSS.[DISPC_DEFAULT_COLOR_m](#) (m=0)
- DSS.[DISPC_TRANS_COLOR_m](#) (m=0)
- DSS.[DISPC_TIMING_H](#)
- DSS.[DISPC_TIMING_V](#)
- DSS.[DISPC_POL_FREQ](#)
- DSS.[DISPC_DIVISOR](#)
- DSS.[DISPC_SIZE_LCD](#)
- DSS.[DISPC_DATA_CYCLEK](#)
- DSS.[DISPC_CPR_COEF_R](#), DSS.[DISPC_CPR_COEF_G](#), DSS.[DISPC_CPR_COEF_B](#)

Setting/resetting the DSS.[DISPC_CONTROL\[0\]](#) LCDENABLE bit enables/disables the LCD output. A valid configuration must be set before enabling the LCD output.

7.5.3.5.1 LCD Attributes

The following fields define the attributes of the panel connected to the display controller:

- Monochrome or color panel (the DSS.[DISPC_CONTROL\[2\]](#)MONOCOLOR bit)
- Passive Matrix or active Matrix panel (the DSS.[DISPC_CONTROL\[3\]](#) STNTFT bit)
- Color depth (the DSS.[DISPC_CONTROL\[9:8\]](#) TFTDATALINES bit field)
- Number of lines per panel (the DSS.[DISPC_SIZE_LCD\[26:16\]](#) LPP bit field)
- Number of pixels per line (the DSS.[DISPC_SIZE_LCD\[10:0\]](#) PPL bit field)
- 4- or 8-bit interface for Passive Matrix monochrome panel (the DSS.[DISPC_CONTROL\[4\]](#) M8B bit)

7.5.3.5.2 LCD Timings

The following bit fields define the timing generation of HSYNC/VSYNC:

- Horizontal front porch (the DSS.[DISPC_TIMING_H\[19:8\]](#) HFP bit field)

- Horizontal back porch (the DSS.DISPC_TIMING_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC_TIMING_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC_TIMING_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC_TIMING_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC_TIMING_V[7:0] VSW bit field)
- On/Off control of HSYNC/VSYNC pixel clock (the DSS.DISPC_POL_FREQ[17] ONOFF bit)
- Program HSYNC/VSYNC rise or fall (the DSS.DISPC_POL_FREQ[16] RF bit)
- Invert HSYNC (the DSS.DISPC_POL_FREQ[13] IHS bit)
- Invert VSYNC (the DSS.DISPC_POL_FREQ[12] IVS bit)
- HSYNC gated (the DSS.DISPC_CONFIG[6] HSYNCGATED bit)
- VSYNC gated (the DSS.DISPC_CONFIG[7] VSYNCGATED bit)

Table 7-60 describes the programming rules for LCD timing.

Table 7-60. Programming Rules

	No Downsampling	Downsampling H or V	Downsampling H + V
(HBP + HSW + HFP) * PCD	8	10	20

Figure 7-125 shows the timing values description in the case of an active matrix display.

Figure 7-125. Timing Values Description (Active Matrix Display)

dss-102

The following bit fields define the timing generation of ac-bias (output enable in active matrix mode):

- Invert output enable (DSS.DISPC_POL_FREQ[15] IEO bit)
- ac-bias pin frequency (DSS.DISPC_POL_FREQ[7:0] ACB bit field)
- ac-bias pin transitions per interrupt (DSS.DISPC_POL_FREQ[11:8] ACBI bit field)
- ac-bias gated (DSS.DISPC_CONFIG[8] ACBIASGATED)

The following bit fields define the timing generation of the pixel clock:

- Pixel clock divisor (DSS.DISPC_DIVISOR[7:0] PCD bit field)
- Invert pixel clock (DSS.DISPC_POL_FREQ[14] IPC bit)

- Pixel clock gated (DSS.DISPC_CONFIG[5] PIXELCLOCKGATED bit)

The 8-bit pixel clock divider (the DSS.DISPC_DIVISOR[7:0] PCD bit field) selects the pixel clock frequency. This bit field generates a range of pixel clock frequencies from LC/1 to LC/255, where LC is the logic clock from the divided functional clock of the display controller by the DSS.DISPC_DIVISOR[23:16] LCD bit field.

The pixel clock is defined by the following equation:

$$\text{Pixel Clock} = (\text{FunctionalClock}/\text{LCD}[7:0])/\text{PCD}[7:0]$$

Table 7-61 through **Table 7-64** show the pixel clock frequency limitations depending the panel type (active or passive matrix) and the mode (color or monochrome).

Table 7-61. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Active Matrix Display

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	2 (1) ⁽¹⁾	2 (1)	2	3	4
	Up	2 (1)	2 (1)	2	3	4
	1:1 - 1:2	3-tap	2	2	4	6
		5-tap	PCDmin	PCDmin	PCDmin	PCDmin
	1:2 - 1:4		PCDmin	PCDmin	PCDmin	PCDmin

⁽¹⁾ The PCD value can be 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the pixel clock.

Table 7-62. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Passive Matrix Display - Mono4

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	4	4	8	12	16
	Up	4	4	8	12	16
	1:1 - 1:2	3-tap	8	8	16	24
		5-tap	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin
	1:2 - 1:4		4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin

Table 7-63. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Passive Matrix Display - Mono8

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	8	8	16	24	32
	Up	8	8	16	24	32
	1:1 - 1:2	3-tap	16	16	32	48
		5-tap	8xPCDmin	8xPCDmin	8xPCDmin	8xPCDmin
	1:2 - 1:4		8xPCDmin	8xPCDmin	8xPCDmin	8xPCDmin

Table 7-64. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Passive Matrix Display - Color

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	3	3	6	9	12
	Up	3	3	6	9	12
	1:1 - 1:2	3-tap	6	12	18	24
		5-tap	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin
	1:2 - 1:4		3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin

NOTE: In case of RGB24 format, [Figure 7-126](#) is still valid, except the PCDmin values which must be multiplied by two.

The PCDmin for vertical downsampling only is defined by the following equations:

Figure 7-126. PCDmin Formulas (V Down-Sampling Only)

$$h_ratio = \frac{DISPC_SIZE_LCD[10:0]PLL}{DISPC_VIDn_SIZE[10:0]VIDZSIZEX}$$

$$v_ratio = \frac{DISPC_VIDn_PICTURE_SIZE[10:0]VIDORGSIZEY}{DISPC_VIDn_SIZE[10:0]VIDSIZEY}$$

$$PCD\ min = \frac{v_ratio}{2 \times h_ratio} \quad 1 < v_ratio \leq 2$$

$$PCD\ min = \max\left(\frac{v_ratio}{2 \times h_ratio}, \frac{v_ratio - 2}{2 \times (h_ratio - 1)}\right) \quad 2 < v_ratio \leq 4$$

dss-E103

The PCDmin for horizontal downsampling only is defined by the following formula:

While downsampling by n, $PCDmin = n$

For H+V downsampling, the formula is the following:

$PCDmin = \max(PCODEmin\ H\ only, PCDmin\ V\ only)$ as defined above

The refresh rate depends on the following parameters:

- Horizontal front porch (the DSS.[DISPC_TIMING_H](#)[19:8] HFP bit field)
- Horizontal back porch (the DSS.[DISPC_TIMING_H](#)[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.[DISPC_TIMING_H](#)[7:0] HSW bit field)
- Vertical front porch (the DSS.[DISPC_TIMING_V](#)[19:8] VFP bit field)
- Vertical back porch (the DSS.[DISPC_TIMING_V](#)[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.[DISPC_TIMING_V](#)[7:0] VSW bit field)
- Number of lines per panel (the DSS.[DISPC_SIZE_LCD](#)[26:16] LPP bit field)
- Number of pixels per line (the DSS.[DISPC_SIZE_LCD](#)[10:0] PPL bit field)
- 4- or 8-bit interface for the passive matrix monochrome panel (the DSS.[DISPC_CONTROL](#)[4] M8B bit)

The following bit fields define the behavior of the internal blocks:

- Spatial/temporal dithering logic enabled (DSS.[DISPC_CONTROL](#)[7] SPATIALTEMPORALDITHERENABLE bit)
- Spatial/temporal dithering logic number of frames (DSS.[DISPC_CONTROL](#)[31:30] SPATIALTEMPORALDITHERFRAMES bit field). The default value of this bit field at reset time is 0x0, which is 1 frame only (spatial processing without temporal dithering). The possible values are 0x0 (one frame), 0x1 (two frames), and 0x2 (four frames). The number of frames is initialized before enabling the spatial/temporal dithering unit. The software must not change this bit field value while the spatial/temporal unit is enabled.

The following bit field defines the clock gating strategy:

- In active matrix mode, the pixel clock is always gated or only when valid data are present (the DSS.[DISPC_CONFIG](#)[0] PIXELGATED bit).

7.5.3.5.3 LCD Overlay

The following bit fields define the overlay attributes of the LCD output:

- Transparency color key (the DSS.[DISPC_TRANS_COLOR0i](#) register (i = 0))
- Transparency color key enable (the DSS.[DISPC_CONFIG](#)[10] TCKLCDENABLE bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.[DISPC_CONFIG](#)[11] TCKLCDSELECTION bit)

- The default solid background color is defined in the DSS.[DISPC_DEFAULT_COLOR_m](#)[23:0] DEFAULTCOLOR bit field (i=0).
- Alpha blender Enable (DSS.[DISPC_CONFIG](#)[18] LCDALPHABLENDERENABLE)
- Global alpha blending values (DSS.[DISPC_GLOBAL_ALPHA](#)[23:16] VID2GLOBALALPHA and DSS.[DISPC_GLOBAL_ALPHA](#)[7:0] GFXGLOBALALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

NOTE: The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

NOTE: When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

When all of these fields are set to the appropriate values, set the DSS.[DISPC_CONTROL](#)[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.[DISPC_CONTROL](#)[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.[DISPC_CONTROL](#)[0] LCDENABLE bit will be set to 1.

7.5.3.5.4 LCD TDM

The following fields define the multiple cycle output configuration:

- First cycle (the DSS.[DISPC_DATA_CYCLEk](#) (k=0) register)
- Second cycle (the DSS.[DISPC_DATA_CYCLEk](#) (k=1) register)
- Third cycle (the DSS.[DISPC_DATA_CYCLEk](#) (k=2) register)
- Enable (the DSS.[DISPC_CONTROL](#)[20] TDMENABLE bit)
- Parallel mode (the DSS.[DISPC_CONTROL](#)[22:21] TDMPARALLELMODE field)
- Cycle format (the DSS.[DISPC_CONTROL](#)[24:23] TDMCYCLEFORMAT field)
- Unused bits (the DSS.[DISPC_CONTROL](#)[26:25] TDMUNUSEDBITS field)

When all of these bit fields are set to the appropriate values, set the DSS.[DISPC_CONTROL](#)[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.[DISPC_CONTROL](#)[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.[DISPC_CONTROL](#)[0] LCDENABLE bit will be set to 1.

7.5.3.5.5 LCD Spatial/Temporal Dithering

The following bit fields define the LCD spatial/temporal dithering configuration:

- Number of frames (the DSS.[DISPC_CONTROL](#)[31:30] SPATIALTEMPORALDITHERINGFRAMES bit field) with:
 - 0x0 Spatial only (default value)
 - 0x1 Spatial + Temporal over two frames
 - 0x2 Spatial + Temporal over four frames
 - 0x3 Reserved
- Enable (the DSS.[DISPC_CONTROL](#)[7] SPATIALTEMPORALDITHERENABLE bit)
 - 0x0 Disabled (default value)
 - 0x1 Enabled

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

7.5.3.5.6 LCD Color Phase Rotation

The following bit fields define the color phase rotation configuration:

- Enable (the DSS.DISPC_CONFIG[15] CPR bit)
 - 0x0 Disabled (default value)
 - 0x1 Enabled
- Red 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_R register)
- Green 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_G register)
- Blue 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_B register)

The programmable color phase rotation block for the LCD output has nine 10-bit coefficients defined in the DSS.DISPC_CPR_COEF_R, DSS.DISPC_CPR_COEF_G, and DSS.DISPC_CPR_COEF_B, as described in Figure 7-127 through Figure 7-130.

Figure 7-127. Color Phase Rotation Matrix

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dss-E105

Figure 7-128. Color Phase Rotation Matrix (R Component Only)

$$R_{out} = \frac{1}{256} * (RR * R_{in} + RG * G_{in} + RB * B_{in})$$

dss-E106

Figure 7-129. Color Phase Rotation Matrix (G Component Only)

$$G_{out} = \frac{1}{256} * (GR * R_{in} + GG * G_{in} + GB * B_{in})$$

dss-E107

Figure 7-130. Color Phase Rotation Matrix (B Component Only)

$$B_{out} = \frac{1}{256} * (BR * R_{in} + BG * G_{in} + BB * B_{in})$$

dss-E104

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

7.5.3.5.6.1 Color Phase Rotation - Diagonal Matrix

The Color Phase Rotation feature is useful when using an LCD backlight that is not white. By using a correct configuration of the R, G and B coefficients of CPR, the color bias of the screen can be corrected. The following paragraphs give an example of configuration of the CPR feature.

The easiest example of CPR configuration is a diagonal matrix. This way, the output colors depends on one input color only. [Figure 7-131](#) gives the example of a diagonal matrix and the corresponding equation of the output components.

Figure 7-131. Diagonal Matrix Configuration

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & 0 & 0 \\ 0 & GG & 0 \\ 0 & 0 & BB \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix}$$

$$\rightarrow Rout = \frac{1}{256} * (RR * Rin)$$

$$\rightarrow Gout = \frac{1}{256} * (GG * Gin)$$

$$\rightarrow Bout = \frac{1}{256} * (BB * Bin)$$

dss-200

According to these 3 new equations, each output component only depends on the corresponding input color. The coefficients can easily be used to reduce the impact of a non-white backlight.

Let's take the example of a "blue" backlight. In this case, users have the feeling that a blue film has been added on the screen, and then each color seems to be "too much blue". The goal is then to reduce the "Blue" component and to keep the "Red" and "Green" ones unchanged. The following matrix can be used for a reduction by a half of the blue component. [Figure 7-132](#) gives the corresponding matrix and equations for each component.

Figure 7-132. Example - Diagonal Matrix Configuration

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ 0 & 0 & 128 \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix}$$

$$\rightarrow Rout = \frac{1}{256} * (256 * Rin) \Rightarrow Rout = Rin$$

$$\rightarrow Gout = \frac{1}{256} * (256 * Gin) \Rightarrow Gout = Gin$$

$$\rightarrow Bout = \frac{1}{256} * (128 * Bin) \Rightarrow Bout = 0.5 * Bin$$

dss-201

[Figure 7-133](#) shows the result of an image on a "blue" backlight screen with and without CPR.

Figure 7-133. Image With and Without CPR (Diagonal Matrix)

dss-202

A drawback of this diagonal matrix is that the color reduction is linear. The contrast is then different from the initial image. It is then necessary to use the 6 other coefficients of the CPR matrix to better correct a non-white backlight. The goal is to find the correct coefficients that remove the color offset added by the non-white backlight.

7.5.3.5.6.2 Color Phase Rotation - Standard Matrix

In the following example, the LCD backlight adds an offset of 128 (B_offset) to the Blue component. [Figure 7-134](#) shows an example of matrix that reduces the offset of the screen, the corresponding equations and the resulting output colors.

Figure 7-134. Example - Image With and Without CPR (Standard Matrix)

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ -129 & -129 & 370 \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix}$$

$$\rightarrow Rout = \frac{1}{256} * (256 * Rin)$$

$$\rightarrow Gout = \frac{1}{256} * (256 * Gin)$$

$$\rightarrow Bout = \frac{1}{256} * (-129 * Rin + -129 * Gin + 370 * Bin) + B_offset$$

dss-203

This CPR matrix gives inputs and outputs very close. However, black cannot be corrected because of it's zero-components. No matter which coefficients are used in the matrix, the result will always be equal to the offset added by the LCD backlight.

7.5.3.6 TV Set-Specific Control Registers

The following registers define the digital output configuration:

- DSS.[DISPC_CONTROL](#)
- DSS.[DISPC_CONFIG](#)
- DSS.[DISPC_DEFAULT_COLOR_m](#) (m=1)
- DSS.[DISPC_TRANS_COLOR_m](#) (m=1)
- DSS.[DISPC_SIZE_DIG](#)

The digital output is enabled/disabled by setting/resetting the DSS.[DISPC_CONTROL\[1\]](#) DIGITALENABLE bit. A valid configuration must be set before the digital output can be enabled.

Perform the initialization sequence as follows:

1. Initialize the video encoder and the display controller configuration registers.
2. Set the DSS.[DISPC_CONTROL\[6\]](#) GODIGITAL bit and the DSS.[DISPC_CONTROL\[1\]](#) DIGITALENABLE bit to 1.
3. Wait for the first VSYNC pulse signal.
4. Clear the SYNCLOSTDIGITAL interrupt by setting the DSS.[DISPC_IRQSTATUS\[15\]](#) SYNCLOSTDIGITAL bit to 1.
5. Enable the SYNCLOSTDIGITAL interrupt by setting the DSS.[DISPC_IRQENABLE\[15\]](#)

SYNCLOSTDIGITAL bit to 1.

7.5.3.6.1 Digital Timings

The following bit fields define the timing information:

- Data hold time (the DSS.DISPC_CONTROL[19:17] HT bit field)
- Logic clock divisor (the DSS.DISPC_DIVISOR[23:16] LCD bit field)

The 8-bit pixel clock divider (DSS.DISPC_DIVISOR[23:16]) bit field is used to select the logic clock frequency. The LCD generates a range of pixel clock frequencies from FCK/1 to FCK/255, where FCK is the input functional clock of the display controller.

7.5.3.6.2 Digital Frame/Field Size

The following bit fields define the field size (frame if progressive mode):

- Number of lines per panel (the DSS.DISPC_SIZE_DIG[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC_SIZE_DIG[10:0] PPL bit field)

7.5.3.6.3 Digital Overlay

The following bit fields define the overlay attributes of the digital output:

- Transparency color key (the DSS.DISPC_TRANS_COLOR_m register (m=1))
- Transparency color key enable (the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit)
- The default solid background color is defined in the DSS.DISPC_DEFAULT_COLOR_m[23:0] DEFAULTCOLOR bit field (i=1).
- Alpha blender Enable (DSS.DISPC_CONFIG[19] TVALPHABLENDERENABLE)
- Global alpha blending values (DSS.DISPC_GLOBAL_ALPHA[23:16] VID2GLOBALALPHA and DSS.DISPC_GLOBAL_ALPHA[7:0] GFXGLOBALALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

NOTE: The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

NOTE: When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

When this bit field is set to the appropriate values, set the DSS.DISPC_CONTROL[6] GODIGITAL bit to indicate that all shadow registers of the pipelines connected to the digital output are latched by the hardware (only if the DSS.DISPC_CONTROL[1] DIGITALENABLE bit is already set to 1). If the digital output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[1] DIGITALENABLE bit will be set to 1.

7.5.4 DSI Protocol Engine Basic Programming Model

This section describes the programming model of the DSI protocol engine.

7.5.4.1 Software Reset

The DSI protocol engine can be reset by software. This reset can be done for debug purposes or after a

protocol error and has the same effect as the hardware reset. The DSI protocol engine can be reset by setting the DSS.DSI_SYSCONFIG[1] SOFT_RESET bit to 1. The software can monitor the DSS.DSI_SYSSTATUS[0] RESET_DONE status bit to wait for the completion of the reset procedure. If after 5 reads, the DSS.DSI_SYSSTATUS[0] RESET_DONE status bit still returns 0, it can be assumed that an error occurred during the reset stage.

NOTE: This software reset is optional as an hardware reset is always performed on the DSI protocol engine at device reset.

7.5.4.2 Power Management

The power management behavior of the DSI protocol engine is controlled by the DSS.DSI_SYSCONFIG register. This register completely controls the way the module interferes with the PRCM module. The DSS.DSI_SYSCONFIG[0] AUTO_IDLE bit should be set to 1 (default value) to enable automatic clock gating in the module.

7.5.4.3 Interrupts

There is a single interrupt request: DSI_IRQ. This interrupt line is merged with another interrupt line from the DISPC_IRQ in a single interrupt request DSS_IRQ. The DSI_IRQ events are generated only for the enabled VC(s). Two registers are used to enable and monitor the DSI interrupt events:

- DSS.DSI_IRQENABLE register: This register indicates the enabled/disabled event for the VCs. Each event for the VC is configured in the DSS.DSI_VCn_IRQENABLE register dedicated to the VC number. In addition, it includes one bit for the enable of error reporting for the complex I/O: Error signaling from the complex I/O: The interrupt is triggered when any error is received from the complex I/O (ErrSyncEsc[4:0], ErrEsc[4:0] (edge trigger interrupt), ErrControl[4:0] and ErrContentionLP0[4:0], ErrContentionLP1[4:0] from the complex I/O).
- DSS.DSI_IRQSTATUS register : The register DSI_IRQSTATUS flags which VC(s) is/have generated an interrupt. Based on the VC number, the register DSI_VCn_IRQSTATUS indicates the event generating the interrupt. In addition, it includes one bit for the status of error reporting for the complex I/O.

7.5.4.4 Global Register Controls

Prior to receive data from the DSI complex I/O, the DSI_PHY_SCP registers in the DSI complex I/O must be configured. Refer to [Section 7.5.6](#) for more details. [Table 7-65](#) details the register access width limitations for all the DSI modules.

Table 7-65. Register Access Width Limitations

Register Name	Register Access Width
All DSI complex I/O register (DSI_PHY_SCP)	32-bit only
All DSI PLL control module registers	32-bit only
DSI_VCn_LONG_PACKET_HEADER	32-bit only
DSI_VCn_SHORT_PACKET_HEADER	32-bit only
DSI_VCn_LONG_PACKET_PAYLOAD	16-bit, 32-bit
All others DSI protocol engine registers	8-bit, 16-bit and 32-bit

CAUTION

In case of different access width detailed in [Table 7-65](#), an OCP error is generated in response to the write using SResp=ERR.

The DSI protocol engine is globally controlled by the DSS.DSI_CTRL register. The interface to the

complex I/O is enabled by setting the DSS.[DSI_CTRL\[0\]](#) IF_EN bit. When the interface is disabled, it is possible to provide data to the TX FIFO and read pending data in the RX FIFO. When the DSS.[DSI_CTRL\[0\]](#) IF_EN bit is set to 1, the pending packets should be sent to the DSI complex I/O, the data transfer from the video port should be ignored only when received the next Vertical Sync Event which is received but not send to the DSI complex I/O.

When the DSS.[DSI_CTRL\[0\]](#) IF_EN bit is reset by software, the hardware should finish the transfer of the pending data in the TX FIFO and wait for response if BTA has been sent (Protocol engine is receive mode), then the hardware resets the DSS.[DSI_CTRL\[0\]](#) IF_EN bit. When using the video mode, the VC associated with the video port should be enabled prior to enable the interface according to the following sequence:

- DSS.[DSI_CTRL\[0\]](#) IF_EN bit is equal to 0
- Enable the VC associated with video mode by setting the DSS.[DSI_VCn_CTRL\[0\]](#) VC_EN
- Set the DSS.[DSI_CTRL\[0\]](#) IF_EN bit to 1

7.5.4.5 Virtual Channels

There is one set of registers for each VC. The attributes of the VC define the following characteristics:

- Transfer mode (DSS.[DSI_VCn_CTRL\[4\]](#) MODE bit):
 - Video mode
 - Command mode
- Data type
- Source (DSS.[DSI_VCn_CTRL\[1\]](#) SOURCE bit)
 - Video port
 - L4 interconnect port
- HS or LP forward transmission
- Automatic bus turn-around generation
 - Short packets (DSS.[DSI_VCn_CTRL\[2\]](#) BTA_SHORT_EN bit)
 - Long packets (DSS.[DSI_VCn_CTRL\[3\]](#) BTA_LONG_EN bit)
- DMA request configurations for RX and TX
 - DMA request number (DSS.[DSI_VCn_CTRL\[29:27\]](#) DMA_RX_REQ_NB bit field for RX FIFO and DSS.[DSI_VCn_CTRL\[23:21\]](#) DMA_TX_REQ_NB bit field for TX FIFO)
 - DMA threshold (DSS.[DSI_VCn_CTRL\[26:24\]](#) DMA_RX_THRESHOLD bit field for RX FIFO and DSS.[DSI_VCn_CTRL\[19:17\]](#) DMA_TX_THRESHOLD bit field for TX FIFO)
- Mode speed (DSS.[DSI_VCn_CTRL\[9\]](#) MODE_SPEED bit)
- ECC transmission (DSS.[DSI_VCn_CTRL\[8\]](#) ECC_TX_EN bit)
- CS transmission (DSS.[DSI_VCn_CTRL\[7\]](#) CS_TX_EN bit)

The VC ID not calculated by the DSI module but provided while writing into the registers [DSI_VCn_SHORT_PACKET_HEADER](#) and [DSI_VCn_LONG_PACKET_HEADER](#).

7.5.4.6 Packets

The DSS.[DSI_VCn_SHORT_PACKET_HEADER](#) register is used to send only short packets (ECC can be calculated by hardware or by software user for debug purpose). The register is not used for video mode data since the short packets are generated by the hardware using the following information:

- synchronization events received on the video port (assertion/deassertion of the HSYNC and VSYNC input signals)
- DSS.[DSI_CTRL\[18\]](#) VP_HSYNC_END
- DSS.[DSI_CTRL\[17\]](#) VP_HSYNC_START
- DSS.[DSI_CTRL\[16\]](#) VP_VSYNC_END
- DSS.[DSI_CTRL\[15\]](#) VP_VSYNC_START
- DSS.[DSI_CTRL\[10\]](#) VP_HSYNC_POL

- DSS.DSI_CTRL[11] VP_VSYNC_POL
- DSS.DSI_VCn_CTRL[1] SOURCE

The DSS.DSI_VCn_LONG_PACKET_HEADER register is used to provide header for long packets (ECC is always calculated by hardware). The register is used for video mode and command mode. If the video mode is enabled for the VC, it is not possible to transfer concurrently (interleaved in a frame) data using long packets received on the video port and on the L4 interconnect port since the DSS.DSI_VCn_LONG_PACKET_HEADER register is used by the video mode. The register can be unprogrammed by users to send long packets received on the L4 interconnect port only when software users know that there is no expected data on the video port. The software should correctly program the register to send sequentially long packets in video and command modes.

The DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is used to provide payload data for long packets (Check-sum is calculated by hardware when DSS.DSI_VCn_CTRL[7] CS_TX_EN is set to 1 otherwise the value 0x00 is used). The register is not used in video mode since payload data are provided by the video port. The software should ensure that the following sequence for write accesses to the header and payload registers (DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_LONG_PACKET_PAYLOAD, respectively) is followed:

- A long packet header value with WC=0 written in DSS.DSI_VCn_LONG_PACKET_HEADER register can be followed by any access.
- A long packet header value with WC0 written in DSS.DSI_VCn_LONG_PACKET_HEADER register should be followed by one or more writes to the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register defined by the WC value before writing again to the same DSS.DSI_VCn_LONG_PACKET_HEADER register.

CAUTION

If this sequence is not followed, no error is generated. The access to other DSI registers during this sequence is allowed.

7.5.4.7 DSI Complex I/O

Prior to send/receive any data from the complex I/O, the DSI complex I/O timings should be set according to the display module timings. The DSI complex I/O pads must also be configured first. See [Section 7.5.6, DSI Complex I/O Basic Programming Model](#).

7.5.4.8 Video Mode

The DSS.DSI_VM_TIMING1, DSS.DSI_VM_TIMING2, DSS.DSI_VM_TIMING3, DSS.DSI_VM_TIMING4, DSS.DSI_VM_TIMING5, DSS.DSI_VM_TIMING6, and DSS.DSI_VM_TIMING7 registers define the timings of the video mode.

The DSS.DSI_CTRL[20] BLANKING_MODE bit defines if the long blanking packets or LPS state are used during the blanking periods (except HFP, HBP, HSA defined by other bits) when there is no pending data in TX FIFO ready to be sent. The software should ensure that there is no data in the TX FIFO, no BTA, no RESET trigger sent, and the DSS.DSI_VCn_CTRL[9] MODE_SPEED bit is set to 1 (High-Speed mode) to keep the video mode transfer in HS mode during blanking periods (except for the last blanking period since it is required to go LPS at least once per frame).

The DSS.DSI_CTRL[21] HFP_BLANKING_MODE, DSS.DSI_CTRL[22] HBP_BLANKING_MODE and DSS.DSI_CTRL[23] HSA_BLANKING_MODE define if these blanking can send packets from the TX FIFO or should be kept in HS mode using only long blanking packets.

To ensure that the writes to the register DSS.DSI_VCn_LONG_PACKET_HEADER are correctly handled as header information for video mode long packets, the following registers should be programmed:

- DSS.DSI_VCn_CTRL[0] VC_EN bit set to 1
- DSS.DSI_VCn_CTRL[4] MODE bit set to 1
- DSS.DSI_VCn_LONG_PACKET_HEADER register access
- DSS.DSI_VCn_CTRL[0] VC_EN bit set to 1

NOTE: The DSS.DSI_VCn_CTRL[1] SOURCE and DSS.DSI_VCn_CTRL[9] MODE_SPEED bits are ignored by hardware when the video mode is selected (DSS.DSI_VCn_CTRL[4] MODE bit set to 1)

The interrupt events SYNC_LOST_IRQ and RESYNCHRONIZATION_IRQ indicates if the DSI protocol engine has not been able to resynchronize the video port timing to its own timing base or if it has been done. The RESYNCHRONIZATION_IRQ indicates software users that the video port works but the configuration of the timings for the display controller (DISPC) and for DSI Protocol engine may need to be modified to avoid the resynchronization to occur. The SYNC_LOST_IRQ and RESYNCHRONIZATION_IRQ events can be respectively monitored in DSS.DSI_IRQSTATUS[18] SYNC_LOST_IRQ and DSS.DSI_IRQSTATUS[5] RESYNCHRONIZATION_IRQ status bits.

The DSS.DSI_VM_TIMING2[27:24] WINDOW_SYNC bit field defines the synchronization period. The recommended value is 0x4 based on the implementation of the resynchronization scheme.

7.5.4.9 Video Port Data Bus

The DSS.DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field is used to determine the width of the data bus on the video port. The supported formats are 16-bit, 18-bit and 24-bits.

7.5.4.10 Command Mode

7.5.4.10.1 Command Mode TX FIFO

The single TX FIFO is used on the L4 interconnect port to receive the data to be sent to the peripheral. The configuration of the FIFO for a specific VC should be done only when the VC is disabled.

Users should not enable the VC if there is still some pending data in the TX FIFO for the corresponding space allocated for the VC from previous active period. When the VC space in the TX FIFO is empty, the VC can be enabled.

For each VC, two dedicated DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers are used to provide data for long packets. The register DSS.DSI_VCn_SHORT_PACKET_HEADER is used to provide data for short packets (32-bit long).

For each long packet, the DSS.DSI_VCn_LONG_PACKET_HEADER register should be written first and then the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The only exception is when the word count defined in the header is equal to 0. In that case, it is not required to write into the payload register. For consecutive long packets, the header should be written into the DSS.DSI_VCn_LONG_PACKET_HEADER register even if the value remains the same.

The TX FIFO stores all the pending bytes to be sent to the peripheral(s). Multiple receivers can be addressed using the VC capability.

The 32-bit write requests only for each VC to the TX FIFO should be kept in order while sending the data to the DSI_PHY inside the VC requests. The only exception is in the case of last 32-bit write for the last bytes of the payload data since it could be 1, 2, 3, or 4 bytes.

Also in case the last transfer is a 32-bit write but the number of valid bytes is 1, 2, or 3 only (calculated using the header word count and the number of bytes are received for the payload), the hardware should store the 32-bit value into the TX FIFO but the invalid bytes are not sent, and are discarded.

When the word count defined in DSS.DSI_VCn_LONG_PACKET_HEADER register is not a multiple of the request threshold value defined in DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field, 32-bit requests and/or bytes should be discarded by the hardware to store in FIFO only the exact number of valid bytes.

The DSI protocol module should be able to determine if the bytes in the TX FIFO correspond to a short or long packet without decoder the DT field. When the bytes are written into the DSS.DSI_VCn_SHORT_PACKET_HEADER, DSS.DSI_VCn_LONG_PACKET_HEADER, and DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers, the hardware should store the information concerning long or short packet. A 1-bit flag should be used for each entry of the TX FIFO.

When the VC is disabled, the remaining bytes in the FIFO should be sent to the DSI link. The start event to send data to the DSI link one of the following events:

- All bytes have been received in the FIFO (header + payload).
- The space of the FIFO allocated for the VC is full.
- The space of the FIFO allocated for the VC is not enough to request more data using DMA request (threshold value bigger than space left in the TX FIFO for the VC).

NOTE: In case the video mode is active, the blanking period should be large enough to allow the transfer of the packet(s).

Sequential arbitration must be set (TX_FIFO_ARBITRATION[3] [DSI_CTRL](#) bit = 0x1) if only one VC is used to send multiple packets during the same blanking period.

When consecutive packets should be sent in HS mode, to ensure that there is no LP transition between them at least one of the following condition should be valid:

- Packets from the same VC
- Short packets or long packets with a payload size multiple of 4 bytes

To flush the FIFO (discard of the data) for some pending bytes, the software should change the allocated size of the chuck FIFO by:

- First disabling the VC resetting DSS.[DSI_VCn_CTRL](#)[0] VC_EN bit to 0
- Second change the size of the space of FIFO to 0 by writing the DSS.[DSI_TX_FIFO_VC_SIZE](#) VCn_FIFO_SIZE (n is the VC value between 0 and 3)

If there is an on-going packet transfer from the TX FIFO to DSI_PHY, the flush of the FIFO should stop immediately the transfer. Because the FIFO is accessible to users, it must ensure that there are no bytes left in the FIFO before starting the flush operation. But it can be required in dead-lock situation to flush the FIFO even if there are still bytes in the FIFO, in that case, the software should also take care of having a known state of the whole DSI protocol engine module (software reset may be required) To start of new transfer through the TX FIFO.

Users can check that there is no pending request before changing the size of the allocated FIFO for the VC by reading the relevant DSS.[DSI_VCn_CTRL](#)[15] VC_BUSY bit or by using the interrupt

PACKET_SENT_IRQ: All the packets have been sent by counting the transferred requests to the L4 interconnect port and the number of requests sent to the DSI complex I/O. This interrupt can be monitoring by reading the DSS.[DSI_VCn_IRQSTATUS](#)[2] PACKET_SENT_IRQ status bit.

The DSS.[DSI_CTRL](#)[3] TX_FIFO_ARBITRATION bit defines if the arbitration scheme is:

- Round-robin between enabled VCs with pending ready requests (pending ready request means that all bytes for the packets are in the FIFO or the space of the FIFO for the VC is full) starting from the VC which has the least VC ID number.
- Sequential: All the pending ready requests for one VC are sent before moving to another VC. The condition of "space of the FIFO is full" should be evaluated after the end of each packet.

If users want to use sequential arbitration for all requests for all channels, a single VC should be used. (the VC ID defined in the header provided to the hardware using either the DSS.[DSI_VCn_LONG_PACKET_HEADER](#) or DSS.[DSI_VCn_SHORT_PACKET_HEADER](#) register is not used and not modified by the DSI protocol engine).

The register DSS.[DSI_TX_FIFO_VC_SIZE](#) defines the allocated number of 33-bit values for each VC in the TX FIFO and the start address for each VC. The size of the space allocated in the TX FIFO defined by DSS.[DSI_TX_FIFO_VC_SIZE](#) VCn_FIFO_SIZE (n corresponds to the VC number n) bit fields should be a multiple of the threshold defined in DSS.[DSI_VCn_CTRL](#)[19:17] DMA_TX_THRESHOLD bit field. Only the enabled VCs should be taken into account. To change the size of the space of the memory allocated for a specific VC, the VC should be disabled by setting the DSS.[DSI_VCn_CTRL](#)[0] VC_EN bit to 0. The whole FIFO may not be used by all the VCs at a given time since a VC can be disabled to change one or multiple parameters. Software users are responsible for correctly configuring the start address and the size for each VC.

[Table 7-66](#) indicates the corresponding values for the size of the space allocated in the FIFO.

Table 7-66. Virtual Channel TX FIFO Size Values

DSI_TX_FIFO_VC_SIZE.VCn_FIFO_SIZE[n = 0, 3]	Space Size (up to the size of the FIFO)
0	0 x 33 bits
1	32 x 33 bits
2	64 x 33 bits
3	96 x 33 bits
4	128 x 33 bits

The total size of TX FIFO is 128*33 bits. Therefore, the sum of all virtual channel FIFO allocation cannot exceed 128*33 bits.

Table 7-67 indicates the start address of the space in the FIFO.

Table 7-67. Virtual Channel TX FIFO Start Address

DSI_TX_FIFO_VC_SIZE.VCx_FIFO_ADD[x = 0, 2]	Start Address
0	0
1	32
2	64
3	96
4	128

CAUTION

There must be no overlap of different VCs spaces.

When the TX FIFO is full:

- the overflow interrupt (FIFO_TX_OVF_IRQ) is generated. To monitor this interrupt request, users can read the DSS.[DSI_VCn IRQSTATUS\[3\]](#) FIFO_TX_OVF_IRQ status bit.
- there is no L4 interconnect error generated
- the commands are accepted but the data are not written into the FIFO

To ensure that all writes are correctly stored in the TX FIFO, the FIFO should not be full. The software must read the room in the space allocated for the VC in the TX FIFO by reading the DSS.[DSI_TX_FIFO_VC_EMPTINESS](#) register. In case there is no space allocated in the TX FIFO for the VC, the DSS.[DSI_TX_FIFO_VC_EMPTINESS](#) register indicates a value of 0 for the VC space emptiness.

When waiting to receive the first VSYNC event on the video port to start the video mode on DSI link no command data from TX FIFO should be sent on the interface. It is required to ensure that when receiving the VSYNC event, there is no on-going command mode transfer that could delay the start of video mode on the DSI link.

7.5.4.10.2 Command Mode RX FIFO

The RX FIFO is used to store the data received from the DSI complex I/O. The data are always packed in the RX FIFO (single or multiple packets receiving during a single or multiple BTA periods).

The read requests access to corresponding VC locations to transfer data for a specific VC. The logic managing the FIFO must be able to extract 32-bit values in-order for a specific VC upon read requests. The byte enable of the read access is ignored. Each read returns one 32-bit value from the RX FIFO. If the application accesses the RX FIFO should extract always 32-bit values. Only in the case of 1, 2, or 3 bytes are remaining in the RX FIFO.

The read requests (single or burst) can be less, equal or greater than the packet size. If the packet size is smaller than the read request, the following packet(s) is also transferred. If the packet size is longer than the read request, only part of the packet is transfer. In that case, the logic should keep the VC information to provide the rest of the data during the next read request(s).

The register DSS.[DSI_RX_FIFO_VC_SIZE](#) defines the allocated number of 33-bit values for each VC in the RX FIFO and the start address for each VC. Only the enabled VCs should be taken into account. To change the size of the space of the memory allocated for a specific VC, the VC should be disabled by resetting the DSS.[DSI_VCn_CTRL\[0\]](#) VC_EN bit to 0. The whole FIFO may not be used by the entire VC at a given time since a VC can be disabled to change one or multiple parameters. Software users are responsible for correctly configuring the start address and the size for each VC.

[Table 7-68](#) indicates the corresponding values for the size of the space allocated in the FIFO:

Table 7-68. Virtual Channel RX FIFO Size Values

DSI_RX_FIFO_VC_SIZE.VCx_FIFO_SIZE[x = 0, 3]	Space Size (up to the size of the FIFO)
0	0 x 33 bits
1	32 x 33 bits
2	64 x 33 bits
3	96 x 33 bits
4	128 x 33 bits

The total size of RX FIFO is 128*33 bits. Therefore, the sum of all virtual channel FIFO allocation cannot exceed 128*33 bits.

[Table 7-69](#) indicates the start address of the space in the FIFO.

Table 7-69. Virtual Channel RX FIFO Start Address

DSI_RX_FIFO_VC_SIZE.VCx_FIFO_ADD[x = 0, 2]	Start Address
0	0
1	32
2	64
3	96
4	128

CAUTION

There must be no overlap of different VCs spaces.

While reading the received bytes in the RX FIFO, only the DSS.[DSI_VCn_SHORT_PACKET_HEADER](#) register is used since the hardware does not keep track of the header position for long packets and start/end of each packet. The software must extract the information from the bytes read from the RX FIFO. There is no specific hardware to track the received bytes in the RX FIFO. The DSS.[DSI_VCn_LONG_PACKET_HEADER](#) and DSS.[DSI_VCn_LONG_PACKET_PAYLOAD](#) registers are not used.

The ECC is only used by the first header when receiving multiple packets during the same LP RX transfer from the peripheral since the DSI Protocol engine does not parse the header to identify the length of the packets. In case of multiple packets, the Check-sum does not be enabled since the hardware checks the check-sum considering a single packet. The ECC in the first header is used to correct and check the header. For the following headers in the same LP RX transfer, the hardware does not detect any header and cannot check or/and detect errors in the headers of the packets except for the first packet.

When the RX FIFO is empty:

- there is no OCP error generated
- the commands are accepted and the data for the responses are 0s

7.5.4.10.3 Command Mode DMA Requests

The DMA requests (DSI_DMA_REQ) are used to allow automatic transfer by the system DMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the

system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported. The read and write accesses can use burst structure. The DSI protocol engine should access each write request in a burst without any IDLE between. For read OCP request in a burst to RX FIFO, the acceptance is sent immediately and the response is delayed by at least four L4 interface clock (DSS_L4_ICLK) cycles. In case of register reads, the response is returned in the first clock cycle.

The thresholds used for requests for the TX FIFO and RX FIFO are programmable by software. Users program the DSS.[DSI_VCn_CTRL\[19:17\]](#) DMA_TX_THRESHOLD and DSS.[DSI_VCn_CTRL\[26:24\]](#) DMA_RX_THRESHOLD bit fields for TX FIFO and RX FIFO, respectively. Hardware asserts the DMA request based on the threshold value. The size of the space allocated in TX FIFO for each VC must be a multiple of the DSS.[DSI_VCn_CTRL\[19:17\]](#) DMA_TX_THRESHOLD bit field value.

The only exception is in the case of the RX FIFO when the LP data transfer finishes and the threshold value is not reached. In that case the DMA request must be asserted. Therefore, the drain of the FIFO is supported in that configuration to empty the FIFO even if the number of data received is not a multiple of the threshold value.

In case of TX FIFO, if all the bytes defined by the word count field in the DSS.[DSI_VCn_LONG_PACKET_HEADER](#) header register have been received, the DMA request is no longer asserted even during the last transfer less than DMA_TX_THRESHOLD number of bytes have been received because of the word count being not a multiple of the DMA_TX_THRESHOLD value.

In case of RX FIFO, while the DMA request is used to transfer the data from the RX FIFO to the system memory, the system DMA must be programmed to read the number of received bytes in the FIFO. If users do not know the size of the received bytes, the direct access of the RX FIFO through the DSS.[DSI_VCn_SHORT_PACKET_HEADER](#) register is performed until the DSS.[DSI_VCn_CTRL\[20\]](#) RX_FIFO_NOT_EMPTY bit goes to 0.

The use of each DMA request is programmable by software. The DSS.[DSI_VCn_CTRL\[23:21\]](#) DMA_TX_REQ_NB is dedicated to DMA request numbering for the TX FIFO. The DSS.[DSI_VCn_CTRL\[29:27\]](#) DMA_RX_REQ_NB is dedicated to DMA request numbering for the RX FIFO.

When the DMA request is used to indicate the number of 32-bit values ready in the RX FIFO or BTA has been received from peripheral indicating end of the transfer from peripheral to host for a transfer to the system memory, the DMA request corresponding to the VC ID is generated.

The system DMA transfers the number of 32-bit values defined in the threshold register or the exact number of bytes received from the peripheral (user should know the number of expected received bytes to program correctly the system DMA). When the system DMA transfers a multiple number of threshold value, the DSI protocol engine should send 0s for the data when there is no more received data in the RX FIFO for the VC. Software users must parse the data and determine the valid bytes.

Software users can decide to determine the number of data received in the RX FIFO to read the information in the DSS.[DSI_RX_FIFO_VC_FULLNESS](#) register. Then the system DMA can be programmed to read the number of bytes from the RX FIFO. The BTA interrupt (BTA_IRQ) must be used to know when to read the number of received bytes. To monitor the BTA interrupt, the user must read the DSS.[DSI_VCn_IRQSTATUS\[5\]](#) BTA_IRQ status bit. The DMA request must not be selected until the system DMA is programmed with the correct number of data to read from RX FIFO.

If the RX FIFO space for the VC is expected to be overflow because the number of data to be received is greater than the space allocated for the VC, the previous programming model must be used. In place, the DMA request must be asserted as soon as the threshold is reached or when BTA is received.

When the DMA request is used to indicate the number of 33-bit entries empty in the TX FIFO for a transfer from the system memory, the DMA request corresponding to the VC ID is generated.

NOTE: To obtain best efficiency of the transfer the size of the request (read or write, single or burst) must be aligned with the threshold value.

Concurrent access using interlaced requests (read/write) to the TX and RX FIFO is supported for the same VC ID or different VC IDs.

7.5.4.11 Ultra-Low Power State

This section describes how to enter/exit to/from ultralow-power state (ULPS).

NOTE: The DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIGy bits (x range is 1 to 3 corresponding to lane #1 to lane #3, and y range is 1 to 2) must be read back after writing to verify that the write operations are effective before proceeding to the next step. This is to take latency at low TxClkEsc frequencies into account.

7.5.4.11.1 Entering ULPS

To enter into ULPS for a clock lane, the following sequence is required:

1. Wait for DSS.[DSI_COMPLEXIO_CFG2\[16\]](#) HS_BUSY and DSS.[DSI_COMPLEXIO_CFG2\[17\]](#) LP_BUSY bits to be reset to 0 and ensure that the DSS.[DSI_CLK_CTRL\[13\]](#) DDR_CLK_ALWAYS_ON bit is 0.
2. TxUlpsClk state changes from inactive to active by setting the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

To enter into ULPS for a data lane, the following sequence is required:

1. Wait for all TX_FIFOs for all VCs working in HS are empty, for video mode is not active, and for DSS.[DSI_COMPLEXIO_CFG2\[16\]](#) HS_BUSY bit is reset to 0 (in addition for data lane #1, DSS.[DSI_COMPLEXIO_CFG2\[17\]](#) LP_BUSY bit is reset to 0)
2. TxRequestEsc state changes from inactive to active by setting the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

NOTE: When the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG2 and DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

7.5.4.11.2 Exiting ULPS

To exit from ULPS for a clock lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.
2. Wait for the ULPSCACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is performed by monitoring the DSS.[DSI_COMPLEXIO_IRQSTATUS\[31\]](#) ULPSCACTIVENOT_ALL1_IRQ status bit.
3. Start the wake-up timer (GPTimer).
4. Wait for the time-out.
5. Change TxUlpsClk signals to INACTIVE state for the clock lane by resetting the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
6. Reset the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.

NOTE: When the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG2 and DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

To exit from ULPS for a clock lane, in case ComplexIO is in OFF state (the DSI protocol engine sends ComplexIO to OFF state by setting DSS.[DSI_COMPLEXIO_CFG1\[28:27\]](#) PWROFF = 0x0), the sequence is:

1. Change TxUlpsClk signals to INACTIVE state for the clock lane by resetting the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
2. Change the state of TxUlpsExit for clock lane to INACTIVE state by resetting the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0. This step is necessary only in case a PWROFF command (the command for power control of the complex I/O) is issued while the sequence for exiting is in progress (TxUlpsExit signal is already in ACTIVE state).

NOTE: When the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG2 and DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

To exit from ULPS for a data lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is performed by monitoring the DSS.[DSI_COMPLEXIO_IRQSTATUS\[31\]](#) ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the application wake-up timer (GPtimer).
4. Wait for the time-out.
5. Change TxRequestEsc signals to INACTIVE state for the data lane by resetting the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
6. Reset the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.

NOTE: When the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG2 and DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

To exit from ULPS for a data lane, in case ComplexIO is in OFF state (the DSI protocol engine sends ComplexIO into OFF state by setting DSS.[DSI_COMPLEXIO_CFG1\[28:27\]](#) PWROFF = 0x0), the sequence is:

1. Change TxRequestEsc signals to INACTIVE state by resetting the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
2. Change the state of TxUlpsExit to INACTIVE state by resetting the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0. This step is necessary only in case a PWROFF command is issued while the sequence for exiting is in progress (TxUlpsExit signal is already in ACTIVE state).

NOTE: When the DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG2 and DSS.[DSI_COMPLEXIO_CFG2](#) LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

When the sequence for entering/exiting into/from ULP state is started for specific lanes, users must wait for the sequence to complete before changing the state of the same or other lanes.

7.5.4.12 DSI Programming Sequence Example

This section describes distinct configurations of the DSI protocol engine to support different type of traffics.

NOTE: When the VC is used to send video mode data from the video port, the DSS.DSI_VCn_CTRL[9] MODE_SPEED and the DSS.DSI_VCn_CTRL[1] SOURCE bits are ignored.

7.5.4.12.1 Video Mode Transfer

Description: One channel, video mode, no DMA requests, no bus turn-around.

1. Configure the display controller with the timing parameters.
2. Configure the DSS.DSI_VCn_CTRL register as follows:
 - SOURCE bit is ignored by hardware
 - BTA_LONG_EN bit is set to 0: No BTA on long packet
 - BTA_SHORT_EN bit is set to 0: No BTA on short packet
 - MODE bit set to 1: The video mode is selected
 - MODE_SPEED bit is ignored by hardware
3. Configure the DSS.DSI_VM_TIMING1 to DSS.DSI_VM_TIMING7 registers.
4. Set the ForceTxStopMode bit to 1 in the DSS.DSI_TIMING1 register.
5. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
6. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1.
7. Poll the ForceTxStopMode bit to 0 in the DSS.DSI_TIMING1 register.
8. Enable the LCD video output by setting the DSS.DISPC_CONTROL[0] LCDENABLE bit to 1

CAUTION

The restriction for stopping the video mode is that no frame must be sent by the display controller (DISPC) after disabling video mode in DSI.

7.5.4.12.2 Command Mode Transfer Example 1

CAUTION

In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC_CONTROL[11] STALLMODE bit to 1.

Description: One channel, command mode, no DMA requests, manual bus turn-around

1. Configure the DSS.DSI_VCn_CTRL register as follows:
 - SOURCE bit set to 0: The source is the L4 interconnect port
 - BTA_LONG_EN bit is set to 0: No automatic BTA on long packet
 - BTA_SHORT_EN bit is set to 0: No automatic BTA on short packet
 - MODE bit set to 0: The command mode is selected
 2. Enable the packet sent interrupt by setting the DSS.DSI_VCn_IRQENABLE[2] PACKET_SENT_IRQ_EN bit to 1
 3. Set the ForceTxStopMode bit to 1 in the DSS.DSI_TIMING1 register.
 4. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
 5. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1
 6. Poll the ForceTxStopMode bit to 0 in the DSS.DSI_TIMING1 register.
- For long packet:
- Write the header value into the DSS.DSI_VCn_LONG_PACKET_HEADER register
 - Write the data into the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register for the full payload.

Repeat step until WC is reached (see [DSI_VCh_LONG_PACKET_HEADER](#))

For short packet:

- Send short packets through the L4 interconnect: Write the header value into the DSS.[DSI_VCn_SHORT_PACKET_HEADER](#) register. Repeat step for each short packet.

7. Send one or more packets through L4 interconnect:

- Write the header value into DSS.[DSI_VCn_LONG_PACKET_HEADER](#) register
- Write the data into DSS.[DSI_VCn_LONG_PACKET_PAYLOAD](#) register for the full payload.
- Repeat step 5 for all the long packets

8. Send short packets through L4 interconnect:

- Write the header value into DSS.[DSI_VCn_SHORT_PACKET_HEADER](#) register
- Repeat step 6 for all the short packets

9. Interrupt routine: Wait for PACKET_SENT_IRQ interrupt generation by polling the DSS.[DSI_VCn_IRQSTATUS\[2\]](#) PACKET_SENT_IRQ status bit and notify the application software when received.

10. The applicative software forces the bus turn-around:

- Wait until the PACKET_SENT_IRQ has happened as many times as the number of sent packets
- Set the DSS.[DSI_VCn_CTRL\[6\]](#) BTA_EN bit to 1 to send manually a BTA
- Wait until the DSS.[DSI_VCn_CTRL\[6\]](#) BTA_EN bit is reset to 0 by hardware

11. Receive the packets from the peripheral

- Start polling the DSS.[DSI_VCn_CTRL\[20\]](#) RX_FIFO_NOT_EMPTY status bit
- Whenever the RX_FIFO_NOT_EMPTY bit equals to 1, read one word in the RX FIFO

7.5.4.12.3 Command Mode Transfer Example 2

CAUTION

In DSI command mode, the display controller must be configured in stall mode by setting the DSS.[DISPC_CONTROL\[11\]](#) STALLMODE bit to 1.

Description: One channel, command mode, DMA request, automatic bus turn-around

1. Configure the DSS.[DSI_VCn_CTRL](#) register as follows:

- SOURCE bit set to 0: The source is the L4 interconnect port
- BTA_LONG_EN bit is set to 1: Automatic BTA on long packet
- BTA_SHORT_EN bit is set to 1: Automatic BTA on short packet
- MODE bit set to 0: The command mode is selected

2. Enable the packet sent interrupt by setting the DSS.[DSI_VCn_IRQENABLE\[2\]](#) PACKET_SENT_IRQ_EN bit to 1

3. Set the ForceTxStopMode bit to 1 in DSS.[DSI_TIMING1](#) register.

4. Enable the channel by setting the DSS.[DSI_VCn_CTRL\[0\]](#) VC_EN bit to 1

5. Configure the TX FIFO threshold and DMA requests parameters:

- Program the DSS.[DSI_VCn_CTRL\[19:17\]](#) DMA_TX_THRESHOLD bit field
- Program the DSS.[DSI_VCn_CTRL\[23:21\]](#) DMA_TX_REQ_NB bit field

6. Program the system DMA to be ready to send data to the L4 interconnect port

7. Enable the module by setting the DSS.[DSI_CTRL\[0\]](#) IF_EN bit to 1

8. Poll the ForceTxStopMode bit to 0 in DSS.[DSI_TIMING1](#) register.

9. Write the header value into DSS.[DSI_VCn_LONG_PACKET_HEADER](#) register

10. Interrupt routine: Wait for PACKET_SENT_IRQ interrupt generation by polling the DSS.[DSI_VCn_IRQSTATUS\[2\]](#) PACKET_SENT_IRQ status bit and notify the application software

when received.

11. Receive the packets from the peripheral
 - Start polling the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY status bit
 - Whenever the RX_FIFO_NOT_EMPTY bit equals to 1, read one 32-bit word in the RX FIFO
12. Repeat the steps 7 for all long packets.

7.5.5 DSI PLL Controller Basic Programming Model

7.5.5.1 Software Reset

The DSI PLL control module does not have its own software reset. It is reset by the DSI protocol engine. Nevertheless, software users can monitor the reset status of the DSI PLL control module by reading the DSS.DSI_PLL_STATUS[0] DSPLLCTRL_RESET_DONE status bit.

7.5.5.2 DSI PLL Programming Blocks

Figure 7-135 shows the DSI PLL programming blocks.

Figure 7-135. DSI PLL Programming Blocks

dss-181

7.5.5.3 DSI PLL Go Sequence

In Manual Mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 0), the DPLL requires a sequence on TINITZ, TENABLE and TENABLEDIV to update the configuration values and start the locking sequence.

Once all the configuration values have been programmed into the registers, the GO bit must be set. The appropriate sequence should then be sent on the TINITZ, TENABLE, and TENABLEDIV pins, respecting the timing requirements of the ADPLLM. The DSS.DSI_PLL_GO[0] **DSI_PLL_GO** bit are cleared to 0 at the end of the sequence.

Because the TENABLEDIV signal is shared with the HSDIVIDER module, it is programmed at the same time. In this mode, software must deassert CLKINEN by unsetting the DSS.DSI_PLL_CONFIGURATION2[14] DS1_PHY_CLKINEN to 0 and assert HSDIVBYPASS correctly by setting the DSS.DSI_PLL_CONFIGURATION2[20] DS1_HSDIVBYPASS bit to 1 to prevent uncontrolled frequencies affecting the DS1_PHY and display subsystem during PLL locking. In manual mode the shadow register must be updated anyway so that valid values are present when later selecting automatic mode.

Figure 7-136 shows the DS1 PLL Go flow chart in manual mode (DSS.DSI_PLL_CONTROL[0] DS1_PLL_AUTOMODE bit set to 0).

Figure 7-136. DS1 PLL Go Sequence (Manual Mode)

dss-182

NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

In automatic mode (DSS.DSI_PLL_CONTROL[0] DS1_PLL_AUTOMODE bit set to 1), the TINITZ, TENABLE and TENABLEDIV sequence and the update of the PLL configuration from the DS1_PLL_CONFIGURATION2 register are deferred until the time of the front porch time signal sent by the DISPC module. This is intended to simplify the software to implement a configuration change (such as a frequency change to support a different link bandwidth). In this mode CLKINEN, HSDIVBYPASS and REFEN are controlled automatically and the register value is overridden.

Figure 7-137 shows the DS1 PLL Go flow chart in automatic mode (DSS.DSI_PLL_CONTROL[0] DS1_PLL_AUTOMODE bit set to 1).

Figure 7-137. DSI PLL Go Sequence (Automatic Mode)

dss-183

NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

7.5.5.4 DSI PLL Clock Gating Sequence

Clock gating can be used to reduce system power consumption when the DSI protocol engine indicates that it does not need the clock. If the HSDIVIDER is not used, the PLL can also be stopped (at the cost of additional unstarting latency).

The DSI protocol engine can verify when the PLL has unstarted by inspecting the LOCK signal (DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit). Because TxByteClkHS is stopped when the CLKIN4DDR is stopped, this should obviate the need for any explicit feedback that the clock has been unstarted in the other case. This flow chart should run even if the DSS.DSI_PLL_GO[0] DSI_PLL_GO bit has not been set.

[Figure 7-138](#) shows the DSI PLL gated mode sequence.

Figure 7-138. Gated Mode Sequence

dss-184

NOTE: All thick-outlined blocks show operations performed by software.

7.5.5.5 DSI PLL Lock Sequence

The DSI PLL (ADPLLM) generates the CLKIN4DDR clock. The HSDIVIDER generates two clocks: DSI1_PLL_FCLK connected to the display controller (DISPC) and the DSI2_PLL_FCLK connected to the DSI protocol engine. If these two clocks are not used, the HSDIVIDER functions are not required.

The CLKIN4DDR is twice the data rate, and is four times the DSI output clock frequency. The DSI PLL factors need to be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency in the appropriate range:

- REGM factor is programed by DSS.DSI_PLL_CONFIGURATION1[18:8] DS1_PLL_REGM bit field
- REGN factor is programed by DSS.DSI_PLL_CONFIGURATION1[7:1] DS1_PLL_REGN bit field
- REGM3 factor is programed by DSS.DSI_PLL_CONFIGURATION1[22:19] DS1_CLOCK_DIV bit field
- REGM4 factor is programed by DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV bit field

Figure 7-139 shows the programming sequence.

Figure 7-139. DS1 PLL Programming Sequence

camdss-190

NOTE:

- The REGM3 and REGM4 factors must according with the following conditions:
 - The DSI1_PLL_FCLK and DSI2_PLL_FCLK frequencies must be a multiple of the PCLK frequency (for proper settings of PCD and LCD factors in the DISPC).
 - The DSI1_PLL_FCLK and DSI2_PLL_FCLK frequencies must be lower than 173 MHz at nominal voltage (OPP100), and lower than 100 MHz at low voltage (OPP50).
- Most of the other DS1 PLL programming values are available for software flexibility but it is not recommended to update the values in normal use. See [Section 7.5.5.7](#) for details on DS1 PLL recommended values.

DSI PLL programming examples:

- WVGA Display on one data pair: Pixel clock (PCLK) = 30 MHz with 18-BPP pixel format

The data rate is $30 \times 18 = 540$ Mbps on one data lane. Therefore, the frequency on the data lane is twice the data rate: 1080 MHz.

The frequency on the clock lane is 270 MHz (1080 divided by 4).

The SYS_CLK at 26 MHz is selected as the clock reference by setting the DSS.[DSI_PLL_CONFIGURATION2\[11\]](#) DS1_PLL_CLKSEL to 0b0.

Set the DSS.[DSI_PLL_CONFIGURATION2\[12\]](#) DS1_PLL_HIGHFREQ to 0b0 as PCLK is lower than 32 MHz.

Set Fint to 2 MHz as PLL internal reference frequency: Set REGN to 12 (divide by 13) by setting the DSS.[DSI_PLL_CONFIGURATION1\[7:1\]](#) DS1_PLL_REGN bit field to 0xC.

To get the CLKIN4DDR to 1080 MHz, set the REGM factor to 270 by setting the DSS.[DSI_PLL_CONFIGURATION1\[18:8\]](#) DS1_PLL_REGM to 0x10E.

$$\text{DSI_PHY} = 2 \times 270/13 \times 26/1 = 1080 \text{ MHz}$$

Because DSI1_PLL_FCLK and DSI2_PLL_FCLK (REGM3 and REGM4 factors) must be multiples of PCLK and also lower than 173 MHz at nominal voltage (OPP100), and lower than 100 MHz at low voltage (OPP50), program these frequencies to 90 MHz by setting the REGM3 and REGM4 factors to 11 (divide by 12). This is done by setting the DSS.[DSI_PLL_CONFIGURATION1\[22:19\]](#) DSS_CLOCK_DIV bit field and DSS.[DSI_PLL_CONFIGURATION1\[26:23\]](#) DSIPROTO_CLOCK_DIV to 0xB:

$$\text{DSI1_PLL_FCLK} = \text{DSI2_PLL_FCLK} = 1080/12 = 90 \text{ MHz}$$

- XGA Display on two data pairs: Pixel clock (PCLK) = 60 MHz with 16-BPP pixel format

The data rate is $(60 \times 16)/2 = 480$ Mbps on each data lane. Therefore, the frequency on the data lane is twice the data rate: 960 MHz.

The frequency on the clock lane is 240 MHz (960 divided by 4).

The SYS_CLK at 26 MHz is selected as the clock reference by setting the DSS.[DSI_PLL_CONFIGURATION2\[11\]](#) DS1_PLL_CLKSEL bit to 0b0.

Set the DSS.[DSI_PLL_CONFIGURATION2\[12\]](#) DS1_PLL_HIGHFREQ bit to 0b0 as the source clock frequency (SYS_CLK in this example) is lower than 32 MHz.

Set Fint to 2 MHz as PLL internal reference frequency: Set REGN to 12 (divide by 13) by setting the DSS.[DSI_PLL_CONFIGURATION1\[7:1\]](#) DS1_PLL_REGN bit field to 0xC.

To get the CLKIN4DDR to 960 MHz, set the REGM factor to 240 by setting the DSS.[DSI_PLL_CONFIGURATION1\[18:8\]](#) DS1_PLL_REGM to 0x0F0.

$$\text{DSI_PHY} = 2 \times 240/13 \times 26/1 = 960 \text{ MHz}$$

Because DSI1_PLL_FCLK and DSI2_PLL_FCLK (REGM3 and REGM4 factors) must be multiples of PCLK and also lower than 173 MHz at nominal voltage (OPP100), program these frequencies to 120 MHz by setting the REGM3 and REGM4 factors to 7 (divide by 8). This is done by setting the DSS.[DSI_PLL_CONFIGURATION1\[22:19\]](#) DSS_CLOCK_DIV bit field and DSS.[DSI_PLL_CONFIGURATION1\[26:23\]](#) DSIPROTO_CLOCK_DIV to 0x7:

$DSI1_PLL_FCLK = DSI2_PLL_FCLK = 960/8 = 120 \text{ MHz}$

7.5.5.6 DSI PLL Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.[DSI_PLL_STATUS\[1\]](#) DSI_PLL_LOCK status bit gives the DSI PLL lock state.
- The DSS.[DSI_PLL_STATUS\[2\]](#) DSI_PLL_RECAL status bit informs if the PLL must be uncalibrated

These signals can also generate interrupts at DSI protocol engine level:

- DSS.[DSI_IRQSTATUS\[9\]](#) PLL_RECAL_IRQ bit
- DSS.[DSI_IRQSTATUS\[8\]](#) PLL_UNLOCK_IRQ
- DSS.[DSI_IRQSTATUS\[7\]](#) PLL_LOCK_IRQ

The PLL_LOCK_IRQ interrupt indicates that the DSI PLL is locked. To monitor this event, read the DSS.[DSI_IRQSTATUS\[7\]](#) PLL_LOCK_IRQ bit. Set this bit to 1 to clear the status bit.

The PLL_UNLOCK_IRQ interrupt indicates that the DSI PLL is unlocked. To monitor this event, read the DSS.[DSI_IRQSTATUS\[8\]](#) PLL_UNLOCK_IRQ bit. Set this bit to 1 to clear the status bit.

The PLL_RECAL_IRQ interrupt indicates that the DSI PLL must be recalibrated. To monitor this event, read the DSS.[DSI_IRQSTATUS\[9\]](#) PLL_RECAL_IRQ bit. Set this bit to 1 to clear the status bit.

The PLL reference loss and limp status signals can also be monitored:

- The DSS.[DSI_PLL_STATUS\[3\]](#) DSI_PLL_LOSSREF status bit informs if the DSI PLL has lost the reference.
- The DSS.[DSI_PLL_STATUS\[4\]](#) DSI_PLL_LIMP status bit informs about the DSI PLL limp status.

7.5.5.7 DSI PLL Recommended Values

[Table 7-70](#) shows the DSI PLL recommended values.

Table 7-70. Recommended Programming Values

Field Name	Value	Description
DSI_HSDIV_SYSRESET	0	Allow power FSM to control
DSI_PLL_SYSRESET	0	Allow power FSM to control
DSI_PLL_HALTMODE	-	See Section 7.5.5.4 for details
DSI_PLL_GATEMODE	-	See Section 7.5.5.4 for details
DSI_PLL_AUTOMODE	-	See Section 7.5.5.4 for details
DSI_PLL_GO	1-0	Write a 1 when PLL is to be (re-)locked with new parameters. This bit is cleared by hardware when the PLL request has completed
DSIPROTO_CLOCK_DIV	See ⁽¹⁾	DSI protocol engine clock divider
DSS_CLOCK_DIV	See ⁽¹⁾	DSS clock divider
DSI_PLL_REGM	See ⁽¹⁾	Feedback clock divider
DSI_PLL_REGN	See ⁽¹⁾	Reference clock divider
DSI_PLL_STOPMODE	1	Required to use GATEMODE bit
DSI_HSDIVBYPASS	0	PLL is controlling HSDIVIDER bypass
DSI_PROTO_CLOCK_PWDN	0	If PLL/HSDIVIDER is used as the DSI protocol clock source
DSI_PROTO_CLOCK_EN	1	If PLL/HSDIVIDER is used as the DSI protocol clock source
DSS_CLOCK_PWDN	0	If PLL/HSDIVIDER is used as the DSS clock source
DSS_CLOCK_EN	1	If PLL/HSDIVIDER is used as the DSS clock source

⁽¹⁾ The bit field value must be set according to the desired clock frequency.

Table 7-70. Recommended Programming Values (continued)

Field Name	Value	Description
DSI_BYPASSEN	0	To use PLL as the clock source. For small displays it may be possible to use the DSS functional clock, in which case this bit must be set to 1
DSI_PHY_CLKINEN	1	Enable CLKIN4DDR
DSI_PLL_REFEN	1	Enable PLL reference
DSI_PLL_HIGHFREQ	0/1	Set to 1 if the clock reference is higher than 32 MHz (21 MHz if DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN = 0)
DSI_PLL_CLKSEL	0/1	Set to 0 to use DSS2_ALWON_FCLK as the PLL reference or set to 1 to use PCLKFREE as the PLL reference, in this case the DISPC must be using DSS1_ALWON_FCLK.
DSI_PLL_LOCKSEL	0x0	Phase lock criteria to lock the PLL
DSI_PLL_DRIFTGUARDEN	0x0	The RECAL status/interrupt must be used to decide when to perform a PLL uncalibration No automatic uncalibration is performed
DSI_PLL_TIGHTPHASELOCK	0	Normal criteria
DSI_LOWCURRSTDBY	0/1	Set to 0 for fast PLL unlock, but higher standby current Set to 1 for leakage level standby current, but longer unlock time
DSI_PLL_PLLLPMODE	0	Normal operation For smaller display sizes may be possible to set to 1
DSI_PLL_IDLE	0	PLL active

7.5.6 DSI Complex I/O Basic Programming Model

7.5.6.1 Software Reset

The clock domain using the TxByteClkHS from the DSI complex I/O has a dedicated reset done information in the DSS.DSI_COMPLEXIO_CFG1[29] RESET_DONE bit. The DSS.DSI_SYSCONFIG[1] SOFT_RESET bit is used to reset the TxByteClkHS power domain. A dummy read using the SCP interface to any DSI_PHY register is required after DSI_PHY reset to complete the reset of the DSI complex I/O.

7.5.6.2 Reset-Done Bits

The DSI complex I/O has several clock domains. The reset status for each clock domain is provided in DSS.DSI_PHY_REGISTER5 register:

- DSS.DSI_PHY_REGISTER5 [31] RESETDONETXBYTECLK bit : Reset done for the TXBYTECLK domain.
- DSS.DSI_PHY_REGISTER5 [26:24] RESETDONETXCLKESCi bits: Reset done for the TXCLKESC domain for lane i (i between 0 and 2).
- DSS.DSI_PHY_REGISTER5 [30] RESETDONESCPCLK bit: Reset done for the SCP clock domain. Software users must perform a dummy read on this bit to initiate the reset sequence of the SCP finite state machine. When the reset sequence is complete, the RESETDONESCPCLK signal goes high and software users can read again the DSS.DSI_PHY_REGISTER5 [30] RESETDONESCPCLK bit to ensure that the value is now 1.

NOTE: Software must not write in the DSI_PHY_SCP registers before the DSS.DSI_PHY_REGISTER5 [30] RESETDONESCPCLK bit is set to 1.

- DSS.[DSI_PHY_REGISTER5](#) [29] RESETDONEPWRCLK bit: Reset done for the PWR clock domain. The reset sequence of the PWR finite state-machine is complete when the RESETDONEPWRCLK signal goes high.

7.5.6.3 Pad Configuration

The number of lanes is configurable through the DSS.[DSI_COMPLEXIO_CFG1](#) register.

It is not allowed to change on the fly the position (by modifying the DATA i _POSITION with $i = 1$ or 2 and CLOCK_POSITION bit fields), P/N order (Positive/Negative order of the differential pair by modifying the DATA i _POL with $i = 1$ or 2 and CLOCK_POL) or number of active data lanes (by modifying the DSS.[DSI_COMPLEXIO_CFG1\[10:8\]](#) DATA2_POSITION bit). To add or remove the lane #2, it is required to be in OFF mode for the DSI complex I/O.

The minimum requirement for the number of lanes is one clock lane and one data lane. Note that by default, the data lane 2 is not connected (the DSS.[DSI_COMPLEXIO_CFG1\[10:8\]](#) DATA2_POSITION bit reset value is 0).

7.5.6.4 Display Timing Configuration

NOTE: Copyright © 2005-2008 MIPI Alliance, Inc. All rights reserved. MIPI Alliance Member Confidential.

Depending on the CLKIN4DDR frequency settings programmed with the DSI PLL control module, software users must program accordingly the timing parameters in the DSI complex I/O registers.

7.5.6.4.1 High-Speed Clock Transmission

Figure 7-140 shows an example of high-speed Clock Transmission.

Figure 7-140. High-Speed Clock Transmission

dss-185

TXByteClkHS is an output clock which is derived by dividing CLKIN4DDR by 16.

To begin transmission, the protocol drives TXREQUESTHS high on a rising edge of TXByteClkHS. The PHY detects this signal on the next rising edge, following which it initiates the LP Start of Transmission (SoT) procedure.

During a high-speed Clock Transmission, these parameters are defined in multiples of CLKIN4DDR and programmed by the following register bit fields:

- TLPX timing is programmed by the DSS.[DSI_PHY_REGISTER1\[20:16\]](#) REG_TLPXBY2 bit field.
- THS-PREPARE timing is programmed by the DSS.[DSI_PHY_REGISTER0\[31:24\]](#) REG_THSPREPARE bit field.
- TCLK-ZERO timing is programmed by the DSS.[DSI_PHY_REGISTER1\[7:0\]](#) REG_TCLKZERO bit field. TCLK-ZERO is extended, if required, so that the entire LP SoT procedure lasts an integer number of TXByteClkHS cycles.

At the end of the SoT procedure, HS clock transmission begins. At the same time, TXREADYHS is made high.

To stop clock transmission, the protocol drives TXREQUESTHS low on a rising edge of TXByteClkHS. The DSI_PHY detects this change in TXREQUESTHS on the next edge and stops clock transmission. TXREADYHS is made low.

The DSI_PHY then goes through the LP End of Transmission (EoT) procedure. TCLK-TRAIL and THS-EXIT parameters are also multiples of CLKIN4DDR and programmed by the following register fields:

- TCLK-TRAIL timing is programmed by the DSS.[DSI_PHY_REGISTER1\[15:8\]](#) REG_TCLKTRAIL bit field.
- THS-EXIT timing is programmed by the DSS.[DSI_PHY_REGISTER0\[7:0\]](#) REG_THSEXIT bit field.

The DSI_PHY completes the SoT and EoT procedures, once begun, irrespective of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY start the EoT procedure immediately after finishing the SoT procedure and no clock is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the Low Power Receivers. This signal is not synchronized with TXByteClkHS.

It is requires that the high speed clock be present for some time before (TCLK-PRE) and some time after (TCLK-POST) high speed data transmission. The protocol must ensure that these timings are met by asserting and deasserting TXREQUESTHS appropriately.

The PHY ensures that the clock signal has a quadrature-phase with respect to a toggling bit sequence on any Data Lane, and a rising edge in the center of the first transmitted bit of every Data byte. These relations are not described in the timing diagram.

CLKIN4DDR can be shut off 300ns after the clock lane goes to STOPSTATE. Alternatively, CLKIN4DDR can be shut down after TCLK-Trail + THS-Exit + 2 Txbyteclk periods after TxRequestHS falling edge is received by DSI_PHY.

The DSI protocol engine must ensure that TXREQUESTESC, TXULPSCLK, and TURNREQUEST are low whenever TXREQUESTHS is asserted.

7.5.6.4.2 High-Speed Data Transmission

[Figure 7-141](#) shows an example of high-speed Data Transmission.

Figure 7-141. High-Speed Data Transmission

dss-186

TXByteClkHS is an output clock which is derived by dividing CLKIN4DDR by 16.

To begin transmission, the protocol drives TXDATAHS with the first byte of data on a rising edge of TXByteClkHS. It also makes TXREQUESTHS high the same rising edge. The PHY detects TXREQUESTHS going high on the next rising edge of TXByteClkHS, following which it initiates the LP Start of Transmission (SoT) procedure.

During a high-speed Data Transmission, these timings are multiple of CLKIN4DDR and programmed by the following register bit fields:

- TLPX timing is programmed by the DSS.[DSI_PHY_REGISTER1\[20:16\]](#) REG_TLPXBY2 bit field.
- THS-PREPARE + THS-ZERO timing is programmed by the DSS.[DSI_PHY_REGISTER0\[23:16\]](#) REG_THSPRPR_THSZERO bit field.

THS-ZERO will be extended, if required, so that the entire LP SoT procedure lasts an integer number of TXByteClkHS cycles. THS-SYNC corresponds to the length of the sync pattern which is 8 high-speed bits, and can be configured through the [DSI_PHY_REGISTER2\[31:24\]](#) HSSYNCPATTERN bit field.

Towards the end of the SoT procedure, the PHY makes TXREADYHS high on a positive edge of TXByteClkHS and then start accepting data from TXDATAHS from the next positive edge onwards. The protocol is expected to provide (new) valid data on TXDATAHS on every positive edge of TXByteClkHS if TXREADYHS is high.

At the end of the SoT procedure, HS data transmission begins. HS Data Transmission happens LSB first.

To stop data transmission, the protocol drives TXREQUESTHS low on a rising edge of TXByteClkHS. The PHY detects this change in TXREQUESTHS on the next edge and stops data transmission. TXREADYHS is made low and data on TXDATAHS, from that point, is ignored.

The PHY then goes through the LP End of Transmission (EoT) procedure. THS-TRAIL and THS-EXIT are also multiples of CLKIN4DDR and programmed by the following register bit fields:

- THS-TRAIL timing is programmed by the DSS.[DSI_PHY_REGISTER0\[15:8\]](#) REG_THSTRAIL bit field.
- THS-EXIT timing is programmed by the DSS.[DSI_PHY_REGISTER0\[7:0\]](#) REG_THSEXIT bit field.

The PHY completes the SoT and EoT procedures, once begun, irrespective of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY starts the EoT procedure immediately after finishing the SoT procedure and no data is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the low power receivers. This signal is not synchronized with TXByteClkHS.

The protocol must ensure that TXREQUESTESC, TXULPSCLK, and TURNREQUEST are low whenever TXREQUESTHS is asserted.

7.5.6.4.3 Turn-Around Request in Transmit Mode

When the DSI PHY is in transmit mode, the DSI protocol engine can request a turnaround by making the TurnRequest signal high for at least one clock cycle of TxClkEsc (see [Section 7.4.3.7.3, TurnRequest FSM](#)).

The DSI PHY transmits the turn-around request pattern (LP 11-10-00-10-00-00-00-00) (see [Figure 7-142](#)). The number of 00 states in the end of the pattern is defined by T_{TA_GO} timing parameter and is programmable through the DSS.[DSI_PHY_REGISTER1\[31:29\]](#) REG_TTAGO bit field, in number of TxClkEsc clocks. Following the transmission of the pattern, the DSI PHY disables its LP transmitters and waits for an acknowledgment from the remote device. The remote device detects the turn-around request and acknowledges it by driving LP-10, followed by the STOP state. When this acknowledgment is received (BTA_IRQ is asserted, as described in [Section 7.4.3.8, Bus Turnaround](#)), DSI PHY switches to receive mode and indicates the completion of the turn-around procedure by changing the direction (BTA_EN = 0).

Figure 7-142. Turn-Around Request in Transmit Mode

The DSI protocol engine must not stop TxClkEsc after the turn-around process completes (the DSS.[DSI_CLK_CTRL\[20\]](#) LP_CLK_ENABLE bit must be kept at 1), because TxClkEsc is also used in handling a turn-around request transmitted by a remote slave device (see [Section 7.5.6.4.4, Turn-Around Request in Receive Mode](#)).

7.5.6.4.4 Turn-Around Request in Receive Mode

When the DSI PHY is in receive mode, an LP pattern of 11-10-00-10-00 indicates a turn-around request from the remote device (see [Figure 7-143](#)).

Figure 7-143. Turn-Around Request in Receive Mode

If the line stays in LP-00 for a time $T_{TA-SURE}$, DSI PHY accepts the turn-around request, changes the direction, transmits LP-00 for a time T_{TA-GET} , and then transmits the acknowledgment pattern LP-10, followed by the STOP state.

This completes the turn-around procedure (`BTA_IRQ` is asserted, as described in [Section 7.4.3.8, Bus Turnaround](#)). The $T_{TA-SURE}$ and T_{TA-GET} timing parameters are programmable through `DSS.DSI_PHY_REGISTER1` in number of TxClkEsc clocks:

- $T_{TA-SURE}$ can be configured in the [28:27] `REG_TTASURE` bit field.
- T_{TA-GET} can be configured in the [26:24] `REG_TTAGET` bit field.

7.5.6.4.5 Other DSI_PHY Transmission and Reception

The timing of the following sequences defined in the DSI_PHY protocol cannot be programmed by users:

- Low-power data transmission
- Escape mode trigger command transmission
- ULP state command transmission on data lanes
- ULP state transmission on clock lane
- Low-power data in receive mode
- Low-power trigger in receive mode
- ULP state command on clock lane in receive mode
- ULP state command on data lane in receive mode

7.5.6.5 Error Handling

A dedicated register for the DSI complex I/O, `DSS.DSI_COMPLEXIO_IRQSTATUS`, indicates the state of each error provided by the DSI complex I/O error signals. The DSI_PHY reports the following errors:

- `DSS.DSI_COMPLEXIO_IRQSTATUS[7:5]` `ERR_ESCi_IRQ`: ERRESC is asserted if an unrecognized Escape entry command is received. This remains high until the next change in the line state.
- `DSS.DSI_COMPLEXIO_IRQSTATUS[2:0]` `ERRSYNCESCi_IRQ`: If the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends, ERRSYNCESC is made high and remains high until the next change in line state.
- `DSS.DSI_COMPLEXIO_IRQSTATUS[12:10]` `ERRCONTROLi_IRQ`: ERRCONTROL is asserted if an incorrect line state sequence is detected. For example, if a turn-around request or escape mode request is immediately followed by a Stop state instead of the required Bridge state, this signal is asserted and remains asserted until the next change in the line state.

- DSS.[DSI_COMPLEXIO_IRQSTATUS](#) ERRCONTENTIONLP0_i_IRQ: ERRCONTENTION0LPDX and ERRCONTENTION0LPDY are asserted when the Lane module detects a contention situation on lines DX and DY respectively while trying to drive the lines low. Contention is detected only if it lasts at least 50ns
- DSS.[DSI_COMPLEXIO_IRQSTATUS](#) ERRCONTENTIONLP1_i_IRQ: ERRCONTENTION1LPDX and ERRCONTENTION1LPDY are asserted when the Lane module detects a contention situation on lines DX and DY respectively while trying to drive the lines high. Contention is detected only if it lasts at least 50ns

The ULPSACTIVENOT signal goes low which indicates to the protocol that the PHY has entered ULP state. When all the ULPSActiveNot signals are low, the DSS.[DSI_COMPLEXIO_IRQSTATUS](#)[30] ULPSACTIVENOT_ALL0_IRQ event is generated. When all the ULPSActiveNot signals are high, the DSS.[DSI_COMPLEXIO_IRQSTATUS](#)[31] ULPSACTIVENOT_ALL1_IRQ event is generated.

When any of the events defined in DSS.[DSI_COMPLEXIO_IRQSTATUS](#) register happened, the DSS.[DSI_IRQSTATUS](#)[10] COMPLEXIO_ERR_IRQ bit is set to 1 at DSI protocol engine level.

The software must take appropriate action when receiving the interrupt indicating the error from the complex I/O. The action can be:

- Reset of the DSI protocol engine module
- Reset of the peripheral though reset trigger or directly driving the hardware reset pin of the display module
- Ignore the error

7.5.7 RFBI Basic Programming Model

The RFBI programming model must be used for LCD display support only.

7.5.7.1 DISPC Control Registers

The following DISPC registers are used in RFBI mode:

- The STALL mode is selected by setting the DSS.[DISPC_CONTROL](#)[11] STALLMODE bit. The DSS.[DISPC_CONTROL](#)[5] GOLCD bit must not be set to 1, but the display controller configuration (DMA engine, pipelines associated to the LCD output,...) must be set before enabling the LCD output by setting the DSS.[DISPC_CONTROL](#)[0] LCDENABLE bit to 1.
- To enable the hardware handcheck to avoid underflow, the DSS.[DISPC_CONTROL](#)[16] FIFOHANDCHECK must be set to 1. The reset value of this bit is 0. The handcheck applies to the pipelines connected to the LCD output. It must be disabled before resetting the DSS.[DISPC_CONTROL](#)[11] STALLMODE bit to 0. The new setting for the FIFO handcheck is used for the following frames.

NOTE: The LCD output is disabled at the end of the transfer of the frame. The software must reenable the LCD output to generate a new frame by setting the DSS.[DISPC_CONTROL](#)[0] LCDENABLE to 1. See [Figure 7-144](#).

7.5.7.2 RFBI Control Registers

The following registers define the RFBI control registers:

- DSS.[RFBI_CONTROL](#)
- DSS.[RFBI_PIXEL_CNT](#)
- DSS.[RFBI_LINE_NUMBER](#)

7.5.7.2.1 High Threshold

The DSS.[RFBI_CONTROL](#)[6:5] HIGHTHRESHOLD bit field is used to define the threshold to be used for the generation of the DMA request to receive data into the interconnect FIFO (24 x 32 FIFO depth) through the address of the register [RFBI_DATA](#). It must be the size of the burst. The supported values are

4x32, 8x32 and 16x32. The system DMA receives the DMA request and is in charge of providing the correct number of bytes. If the DSS.[RFBI_CONTROL\[7\]](#) DISABLE_DMA_REQ bit is reset, the DMA request is generated when there is enough room in the interconnect FIFO to accept the full burst. In case the RFBI receives writes L4 requests to the [RFBI_DATA](#) location when the interconnect FIFO is full, the request is not accepted. The RFBI waits for a free entry in the interconnect FIFO to accept the L4 request.

If the DSS.[RFBI_CONTROL\[7\]](#) DISABLE_DMA_REQ bit is set, the DMA request is not generated. The threshold value is ignored.

NOTE: Software users can access the [RFBI_DATA](#) location without using the DMA request and without programming the high threshold value (backward mode).

7.5.7.2.2 Bypass Mode

Setting the DSS.[RFBI_CONTROL\[1\]](#) BYPASSMODE bit directly outputs the LCD controller output to the LCD panel. Resetting this bit directs the MPU module to send commands/parameters and data from the input video port FIFO.

7.5.7.2.3 Enable

Setting/resetting the DSS.[RFBI_CONTROL\[0\]](#) ENABLE bit enables/disables the RFBI module. The hardware resets the enable bit after all of the pixels are sent to the panel. The DSS.[RFBI_PIXEL_CNT\[31:0\]](#) PIXELEMNT bit field value defines the number of pixels to send to the LCD panel. When the transfer is finished, the configuration used can be modified.

Table 7-71. RFBI Behavior

RFBI_CONTROL[1] BYPASSMODE bit value	RFBI_CONTROL[0] ENABLE bit value	RFBI Behavior
0	0	L4 interconnect can write command/param/data and read data/status from the Remote Frame Buffer (RFB). L4 interconnect access can only be done to the CSx actually active
0	1	The DISPC sends pixels to the RFB.

The stall signal is asserted when the module is disabled. Through the L4 port, pixels can be sent to the LCD panel only when the pixel count has reach the value 0x0

NOTE: The LCD output is disabled at the end of the transfer of the frame. The software must reenable the LCD output to generate a new frame by setting the DSS.[DISPC_CONTROL\[0\]](#) LCDENABLE to 1. See [Figure 7-144](#).

7.5.7.2.4 Configuration Selection

Setting the DSS.[RFBI_CONTROL\[3:2\]](#) CONFIGSELECT bit field selects the configuration number (1 or 0 if bits are set or reset). The registers associated with the configuration output the data to the LCD panel.

If both chip-selects are selected, the configuration for the first chip-select is used (except for the polarity of the RFBI_CS1 signal defined by the second configuration) and both devices connected to the CS signals are driven in parallel. In read mode, if both chip-selects are set, only RFBI_CS0 is asserted to read data from the device connected on RFBI_CS0. In write mode with two chip-selects selected, the RFBI can write to the two devices simultaneously.

7.5.7.2.5 ITE Bit

Set the DSS.[RFBI_CONTROL\[4\]](#) ITE bit to start capturing the data from the display controller. This bit has no effect if the trigger mode is set to external. The display controller must be configured in the STALL mode to account for the RFBI_DISPC_STALL signal. Setting the trigger mode to external (DSS.[RFBI_CONFIG\[3:2\]](#) TRIGGERMODE bit field set to 0x1 or 0x2) causes the DSS.[RFBI_CONTROL\[4\]](#) ITE bit to be ignored. The corresponding chip-select must be selected when this bit is set by users.

The RFBI_DISPC_STALL signal is asserted when at least one of the following cases occur:

- Default status when no data to capture from the display controller
- High FIFO threshold reached
- End of the transfer (number of data to output)
- Reset of the RFBI module
- DSS.[RFBI_CONTROL\[0\]](#) ENABLE bit reset to 0x0

The RFBI_DISPC_STALL signal is deasserted when the DSS.[RFBI_CONTROL\[0\]](#) ENABLE bit is set to 0x1 and at least one of the following cases occur:

- Low FIFO threshold reached
- External TE occurs and the DSS.[RFBI_CONFIG\[3:2\]](#) TRIGGERMODE bit field is set to 0x1 or 0x2 for automatic external trigger (start of the transfer, the FIFO pointers are reset, the FIFO is empty).
- DSS.[RFBI_CONTROL\[4\]](#) ITE bit set to 0x1 by users (start of the transfer, the FIFO pointers are reset, the FIFO is empty).

7.5.7.2.6 Number of Pixels to Transfer

Setting the DSS.[RFBI_PIXEL_CNT\[31:0\]](#) PIXELCNT bit field value directs the application to indicate the number of pixels to be transferred to the LCD panel. The value can be changed only when the DSS.[RFBI_CONTROL\[0\]](#) ENABLE is reset.

During the transfer, the hardware decrements the register when a pixel is sent to the remote frame buffer. When the DSS.[RFBI_CONTROL\[0\]](#) ENABLE bit is set and a new value is written in the DSS.[RFBI_PIXEL_CNT](#) register when the current value in the register is a non-zero (the remaining number of pixels to transfer), the ongoing transfer is aborted.

From the L4 interconnect side, if the DSS.[RFBI_CONFIG\[10:9\]](#) CYCLEFORMAT bit field is equal to 0x3 and the DSS.[RFBI_CONFIG\[8:7\]](#) L4FORMAT bit field is equal to 0x0, an even number of write accesses to the data register must be performed before accessing any other register (CMD/PARAM/STATUS/READ).

When the DSS.[RFBI_CONFIG\[10:9\]](#) CYCLEFORMAT bit field is 0x3 (2 pixels are sent over 3 cycles), the number of pixels to be programmed in the DSS.[RFBI_PIXEL_CNT\[31:0\]](#) PIXELCNT bit field must be a multiple of 2. If another CYCLEFORMAT is used, the value for PIXELCNT can be odd or even. This constraint is valid for data provided on the L4 interconnect port and from the display controller.

If the DSS.[RFBI_CONFIG\[10:9\]](#) CYCLEFORMAT bit field is equal to 0x3, the DSS.[RFBI_CONFIG\[8:7\]](#) L4FORMAT bit field is equal to 0, and back-to-back register write is processed. The following registers should be written after the first data: [RFBI_CMD](#), [RFBI_PARAM](#), [RFBI_READ](#), and [RFBI_STATUS](#). The whole data transfer must first be performed before being able to write to any other registers ([RFBI_CMD](#), [RFBI_PARAM](#), [RFBI_READ](#), and [RFBI_STATUS](#)).

7.5.7.2.7 Programmable Line Number

When the trigger mode is set to external trigger mode with HSYNC and VSYNC or the TE, hardware resets the line counter when the VSYNC occurs and, after a programmable number of lines (the HSYNC pulse occurs for every line), the transfer to the LCD panel begins. When the programmable line number is 0, only the VSYNC pulse indicates the beginning of the transfer in both modes: HSYNC/VSYNC and TE (logical OR operation between HSYNC and VSYNC).

7.5.7.3 RFBI Configuration

The following registers define the RFBI configuration:

- DSS.RFBI_SYSCONFIG
- DSS.RFBI_SYSSTATUS
- DSS.RFBI_CONFIG0 (configuration 0) and DSS.RFBI_CONFIG1 (configuration 1)
- DSS.RFBI_VSYNC_WIDTH
- DSS.RFBI_HSYNC_WIDTH

The configuration register for one configuration can be accessed only when the configuration is not in use (based on the value of the [RFBI_CONTROL\[3:2\]](#) CONFIGSELECT bit field).

7.5.7.3.1 Parallel Mode

The DSS.RFBI_CONFIG*i*[1:0]PARALLELMODE bit field (where *i* = 0, 1) defines the width of the interface (8-, 9-, 12-, or 16-bit parallel).

7.5.7.3.2 Trigger Mode

Setting the DSS.RFBI_CONFIG[3:2]TRIGGERMODE bit field configures the trigger on the external TE signal (RFBI_TE_VSYNC), or external with VSYNC/HSYNC with the programmable number of HSyncs to begin the transfer in both cases or the internal programmable DSS.RFBI_CONTROL[4] ITE bit.

7.5.7.3.3 VSYNC Pulse Width (Minimum Value)

The DSS.RFBI_VSYNC_WIDTH[15:0] MINVSYNCPULSEWIDTH bit field defines the minimum number of L4 clock cycles of the VSYNC pulse for detection on VSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal and is also used in the VSYNC/HSYNC mode on the two separate input lines.

- The VSYNC pulse width must be at least equal to two L4 cycles when HSYNC is not present.
- The VSYNC pulse width must be at least equal to four L4 cycles when HSYNC is present.

7.5.7.3.4 HSYNC Pulse Width (Minimum Value)

The DSS.RFBI_HSYNC_WIDTH[15:0] MINHSYNCPULSEWIDTH bit field defines the minimum number of L4 clock cycles of the HSYNC pulse for detection on HSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal, and is also used in the VSYNC/HSYNC mode on the two separate two input lines. The HSYNC pulse width must always be at least equal to two L4 cycles to be detected.

7.5.7.3.5 Cycle Format

Setting the DSS.RFBI_CONFIG*i*[10:9] CYCLEFORMAT bit field (with *i* = 0, 1) defines which registers are used to format the data in the interconnect FIFO with the appropriate number of bits (starting from the LSB) and with the alignment on the interface as follows:

- DSS.RFBI_DATA_CYCLE_*i* (if DSS.RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 00) only or
- DSS.RFBI_DATA_CYCLE1_*i* and DSS.RFBI_DATA_CYCLE2_*i* (if DSS.RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 01)
or
- DSS.RFBI_DATA_CYCLE1_*i*, DSS.RFBI_DATA_CYCLE2_*i*, and DSS.RFBI_DATA_CYCLE3_*i* (if DSS.RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 10)

The data from the display controller and from the L4 interconnect are formatted based on the configuration of the DSS.RFBI_DATA_CYCLE_*i* registers.

7.5.7.3.6 Unused Bits

Based on the configuration, the undefined bits for each cycle are defined with the previous values of the bits at the same position in the previous cycle, 0s, or 1s (the unused bits can be at any position). The DSS.RFB_i_CONFIG[12:11] UNUSEDBITS bit field (with $i = 0, 1$) is used.

7.5.7.3.7 RFBI Timings

The timing registers for one configuration can be accessed only when the configuration is not in use (based on the value of the DSS.RFB_i_CONTROL[3:2] CONFIGSELECT bit field). Granularity is defined using the DSS.RFB_i_CONFIG[4] TIMEGRANULARITY bit. This feature allows the extension of programmable ranges of timing parameters for the RFBI interface. Refer to [Table 7-72](#) for the bits configuration values.

- Chip-select assertion/deassertion time

RFBI_A0 setup time to chip-select assertion is assured by the programmable chip-select assertion time from the start access time:

DSS.RFB_i_ONOFF_TIME[3:0] CSONTIME bit field (with $i = 0, 1$).

The chip-select deassertion time from the start access time is programmable:

DSS.RFB_i_ONOFF_TIME[9:4] CSOFTTIME bit field (with $i = 0, 1$)

CAUTION

Configuring DSS.RFB_i_ONOFF_TIME[3:0] CSONTIME = DSS.RFB_i_ONOFF_TIME[9:4] CSOFTTIME = 0 (with $i = 0, 1$) is not supported and must be avoided. This configuration creates contention on the bus and progressively damages the LCD panel.

- Chip-select pulse width

The total chip-select pulse width is the time when write cycle time or read cycle time has completed and is programmable:

DSS.RFB_i_CYCLE_TIME[17:12] CSPULSEWIDTH bit field (with $i = 0, 1$)

It applies on the read-to-write, write-to-read, read-to-read, and write-to-write access based on:

- The DSS.RFB_i_CYCLE_TIME[19] RRENABLE bit: Read-to-read access
- The DSS.RFB_i_CYCLE_TIME[20] WWENABLE bit: Write-to-write access
- The DSS.RFB_i_CYCLE_TIME[18] RWENABLE bit: Read-to-write access
- The DSS.RFB_i_CYCLE_TIME[21] WRENABLE bit: Write-to-read access

By default, it applies to any access (read-to-read, read-to-write, write-to-read, write-to-write) when the chip-select changes.

- Access time

The total access time is the time from when A0 becomes valid until data are sampled before deasserting the RE signal; access time is programmable:

DSS.RFB_i_CYCLE_TIME[27:22] ACESSTIME bit field (with $i = 0, 1$)

When reading the data on the bus, the data are sampled at the end of the access time, which occurs before the end of the read off time (DSS.RFB_i_ONOFF_TIME[29:24] REOFFTIME, with $i = 0, 1$).

- Write enable cycle time

The total write enable cycle time is the time from when A0 becomes valid until write cycle completion; the write enable cycle time is programmable:

The DSS.RFB_i_CYCLE_TIME[5:0] WECYCLETIME bit field (with $i = 0, 1$)

- Write enable assertion/deassertion time

The WE assertion delay time from start access time is programmable:

DSS.RFB_i_ONOFF_TIME[13:10] WEONTIME bit field (with $i = 0, 1$)

The WE deassertion delay time from the start access time is programmable:

DSS.RFB_i_ONOFF_TIME[19:14] WEOFETIME bit field (with $i = 0, 1$)

- Read enable cycle

The total read enable cycle time is the time when A0 becomes valid until read cycle completion; the read enable cycle time is programmable:

The DSS.RFBI_CYCLE_TIME_i[11:6] RECYCLETIME bit field (with i = 0, 1)

- Read enable assertion/deassertion time

The RE assertion delay time from the start access time is programmable:

DSS.RFBI_ONOFF_TIME_i[23:20] REONTIME bit field (with i = 0, 1)

The RE deassertion delay time from the start access time is programmable:

DSS.RFBI_ONOFF_TIME_i[29:24] REOFFTIME bit field (with i = 0, 1)

At cycle time completion (read access or write access) all control signals (RFBI_CS_i, RFBI_WR, and RFBI_RD, with i = 0, 1) are deasserted regardless of their deassertion time parameter values, if they are not deasserted already.

However, an exception to this forced deassertion exists when a pipelined request to the same chip-select or to a different chip-select is pending. Also, a control signal with deassertion time parameters equal to the cycle time parameter is not necessarily deasserted when a pipelined request to the same chip-select or different chip-select is pending. This prevents any unnecessary glitch transitions.

If no inactive cycles are required between successive accesses to the same chip-select (the DSS.RFBI_CYCLE_TIME_i[17:12] CSPULSEWIDTH bit field = 0, with i = 0, 1), and if assertion time parameters associated with the following access equal 0, the asserted control signals (RFBI_CS_i, RFBI_WR, and RFBI_RD, with i = 0, 1) stay asserted. This is applicable to any read/write-to-read/write access combination.

[Table 7-72](#) summarizes the configurations values for each timing bit.

Table 7-72. RFBI Timings Configuration

Configuration bits ⁽¹⁾	Granularity ⁽²⁾	
	one	two
DSS.RFBI_ONOFF_TIME _i [3:0] CSONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIME _i [9:4] CSOFTTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIME _i [17:12] CSPULSEWIDTH	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIME _i [27:22] ACESSTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIME _i [5:0] WECYCLETIME	0 to 63	0 to 126
DSS.RFBI_ONOFF_TIME _i [13:10] WEONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIME _i [19:14] WEOFETIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIME _i [11:6] RECYCLETIME	0 to 63	0 to 126
DSS.RFBI_ONOFF_TIME _i [23:20] REONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIME _i [29:24] REOFFTIME	0 to 63	0 to 126

⁽¹⁾ Where i = 0 or 1.

⁽²⁾ Number of L4Clk cycles. The granularity can be configured using the DSS.RFBI_CONFIG[4] TIMEGRANULARITY bit.

7.5.7.3.8 RFBI State-Machine

Referring to [Table 7-39](#), the signals RFBI_A0, RFBI_RD, and RFBI_WR are asserted/deasserted based on the register accessed (DSS.RFBI_CMD, DSS.RFBI_PARAM, DSS.RFBI_DATA, DSS.RFBI_READ, and DSS.RFBI_STATUS). When the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware, any access to the registers is stalled, except for the [RFBI_DATA](#) register.

The DSS.RFBI_SYSSTATUS[9] BUSYRFBIDATA bit indicates whether there are still pending data in the interconnect FIFO associated with the register [RFBI_DATA](#) only.

- Command register

Write a command at a time by writing in the DSS.RFBI_CMD register. If the previous command is not processed, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware and the access to writing a new command is stalled.

- Parameter register

Write a parameter at a time by writing in the DSS.[RFBI_PARAM](#) register.

If the previous parameter is not processed, the DSS.[RFBI_SYSSTATUS\[8\]](#) BUSY bit is set by hardware and the access to writing a new parameter is stalled.

- Data register

Write one or two pixels at a time by writing in the [RFBI_DATA](#) register (when DSS.[RFBI_CONFIG\[i\]\[10:9\]](#) CYCLEFORMAT = 0x3 with i = 0, 1, two pixels must be written contiguously, no other access to RFBI registers except DSS.[RFBI_DATA](#) is allowed).

The pixels are formatted based on the specified cycle format. If two pixels are written into the 32-data register, the DSS.[RFBI_CONFIG\[i\]\[8:7\]](#) L4FORMAT bit field indicates the number of pixels for each L4 access to the register and the order of the pixels

If the previous data are not processed, the DSS.[RFBI_SYSSTATUS\[8\]](#) BUSY bit is set by hardware and any access for writing new data is stalled. When the DSS.[RFBI_SYSSTATUS\[8\]](#) BUSY bit is reset by hardware, the access is not stalled.

- Read/status register

Send through the command and parameter registers the correct information to receive data in the data or status register. The read data from the LCD panel is initiated by writing into the DSS.[RFBI_READ](#) or DSS.[RFBI_STATUS](#) registers. In this case, the DSS.[RFBI_SYSSTATUS\[8\]](#) BUSY bit is set until the data are available in the register.

When the DSS.[RFBI_SYSSTATUS\[8\]](#) BUSY bit is set by hardware, the read or write access is stalled until the register is updated with a new value from the LCD panel. To avoid the stall, the software can poll the DSS.[RFBI_SYSSTATUS\[8\]](#) BUSY bit until it is reset by hardware. To receive the data, send the appropriate command/parameters.

7.5.7.3.9 RFBI Configuration Flow Charts

The RFBI configuration depends on the trigger mode used by the application. The available trigger modes are:

- Internal trigger mode when setting the DSS.[RFBI_CONFIG\[i\]\[3:2\]](#) TRIGGERMODE bit field to 0x0
- External trigger mode:
 - TE external trigger mode when setting the DSS.[RFBI_CONFIG\[i\]\[3:2\]](#) TRIGGERMODE bit field to 0x1
 - HSYNC/VSYNC external trigger mode when setting the DSS.[RFBI_CONFIG\[i\]\[3:2\]](#) TRIGGERMODE bit field to 0x2

[Figure 7-144](#) gives an example of how to program and use the RFBI module:

Figure 7-144. How to Use RFBI

dss-192

[Figure 7-145](#) details how to configure the RFBI registers:

Figure 7-145. RFBI Initial Configuration

dss-193

Figure 7-146 describes how to enable the RFBI module.

Figure 7-146. RFBI Output Enable

dss-324

7.5.8 Video Encoder Basic Programming Model

7.5.8.1 Video Encoder Software Reset

By setting the DSS.VENC_F_CONTROL[8] RESET bit to 1, the video encoder is reset. This bit is automatically cleared by hardware when the reset is done.

NOTE: Before changing the standard (NTSC or PAL) and all the related registers, a software reset is required to properly initialize the VENC module.

7.5.8.2 Video DAC Stage Settings

The video output format can be either:

- one composite video (CVBS) output signal with video DAC1 or

- two separated luma/chroma output signals with both video DAC1(luma analog signal) and DAC2(chroma analog signal)

Selection is performed with DSS.DSS_CONTROL[6] VENC_OUT_SEL bit:

- When VENC_OUT_SEL bit is set to 0 (reset value), video DAC1 is selected for composite video (CVBS) signal
- When VENC_OUT_SEL bit is set to 1, video DAC1 is selected for luma signal

One of the first VENC settings is to enable the outputs of the video DACs. This setting depends on the video output format:

- CVBS video output format: Enable video DAC1 composite output by setting the DSS.VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE bit to 1
- Separated luma/chroma output format: Enable video DAC1 luma output by setting the DSS.VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit to 1 and enable video DAC2 chroma output by setting the DSS.VENC_OUTPUT_CONTROL[2] CHROMA_ENABLE bit to 1

Table 7-73 shows different configurations for the analog TV output, along with the respective values to be set in the dedicated registers inside the device system control module.

Table 7-73. Analog TV Output Modes

Analog TV output modes				
Control Register	Composite DC-coupled mode, high full scale	Composite AC-coupled mode, low full scale	S-Video DC-coupled mode, high full scale	Bypass mode, dual channels

CONTROL.CONTROL_AVDAC2 [16] AVDAC2_COMP_EN	0: External current reference	0: External current reference	0: External current reference	0: External current reference

7.5.8.3 Video Encoder Programming Sequence

1. Set the DSS.VENC_F_CONTROL[8] RESET bit to 1 to perform a software reset of the VENC module.
2. Before any configuration change, save the DSS.DISPC_IRQENABLE register value (DSS interrupts context), and then disable the display subsystem interrupts by setting the DSS.DISPC_IRQENABLE register to 0x0000.
3. Configure the video encoder registers as described in [Table 7-74](#), depending on the video standard used (PAL or NTSC). The DSS.VENC_F_CONTROL and DSS.VENC_SYNC_CTRL registers must be the last ones to be changed by software.
4. Set the DSS.DISPC_CONTROL[6] GODIGITAL bit and the DSS.DISPC_CONTROL[1] DIGITALENABLE bit to 1.
5. Wait for the first VSYNC pulse signal.
6. Clear the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit to 1.
7. Set the DSS.DISPC_IRQENABLE register to the value saved in step 2 (restore the DSS interrupts context).

7.5.8.4 Video Encoder Register Settings

For video encoder programming, see [Table 7-74](#). This table lists the register values to use in standard applications. These values are validated programming values only for the TV display support (NTSC 601 and PAL 601 standards).

Table 7-74. Video Encoder Register Programming Values

Register Name	NTSC 601	PAL 601
VENC_F_CONTROL	0x00000000	0x00000000

VENC_OUTPUT_TEST	0x00000000	0x00000000

NOTE: The following display controller registers must be programmed to the NTSC 601 video standard:

DSS.DISPC_SIZE_DIG[10:0] PPL = $720 - 1 = 719 = 0x2CF$

DSS.DISPC_SIZE_DIG[26:16] LPP = $(482/2) - 1 = 240 = 0xF0$

DSS.DISPC_GFX_BA0 or DSS.DISPC_VIDn_BA0 = Base address of even bit field data

DSS.DISPC_GFX_BA1 or DSS.DISPC_VIDn_BA1 = Base address of odd bit field data

7.6 Display Subsystem Use Cases and Tips

This section gives some generic use cases and tips for setting the modules of the display subsystem.

7.6.1 How to Configure the Scaling Unit in the DISPC Module

This section describes the scaling capability of the display controller (DISPC). The scaling unit is a part of the video pipeline used when transferring pixels from the system memory (SDRAM or on-chip SRAM) to the LCD panel or the TV set. The scaling unit consists of two scaling blocks: The vertical scaling block followed by the horizontal scaling block. The input pixel format is RGB24. In case the pixel format in system memory is not RGB, the color space conversion unit in front of the scaling unit converts the YUV pixels into RGB pixels. The two scaling units are independent: Neither of them, only one, or both can be used simultaneously.

7.6.1.1 Filtering

The scaling is used to down-scale, up-scale, or process the image while keeping the same size. It is applied independently horizontally and vertically. The same filtering applies for each color component (R, G, or B).

7.6.1.1.1 Vertical Filtering

The vertical filtering unit is based on a poly-phase rotation architecture with eight phases and three taps. That means that 24 coefficients are programmable.

The vertical 3-tap filtering macro architecture is shown in Figure 7-147.

Figure 7-147. Vertical Filtering Macro Architecture (Three Taps)

dss-112

For the 3-tap vertical up/downsampling the equation is (with the example of R component):

$$Rout(n) = \left(\sum_{i=-1}^{i=1} C_i(\Phi) \times Rin(n+i) \right) >> 7 \quad (14)$$

ds-E067

Legend:

Rout: R component output
 $C_i()$:Vertical FIR coefficients
 Rin: R component input
 The line (n+1) is older than line (n).

NOTE: If the 5-tap resizer is used for RGB16 and YUV4:2:2 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS == 1

DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX 4 and even

The programmable three coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient $C_0()$, which is unsigned).

The vertical filtering unit can be configured to support five taps.

The vertical 5-tap filtering macro architecture is shown in [Figure 7-148](#).

Figure 7-148. Vertical Filtering Macro Architecture (Five Taps)

dss-113

For the 5-tap vertical up/downsampling the equation is (with the example of R component):

$$\text{Rout}(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times \text{Rin}(n+i) \right) \gg 7 \quad (15)$$

dss-E066

Legend:

Rout: R component output
 $C_i()$:Vertical FIR coefficients with $C_{+2}()=C_{00}()$ and $C_{-2}()=C_{22}()$
 Rin: R component input
 The line (n+1) is older than line (n).

The programmable five coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient $C_0()$, which is unsigned).

In case of three taps, the memory lines are merged into three lines instead of six lines (one line is used as a cache line).

The first line is duplicated to fill up the two first lines (3-tap configuration) and the three first lines (5-tap configuration).

The last line is duplicated if the scaling logic requires loading of more lines and the last line has been reached

7.6.1.1.2 Horizontal Filtering

The horizontal filtering unit is based on a poly-phase rotation architecture with eight phases and five taps. That means that 40 coefficients are programmable.

The horizontal filtering macro architecture is shown in [Figure 7-149](#).

Figure 7-149. Horizontal Filtering Macro Architecture (Five Taps)

dss-114

For the 5-tap horizontal up/downsampling, the equation is (with the example of R component):

$$Rout(n) = \left(\sum_{i=-3}^{i=3} C_i(\Phi) \times Rin(n+i) \right) \gg 7$$

dss-E115 (16)

Legend:

Rout: R component output

Ci(): Vertical FIR coefficients

Rin: R component input

The line (n+1) is older than line (n).

To horizontally and vertically filter the video layer, the phase is calculated separately. The programmable coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient $C_0()$, which is unsigned).

The first pixel is duplicated to fill up the three first pixel-buffers (5-tap configuration). The last pixel is duplicated if the scaling logic requires loading of more pixels and the last pixel has been reached

7.6.1.2 Scaling Algorithms

The up/downsampling finite state machines (FSM) below are detailed in this section.

[Figure 7-150](#) presents the vertical up/downsampling FSM.

Figure 7-150. Vertical Up-/Down-Sampling Algorithm

dss-116

Figure 7-151 presents the horizontal up/downsampling FSM.

Figure 7-151. Horizontal Up-/Down-Sampling Algorithm

dss-117

7.6.1.3 Scaling Settings

NOTE:

- In this section, the screen word refers to LCD panel or TV set.
- n indicates pipeline 0 or 1 because there are two video pipelines in the DISPC.

7.6.1.3.1 Register List

The following registers define the scaling registers for the video layer n configuration:

- DSS.DISPC_VIDn_BAj
- DSS.DISPC_VIDn_ATTRIBUTES
- DSS.DISPC_VIDn_FIR
- DSS.DISPC_VIDn_ACCUI
- DSS.DISPC_VIDn_FIR_COEF_Hi
- DSS.DISPC_VIDn_FIR_COEF_HVi
- DSS.DISPC_VIDn_FIR_COEF_Vi

Table 7-75 lists the registers for programming the vertical FIR coefficients (3-tap configuration).

Table 7-75. Vertical FIR Coefficients Corresponding Table (3-Tap Configuration)

$C_x()$	VidFIRVC _x ()
$C_{-1}()$	VidFIRVC ₂ ()
$C_0()$	VidFIRVC ₁ ()

Table 7-75. Vertical FIR Coefficients Corresponding Table (3-Tap Configuration) (continued)

$C_x()$	$\text{VidFIRVC}_x()$
$C_1()$	$\text{VidFIRVC}_1()$

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- $\text{VidFIRVC}_2() = \text{DSS.DISPC_VIDn_FIR_COEF_HVi}[31:24]$ VIDFIRVC2
- $\text{VidFIRVC}_1() = \text{DSS.DISPC_VIDn_FIR_COEF_HVi}[23:16]$ VIDFIRVC1
- $\text{VidFIRVC}_0() = \text{DSS.DISPC_VIDn_FIR_COEF_HVi}[15:8]$ VIDFIRVC0

Table 7-76 lists the registers for programming the vertical FIR coefficients (5-tap configuration).

Table 7-76. Vertical FIR Coefficients Corresponding Table (5-Tap Configuration)

$C_x()$	$\text{VidFIRVC}_x()$
$C_{22}()$	$\text{VidFIRVC}_{22}()$
$C_{-1}()$	$\text{VidFIRVC}_{-1}()$
$C_0()$	$\text{VidFIRVC}_0()$
$C_1()$	$\text{VidFIRVC}_1()$
$C_{00}()$	$\text{VidFIRVC}_{00}()$

The corresponding registers for programming the vertical FIR coefficients (5-tap configuration) are:

- $\text{VidFIRVC}_{22}() = \text{DSS.DISPC_VIDn_FIR_COEF_Vi}[15:8]$ VIDFIRVC22
- $\text{VidFIRVC}_2() = \text{DSS.DISPC_VIDn_FIR_COEF_HVi}[31:24]$ VIDFIRVC2
- $\text{VidFIRVC}_1() = \text{DSS.DISPC_VIDn_FIR_COEF_HVi}[23:16]$ VIDFIRVC1
- $\text{VidFIRVC}_0() = \text{DSS.DISPC_VIDn_FIR_COEF_HVi}[15:8]$ VIDFIRVC0
- $\text{VidFIRVC}_{00}() = \text{DSS.DISPC_VIDn_FIR_COEF_Vi}[7:0]$ VIDFIRVC00

Table 7-77 lists the registers for programming the horizontal FIR coefficients (5-tap configuration).

Table 7-77. Horizontal FIR Coefficients Corresponding Table (5-Tap Configuration)

$C_x()$	$\text{VidFIRHC}_x()$
$C_{-2}()$	$\text{VidFIRHC}_{-4}()$
$C_{-1}()$	$\text{VidFIRHC}_{-3}()$
$C_0()$	$\text{VidFIRHC}_2()$
$C_1()$	$\text{VidFIRHC}_1()$
$C_2()$	$\text{VidFIRHC}_0()$

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- $\text{VidFIRHC}_4() = \text{DSS.DISPC_VIDn_FIR_COEF_HVi}[7:0]$ VIDFIRHC4
- $\text{VidFIRHC}_3() = \text{DSS.DISPC_VIDn_FIR_COEF_HVi}[31:24]$ VIDFIRHC3
- $\text{VidFIRHC}_2() = \text{DSS.DISPC_VIDn_FIR_COEF_HVi}[23:16]$ VIDFIRHC2
- $\text{VidFIRHC}_1() = \text{DSS.DISPC_VIDn_FIR_COEF_HVi}[15:8]$ VIDFIRHC1
- $\text{VidFIRHC}_0() = \text{DSS.DISPC_VIDn_FIR_COEF_HVi}[7:0]$ VIDFIRHC0

7.6.1.3.2 Enabling

The video pipeline #n is enabled/disabled by setting/resetting the $\text{DSS.DISPC_VIDn_ATTRIBUTES}[0].\text{VIDENABLE}$ bit. While the video pipeline is enabled/disabled, the video layer is visible/not visible on the screen (LCD panel or TV set).

The video up/downsampling block for the video pipeline #n is programmed by setting the DSS.DISPC_VIDn_ATTRIBUTES[6:5] VIDRESIZEENABLE bit field:

- When the VIDRESIZEENABLE[1] bit is set to 1, the video vertical up/downsampling block is enabled. When set to 0, the vertical resize processing is disabled.
- When the VIDRESIZEENABLE[0] bit is set to 1, the video horizontal up/downsampling block is enabled. When set to 0, the horizontal resize processing is disabled.
- When the VIDRESIZEENABLE[1:0] is set to 0x3, both horizontal and vertical resize processing are enabled.

NOTE:

- Set a valid configuration before enabling the video up/downsampling block.
 - Vertical and horizontal downsampling are limited to a 0.25 resize factor. When processing a down-scaling with a vertical factor between 0.5 and 0.25, a 5-tap filter configuration must be used. See [Section 7.6.1.3.5](#) for more information concerning the filter coefficients.
-

7.6.1.3.3 Factor

The following register bit fields define the increment value of the video up/downsampling block for video pipeline n:

- Vertical up/downsampling increment value (DSS.DISPC_VIDn_FIR[27:16] VIDFIRVINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRVINC}[11:0] = 1024 \times \frac{\text{VIDORGSIZEY}[10:0]}{\text{VIDSIZEY}[10:0]} \quad \text{dss-E118} \quad (17)$$

NOTE:

- If the VIDFIRVINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEY[10:0] equals 0x1, VIDSIZEY[10:0] is replaced by 0x2 in the previous equation.
- The VIDORGSIZEY[10:0] and VIDSIZEY[10:0] bit field values must be programmed with the value desired minus 1.
- Horizontal up/downsampling increment value (the DSS.DISPC_VIDn_FIR[11:0] VIDFIRHINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRHINC}[11:0] = 1024 \times \frac{\text{VIDORGSIZEX}[10:0]}{\text{VIDSIZEX}[10:0]} \quad \text{dss-E119} \quad (18)$$

NOTE:

- If the VIDFIRHINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEX[10:0] equals 1, VIDSIZEX[10:0] is replaced by 2 in the previous equation.
 - The VIDORGSIZEX[10:0] and VIDSIZEX[10:0] bit field values must be programmed with the value desired minus 1.
-

7.6.1.3.4 Initial Phase

- Vertical up/downsampling accumulator value DSS.DISPC_VIDn_ACCU[25:16] VIDVERTICALACCU bit fields

The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the vertical filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data.

- Vertical up/downsampling accumulator value DSS.DISPC_VIDn_ACCU[9:0] VIDHORIZONTALACCU

bit fields

The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the horizontal filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data

Table 7-78 lists the vertical/horizontal accumulator values and phases

Table 7-78. Vertical/Horizontal Accumulator Phase

Accumulator Value	Phases
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

NOTE: For LCD output, the initial phase is always 0 (horizontal and vertical.) For TV output, the vertical phases (odd and even) can be nonzero values.

7.6.1.3.5 Coefficients

- Vertical up/downsampling coefficients ([DSS.DISPC_VIDn_FIR_COEF_HVi](#) and [DSS.DISPC_VIDn_FIR_COEF_V](#))

The 3-tap vertical up/downsampling coefficients are defined in DSS.[DISPC_VIDn_FIR_COEF_HVi](#) registers. There are eight registers for the eight phases with three coefficients for each of them so a total of 24 programmable coefficients for the vertical up/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (central one).

In addition, there are 2-tap vertical up/downsampling coefficients defined in DSS.[DISPC_VIDn_FIR_COEF_Vi](#) registers. There are eight registers for the eight phases with two coefficients for each of them so a total of 16 programmable coefficients for the vertical up/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients ($C_{22}()$ and $C_{00}()$).

In case of 5-tap configuration, both sets of registers, DSS.[DISPC_VIDn_FIR_COEF_HVi](#) and DSS.[DISPC_VIDn_FIR_COEF_V](#), are used. In case of 3-tap configuration, only one set of registers, DSS.[DISPC_VIDn_FIR_COEF_HV](#), is used.

- Horizontal up/downsampling coefficients ([DSS.DISPC_VIDn_FIR_COEF_Hi](#) and [DSS.DISPC_VIDn_FIR_COEF_HV](#))

The 5-tap horizontal up/downsampling coefficients are defined in DSS.[DISPC_VIDn_FIR_COEF_Hi](#) and DSS.[DISPC_VIDn_FIR_COEF_HVi](#) registers. There are eight registers for the eight phases with five coefficients for each register, for a total of 40 programmable coefficients for the horizontal up/downsampling block.

Each DSS.[DISPC_VIDn_FIR_COEF_Hi](#) register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (central one), and each DSS.[DISPC_VIDn_FIR_COEF_HVi](#) contains one 8-bit signed coefficient.

Table 7-79 through Table 7-84 give the programmable coefficients for the FIR up/downsampling filters (Max-Fauque-Berthier method).

7.6.1.3.5.1 Up-Sampling

Table 7-79 gives the 24 coefficients to program the vertical upsampling (3-tap configuration).

Table 7-79. Up-Sampling Vertical Filter Coefficients (Three Taps)

Phases	VidFIRVC ₂ ()	VidFIRVC ₁ ()	VidFIRVC ₀ ()
0	0	128	0
1	3	123	2
2	12	111	5
3	32	89	7
4	0	64	64
5	7	89	32
6	5	111	12
7	2	123	3

Table 7-80 gives the 40 coefficients to program the vertical upsampling (5-tap configuration).

Table 7-80. Up-Sampling Vertical Filter Coefficients (Five Taps)

Phases	VidFIRVC ₂₂ ()	VidFIRVC ₂ ()	VidFIRVC ₁ ()	VidFIRVC ₀ ()	VidFIRVC ₀₀ ()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1
3	-5	51	95	-11	-2
4	0	-9	73	73	-9
5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

Table 7-81 gives the 40 coefficients to program the horizontal upsampling (5-tap configuration).

Table 7-81. Up-Sampling Horizontal Filter Coefficients (Five Taps)

Phases	VidFIRHC ₄ ()	VidFIRHC ₃ ()	VidFIRHC ₂ ()	VidFIRHC ₁ ()	VidFIRHC ₀ ()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1
3	-5	51	95	-11	-2
4	0	-9	73	73	-9
5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

The upsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x0D7CF800
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x037B02FF
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x1E70F5FF
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x0C6F05FE
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x335FF5FE
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x205907FB
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0xF74949F7
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x00404000

- DSS.DISPC_VIDn_FIR_COEF_H5 = 0xF55F33FB
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x075920FE
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0xF5701EFE
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x056F0CFF
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0xF87C0DFF
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x027B0300

NOTE: In this case, the DSS.DISPC_VIDn_FIR_COEF_Vi registers are not used.

The upsampling coefficients register configuration (both vertical and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_V0 = 0x00000000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x0D7CF800
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x0D7CF8FF
- DSS.DISPC_VIDn_FIR_COEF_V1 = 0x0000FF00
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x1E70F5FF
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x1E70F5FE
- DSS.DISPC_VIDn_FIR_COEF_V2 = 0x0000FEFF
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x335FF5FE
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x335FF5FB
- DSS.DISPC_VIDn_FIR_COEF_V3 = 0x0000FBFE
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0xF74949F7
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0xF7404000
- DSS.DISPC_VIDn_FIR_COEF_V4 = 0x000000F7
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0xF55F33FB
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0xF55F33FE
- DSS.DISPC_VIDn_FIR_COEF_V5 = 0x0000FEFB
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0xF5701EFE
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0xF5701EFF
- DSS.DISPC_VIDn_FIR_COEF_V6 = 0x0000FFFE
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0xF87C0DFF
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0xF87C0D00
- DSS.DISPC_VIDn_FIR_COEF_V7 = 0x000000FF

7.6.1.3.5.2 Down-Sampling

Table 7-82 gives the 24 coefficients to program the vertical downsampling (3-tap configuration).

Table 7-82. Down-Sampling Vertical Filter Coefficients (Three Taps)

Phases	VidFIRVC ₂ ()	VidFIRVC ₁ ()	VidFIRVC ₀ ()
0	36	56	36
1	40	57	31
2	45	56	27

5	-7	22	53	48	12
6	-5	27	54	44	8
7	-2	31	55	40	4

Table 7-84 gives the 40 coefficients to program the horizontal downsampling (5-tap configuration).

Table 7-84. Down-Sampling Horizontal Filter Coefficients (Five Taps)

Phases	VidFIRHC ₄ ()	VidFIRHC ₃ ()	VidFIRHC ₂ ()	VidFIRHC ₁ ()	VidFIRHC ₀ ()
0	0	36	56	36	0
1	4	40	55	31	-2
2	8	44	54	27	-5
3	-12	48	53	22	-7
4	-9	17	52	51	17
5	-7	22	53	48	12
6	-5	27	54	44	8
7	-2	31	55	40	4

The downsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x28371FFE
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x28391F04
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x2C361BFB
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x2D381B08
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x303516F9
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x3237170C
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0x11343311
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x123737F7
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0x1635300C
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x173732F9
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0x1B362C08
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x1B382DFB
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0x1F372804

-
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x1F3928FE
-

NOTE:

- In this case, the DSS.DISPC_VIDn_FIR_COEF_Vi registers are not used.
 - In this case, the downsampling factor must be higher than 1/2.
-

The downsampling coefficients register configuration (both the vertical and the horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x24382400
 - DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x24382400
 - DSS.DISPC_VIDn_FIR_COEF_V0 = 0x00000000
 - DSS.DISPC_VIDn_FIR_COEF_H1 = 0x28371FFE
 - DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x28371F04
 - DSS.DISPC_VIDn_FIR_COEF_V1 = 0x000004FE
 - DSS.DISPC_VIDn_FIR_COEF_H2 = 0x2C361BFB
 - DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x2C361B08
 - DSS.DISPC_VIDn_FIR_COEF_V2 = 0x000008FB
 - DSS.DISPC_VIDn_FIR_COEF_H3 = 0x303516F9
 - DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x3035160C
 - DSS.DISPC_VIDn_FIR_COEF_V3 = 0x00000CF9
 - DSS.DISPC_VIDn_FIR_COEF_H4 = 0x11343311
 - DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x113433F7
 - DSS.DISPC_VIDn_FIR_COEF_V4 = 0x0000F711
 - DSS.DISPC_VIDn_FIR_COEF_H5 = 0x1635300C
 - DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x163530F9
 - DSS.DISPC_VIDn_FIR_COEF_V5 = 0x0000F90C
 - DSS.DISPC_VIDn_FIR_COEF_H6 = 0x1B362C08
 - DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x1B362CFB
 - DSS.DISPC_VIDn_FIR_COEF_V6 = 0x0000FB08
 - DSS.DISPC_VIDn_FIR_COEF_H7 = 0x1F372804
 - DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x1F3728FE
 - DSS.DISPC_VIDn_FIR_COEF_V7 = 0x0000FE04
-

NOTE: This configuration must be used for vertical downsampling factors between 1/2 and 1/4

7.6.2 Display Low-Power Refresh Settings

This section describes the display low-power refresh application on the device. The display subsystem remains active while saving power by putting unused power domains and unused modules into idle mode. This process can be expanded to include the screen saver mode in which the MPU subsystem wakes up to update the frame buffer and then returns to idle mode. On the device platform, where power consumption is of high importance, the display modes must be configured properly to achieve optimal power savings

The display low-power refresh mode can be used in the following scenarios:

- During the period of time when there is no application running and the backlight turns off.
- Once the backlight turns off, the LCD display can be shut off or can be refreshed showing the time and date. The screen saver mode can be used to update the time every minute.

This section discusses the methodology for finding optimal power savings. These settings are detailed for a 16-bit, 240 x 320 pixel QVGA LCD.

7.6.2.1 Display Low-Power Refresh Overview

When the device is not in idle mode, meaning all clocks are on and the power is applied to all power domains, the following activity typically occurs with respect to the display subsystem:

- The MPU subsystem is processing
- The display subsystem DMA controller is moving data from the SDRAM frame buffer location to the display subsystem internal FIFO.
- The LCD data is being sent from the internal FIFO to the display panel.

When the MPU goes into idle mode, the following activity occurs:

- The display subsystem DMA controller remains active, moving data from the SDRAM frame buffer to the internal FIFO.
- The SDRAM will go in and out of self-refresh between transfers.
- The display subsystem internal FIFO will continue to send LCD data to the display panel.

This procedure is named as the display low-power refresh scenario.

NOTE: In the device, the display subsystem has its own power domain (the DSS power domain).

7.6.2.2 Display Subsystem Clock

7.6.2.2.1 Display Subsystem Clock Configuration

The display subsystem contains two possible functional clock sources, DSS functional clock 1 (DSS1_ALWON_FCLK) and DSI PLL functional clock 1 (DSI1_PLL_FCLK):

- DSS1_ALWON_FCLK is sourced from DPLL4 (DPLL4_ALWON_FCLK), with several multipliers available and is configured in the PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field.
- DSI1_PLL_FCLK is one of the two output clocks from the DSI PLL.

The pixel clock is set as either DSS1_ALWON_FCLK or DSI1_PLL_FCLK by configuring the DSS.[DSS_CONTROL\[0\]](#) DISPC_CLK_SWITCH bit

NOTE: When the DSI PLL is in bypass mode, the DSI1_PLL_FCLK clock is the DSS2_ALWON_FCLK clock. This ensures the backward compatibility with OMAP2 devices.

The LCD logic clock is determined by the DSS.[DISPC_DIVISOR\[23:16\]](#) LCD bit field. This divisor is used on the DSS functional clock that is selected in the [DSS_CONTROL](#) register (either DSS1_ALWON_FCLK or DSS2_ALWON_FCLK). This LCD divisor selects the logical clock frequency which is used to clock the logic in the display subsystem. For some applications there is a required minimum logical clock frequency. The lower the logical clock frequency then the lower the power consumption.

The pixel clock is determined by setting the DSS.[DISPC_DIVISOR\[7:0\]](#) PCD bit field. This divisor is used on the LCD logic clock.

In the following example, the DPLL4 clock (DPLL4_ALWON_FCLK) is enabled and running at 266 MHz:

The PRCM.CM_CLKSEL2_PLL[19:8] PERIPH_DPLL_MULT bit field is set to 0x4 and the PRCM.CM_CLKSEL2_PLL[6:0] PERIPH_DPLL_DIV bit field is set to 0x1 (DPLL4 x 4/(1+1)):

$$\text{DPLL4_ALWON_FCLKOUT} = \text{DPLL4_ALWON_FCLK}(266\text{MHz}) \times 4/2 = 532 \text{ MHz}$$

NOTE: The DPLL4_ALWON_FCLOUT clock is an internal clock in DPLL4 module after the DPLL_MULT and DPLL_DIV stages. The DPLL4_M4_CLK clock is one of the DPLL4 output clocks and is the clock source for DSS1_ALWON_FCLK.

The DSS.DSS_CONTROL[0] DSS_CLK_SWITCH bit is set to 0x0 to select DSS1_ALWON_FCLK as the display subsystem functional clock:

$$\text{DSS1_ALWON_FCLK} = \text{DPLL4_M4_CLK}$$

The PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field is set to 0x08:

$$\text{DSS1_ALWON_FCLK} = \frac{\text{DPLL4_ALWON_FCLKOUT (532MHz)}}{8} = 66.5 \text{ MHz}$$

dss-E120 (19)

The DSS.DISPC_DIVISOR[23:16] LCD bit field is set to 0x01:

$$\text{LogicClock} = \frac{\text{DSS1_ALWON_FCLK(66.5MHz)}}{1} = 66.5 \text{ Mhz}$$

dss-E121 (20)

The DSS.DISPC_DIVISOR[6:0] PCD bit field is set to 0x0C:

$$\text{PixelClock} = \frac{\text{LogicClock(66.5MHz)}}{12} = 5.54 \text{ Mhz}$$

dss-E122 (21)

7.6.2.2.1.1 Pixel Clock Frequency Settings to Reduce Power Consumption

Power consumption is reduced when a low pixel clock frequency is used. If the clock frequency is set too low, however, the frames-per-second (FPS) are reduced. This can result in visible flickering on the screen each time the screen is refreshed. To avoid electrical polarization problems, refer to the appropriate LCD panel datasheet to determine the maximum range of pixel clock frequency variation. To save power, therefore, the pixel clock frequency during low-power mode must be set as low as possible, but high enough to eliminate visible flickering

7.6.2.2.1.2 Display Subsystem Divider Settings to Reduce Power Consumption

The pixel clock is determined by the DSS.DISPC_DIVISOR[7:0] PCD and DSS.DISPC_DIVISOR[23:16] LCD settings. In most cases, the LCD[7:0] bit field is set to 0x1 and the PCD[7:0] bit field is used as the main divider. To reduce power consumption, software users should investigate if the DSS.DISPC_DIVISOR[23:16] LCD bit field can be set to a value other than 0x1 and then decrease DSS.DISPC_DIVISOR[7:0] PCD bit field value. For example, if the desired pixel clock is 1.625 MHz with a 13-MHz functional clock, then this pixel clock can be achieved by setting DSS.DISPC_DIVISOR[23:16] LCD to 0x1 and DSS.DISPC_DIVISOR[7:0] PCD to 0x8. The same pixel clock can be achieved by setting DSS.DISPC_DIVISOR[23:16] LCD to 0x2 and DSS.DISPC_DIVISOR[7:0] PCD to 0x4.

7.6.2.2.2 Display Subsystem Clock Enable

To take the DSS out of reset, all DSS-related clocks must be enabled, and the DPLL4 clock must be enabled. After taking the DSS out of reset, these clocks can be disabled if they are not used. The following clocks must be enabled before the DSS can come out of reset:

- PRCM.CM_FCLKEN_DSS[0] EN_DSS1 = 0x1
- PRCM.CM_FCLKEN_DSS[1] EN_DSS2 = 0x1
- PRCM.CM_FCLKEN_DSS[2] EN_TV = 0x1
- PRCM.CM_ICLKEN_DSS[0] EN_DSS = 0x1
- PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL = 0x7

Once these clocks are enabled, the display subsystem can be taken out of reset.

The following sections explain the display low-power mode configuration options, which are determined by product requirements (LCD panel type).

7.6.2.3 DPLL4 in Low-Power Mode

For optimal power savings in low-power mode, DPLL4 can be put into low-power stop mode. Thus the DSS1_ALWON_FCLK clock cut when DPLL4 is in low-power stop mode. Software users must switch from DSS1_ALWON_FCLK to DS1_PLL_FCLK by setting the DSS.[DSS_CONTROL\[0\]](#) DISPC_CLK_SWITCH bit to 0x1.

NOTE: Before switching to DS1_PLL_FCLK, the DSI PLL and the HS divider must be programmed and the DSI PLL must be locked.

DPLL4 can be put in low-power stop mode in either of the following methods:

- Manually: When setting the PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL bit to 0x1.
- Automatically: When setting the PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL bit field to 0x1. DPLL4 is automatically put in low-power stop mode when none of the 96- MHz and 54- MHz clocks are required anymore. DPLL4 is also restarted automatically.

Software users must remember to change the clock configuration after enabling DPLL4 when leaving low-power mode by setting the DSS.[DSS_CONTROL\[0\]](#) DISPC_CLK_SWITCH bit to 0x0. The DSS1_ALWON_FCLK clock will be selected.

Lock time must be considered before disabling the DSS1_ALWON_FCLK clock.

7.6.2.4 Autoidle and Smart Idle

7.6.2.4.1 Autoidle

To further save power consumption, the autoidle feature at the module can be enabled for the active modules. For example, the PRCM and the system control modules are active during this mode. By enabling the autoidle feature, the clocks at the module level are gated when they are not needed.

The RFBI, display controller, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.[DSS_SYSCONFIG\[0\]](#) AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.[RFBI_SYSCONFIG\[0\]](#) AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.[DISPC_SYSCONFIG\[0\]](#) AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.[DISPC_CONFIG\[9\]](#) FUNCATED bit (1: Functional clocks gated enabled, 0: Functional clocks gated disabled) for the display controller

7.6.2.4.2 Smart-Idle

The smart-idle feature can be enabled to allow the module to enter idle when the clocks are not needed. The smart-idle feature can be enabled for the display subsystem submodules to further save power consumption:

- Display subsystem: DSS.[DSS_SYSCONFIG\[4:3\]](#) SIDLEMODE
- Display controller: DSS.[DISPC_SYSCONFIG\[4:3\]](#) SIDLEMODE
- RFBI: DSS.[RFBI_SYSCONFIG\[4:3\]](#) SIDLEMODE

7.6.2.5 FIFO Thresholds

The display subsystem internal FIFO is used to move data to the LCD panel. This FIFO is filled by the display subsystem DMA controller. The DMA controller is triggered to start and stop based on two thresholds:

- DSS.[DISPC_GFX_FIFO_THRESHOLD\[11:0\]](#) GFXFIFOLOWTHRESHOLD
- DSS.[DISPC_GFX_FIFO_THRESHOLD\[27:16\]](#) GFXFIFOHIGHTHRESHOLD

When the level of the FIFO reaches the low threshold, the internal DMA controller begins to fill the FIFO With the data in the frame buffer. Once the amount of pixel data reaches the high threshold, the internal DMA controller stops.

7.6.2.5.1 FIFO Threshold Settings to Reduce Power Consumption

Power consumption is reduced by increasing the difference between the high and low FIFO threshold levels, thereby leaving the SDRAM in self-refresh for a longer period of time. To perform this reduction, consider the following:

- The low FIFO threshold level must be as low as possible, but not low enough to cause any underflow.
- The high FIFO threshold level must not exceed the FIFO size minus one burst. A value above this limit results in the DMA controller trying to fill the FIFO to a level that cannot be reached, which will increase power consumption.
- The difference between high and low FIFO threshold levels must not be less than one burst size. These settings do not reduce power consumption because the SDRAM never goes into self-refresh, but they will avoid underflow.

7.6.2.6 Vertical and Horizontal Timings

The vertical and horizontal timings and the pixel clock speed determine the number of frames updated per second. [Figure 7-152](#) shows the timings for a 240 x 320 pixel QVGA LCD panel. If the pulse width (also called blanking) and the front porch parameters are increased, more setup time is added before the data is transferred. This additional time is beneficial for delaying the data transfer if the data is not ready because of bandwidth limitations. Care must be taken to determine the fps when modifying these parameters.

Use the following formula to determine the fps for a 240 x 320 QVGA LCD:

$$f_{ps} = \frac{1}{[(Hsw + 1) + (Hfp + 1) + 240 + (Hbp + 1)] \times [(Vsw + 1) + Vfp + 320 + Vbp] \times (PCLK)}$$
dss-E123 (22)

With:

- Hsw: DSS.[DISPC_TIMING_H](#)[7:0] HSW bit field value
- Hfp: DSS.[DISPC_TIMING_H](#)[19:8] HFP bit field value
- Hbp: DSS.[DISPC_TIMING_H](#)[31:20] HBP bit field value
- Vsw: DSS.[DISPC_TIMING_V](#)[7:0] VSW bit field value
- Vfp: DSS.[DISPC_TIMING_V](#)[19:8] VFP bit field value
- Vbp: DSS.[DISPC_TIMING_V](#)[31:20] VBP bit field value
- PCLK: Pixel clock period

The horizontal (Hsw) and vertical (Vsw) pulse widths and the horizontal front (Hfp) and back (Hbp) porches are increased by 1 because the value is programmed as the desired value minus 1.

Figure 7-152. QVGA LCD Timings

dss-124

The fps for the example of 6-MHz pixel clock with the setting shown in [Figure 7-152](#) is as follows:

$$fps = \frac{1}{[(2+1) + 4 + 240 + 2] \times [(2+1) + 9 + 320 + 6] \times 166.67 \times 10^{-9}}$$

dss-E125

$$fps = 71.57\text{Hz}$$

(23)

7.6.2.6.1 Horizontal and Vertical Timing Settings to Reduce Power Consumption

The number of fps that the screen is refreshed is also determined by the vertical and horizontal timings. Consequently, longer timings between frames (blanking periods) reduce the fps and reduce average power consumption. Shorter blanking periods increase fps and increases power consumption. If the blanking between frames is too small, a FIFO underflow may occur.

7.6.3 How to Configure the DSI PLL in Video Mode

[Figure 7-153](#) shows a global overview of the DSI clock tree when used in video mode.

Figure 7-153. DSI Clock Tree in Video Mode

dss-300

The settings of the DSI PLL registers can be summarized by the following equations.

Equation 1

$$N * T_{VP_CLK} = T_L * T_{TxByteClkHS} \quad (24)$$

dss-301

where

$$T_L = T_{HS} + HSA_{DSI} + T_{HE} + HFP_{DSI} + (WC + 6)/NDL + HBP_{DSI}$$

N is an integer

NDL : Number of data lane

WC : Word count or payload in bytes

T_{HS} and T_{HE} are equal to $4/NDL$ and 0 if they are disabled.

HSA_{DSI} is HSA period in video mode.

T_{HS} is the length of HSYNC start short packet in number of byte clock cycles (TxByteClkHS).

T_{HE} is the length of HSYNC end short packet in number of byte clock cycles (TxByteClkHS).

HBP_{DSI} is HBP period in video mode.

HFP_{DSI} is HFP period in video mode.

NOTE: HSA_{DSI} timing is not used and does not have to be programmed when HE short packet is not generated.

Equation 2

$$R = T_{TxByteClkHS} / T_{VP_PCLK} \quad (25)$$

dss-302

To synchronize DISPC and DSI Protocol Engine, users should follow the ratio R between TxByteClkHS and VP_PCLK as listed in [Table 7-85](#).

Table 7-85. Ratio R

Number of data lanes	Pixel format	Ratio R
1	16-bits pixel	1/2
1	18-bits pixel	4/9
1	24-bits pixel	1/3
2	16-bits pixel	1
2	18-bits pixel	8/9
2	24-bits pixel	2/3

All cases are covered by:

$$F_{VP_PCLK} * bits_per_pixel = F_{TxByteClkHS} * NDL * 8 \quad (26)$$

dss-310

Equation 3

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * T_{VP_PCLK} = (4/NDL + HFP_{DSI} + (WC + 6)/NDL + HBP_{DSI}) * T_{TxByteClkHS} \quad (26)$$

dss-303

Equation 4

$$HFP_{DSI} = ((HFP_{DISPC} * bits_per_pixel) / (NDL * 8)) - (2 / NDL) \quad (27)$$

dss-309

Example

The desired performances are:

- Clock lane at 150 MHz
- RGB24-888

- 1-data lane
- LCD size 480*640 with $HSA_{DISP} = HFP_{DISP} = HBP_{DISP} = 20$, $VSA_{DISP} = VFP_{DISP} = VBP_{DISP} = 2$

Step 1. Determine REGM and REGN

To obtain correct stability, Fint must be kept between 0.032 MHz and 52 MHz . In this case, Fint is maintained at 2 MHz. For more information, see the DSI PLL programming model.

$$\text{REGN} = \left(\frac{F_{\text{DSI_PLL_REFCLK}}}{F_{\text{int}}} \right) - 1$$

$$\text{REGN} = 12$$

$$\text{REGM} = (\text{REGN} + 1) * F_{\text{CLKIN4DDR}} / (2 * F_{\text{DSI_PLL_REFCLK}})$$

$$\text{REGM} = 150$$

dss-318

Where $DSS2_ALWON_FCLK= 26$ MHz is used as a reference clock for $F_{\text{DSI_PLL_REFCLK}}$

Step 2. Determine VP_PCLK and TxByteClkHS clocks.

$TxByteClkHS$ frequency is equal to 37.5 MHz. With ratio R equal to 1/3, VP_PCLK frequency is equal to 12.5 MHz. The frame rate can be estimated by:

$$\text{Frame rate} = F_{\text{VP_PCLK}} / (HSA_{\text{DISPC}} + HFP_{\text{DISPC}} + PPL + HBP_{\text{DISPC}}) * (VSA_{\text{DISPC}} + VFP_{\text{DISPC}} + LPP + VBP_{\text{DISPC}})$$

$$\text{Frame rate} = 12.5 \text{ MHz} / (540) * (646)$$

$$\text{Frame rate} = 35.83 \text{ frame/sec}$$

dss-323

Step 3. Determine LCD, PCD and REGM3

$$T_{\text{CLKIN4DDR}} = T_{\text{TxByteClkHS}} / 16 = T_{\text{VP_PCLK}} / ((\text{REGM3} + 1) * \text{LCD} * \text{PCD})$$

$$((\text{REGM3} + 1) * \text{LCD} * \text{PCD}) = 16 * 3$$

dss-315

If LCD and PCD are set to 1 and 3 respectively, REGM3 is equal to 15.

Step 4. Verify N as integer

Firstly, TL must be determined

$$(HSA_{\text{DISPC}} + HFP_{\text{DISPC}} + PPL + HBP_{\text{DISPC}}) * T_{\text{VP_PCLK}} / T_{\text{TxByteClkHS}} = T_L = 1620$$

dss-316

From **Equation 1**,

$$N * T_{\text{VP_CLK}} = T_L * T_{\text{TxByteClkHS}}$$

$$N = T_{\text{TxByteClkHS}} * T_L / T_{\text{VP_CLK}} = T_L / (R * \text{PCD})$$

$$N = 14580$$

N is an integer.

Step 5. Determine HFP and HBP of the DSI protocol engine

From **Equation 3**,

$$(HSA_{\text{DISPC}} + HFP_{\text{DISPC}} + PPL + HBP_{\text{DISPC}}) * T_{\text{VP_PCLK}} / T_{\text{TxByteClkHS}} - (4/\text{NDL} + (\text{WC} + 6)/\text{NDL}) = HFP_{\text{DSI}} + HBP_{\text{DSI}}$$

$$HFP_{\text{DSI}} + HBP_{\text{DSI}} = 170$$

dss-317

From **Equation 4**,

$$HFP_{\text{DSI}} = ((HFP_{\text{DISPC}} * \text{bits_per_pixel}) / \text{NDL} * 8) - (2 / \text{NDL})$$

$$HFP_{\text{DSI}} = 58$$

$$HBP_{\text{DSI}} = 170 - 58 = 112$$

dss-321

7.6.4 DSI Video Mode Using the DISPC Video Port

This section details the basic programming model of video mode using the DISPC video port.

The DSI interface is connected to an external MIPI display controller and the following parameters are used:

- 1 data lane: NDL = 1
- Clock lane at 150 MHz (DSI_DDR_CLK)
- LCD size is 640 x 480:
 - 480 pixels per line (PPL)
 - 680 lines per panel (LPP)
- Display controller input format: YUV
- Display controller output format: RGB888, that is 24 bits per pixel (BPP)
- Word Count: WC = 3 x PPL
- DSS2_ALWON_FLCK=26 MHz is used as a reference clock for DSI PLL
- Virtual channel 0 (VC0) is used for video mode.
- Interleaving is not used.
- It is assumed that all modules used in these programming models are in after-POR state.

[Figure 7-154](#) is an overview of the connections in the display subsystem.

Figure 7-154. Overview

dss-330

The steps listed in [Table 7-86](#) are described in the following sections.

Table 7-86. Main Steps

Steps	Section
Configure DSS clocks	Section 7.6.4.1, Display Subsystem Clock Configuration
Configure the DSI and DSI PLL	Section 7.6.4.2, Configure DSI, DSI PLL and Complex I/O
Configure the external MIPI display controller	Section 7.6.4.3, Initialization of the External MIPI Display Controller
Configure the DISPC	Section 7.6.4.4, Configure the DISPC
Enable video mode using the DISPC video port	Section 7.6.4.5, Enable Video Mode Using the DISPC Video Port

The programming model must be followed in the order of the following sections.

7.6.4.1 Display Subsystem Clock Configuration

[Table 7-87](#) lists the steps required to enable the clocks.

Table 7-87. PRCM Registers

Steps	Registers	Value
Set the divided DPLL value for DSS1.	CM_CLKSEL_DSS[4:0] CLKSEL_DSS1	0x9
Disable autoidle mode.	CM_AUTOIDLE_DSS[31:0]	0x0
Domain sleep is disabled.	CM_SLEEPDEP_DSS[31:0]	0x0
Automatic transition between active and inactive are disabled.	CM_CLKSTCTRL_DSS[31:0]	0x0
Enable DSS1, DSS2 and TV clock (DSS1_ALWON_FCLK, DSS2_ALWON_FCLK and TV_CLK). TV_CLK is only need for correct Reset.	CM_FCLKEN_DSS[31:0]	0x7
Enable the subsystem interface clock (DSS_L3_ICLK and DSS_L4_ICLK).	CM_ICLKEN_DSS[31:0]	0x1

7.6.4.2 Configure DSI, DSI PLL and Complex I/O

7.6.4.2.1 Reset DSI Modules

Table 7-88 lists the steps required to reset the DSI modules.

Table 7-88. Resets

Steps	Registers	Value
Reset IRQ status.	DSI_IRQSTATUS[31:0]	0x0
OCP and functional clock are maintained during wakeup, smart idle, and reset DSI.	DSI_SYSCONFIG[31:0]	0x312
Wait until RESET_DONE ≠ 0.	DSI_SYSSTATUS[0] RESET_DONE	Read 0x1

7.6.4.2.2 Set Up DSI DPLL

Table 7-89 lists the steps required to configure DSI PLL.

Table 7-89. DSI PLL Configuration Registers

Steps	Registers	Value
Turn on PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CTRL	0x2
Wait until PLL_PWR_STATUS = 0x2.	DSI_CLK_CTRL[29:28] PLL_PWR_STATUS	Read 0x2
See the calculation following this table.	DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLK_DIV	5
See the calculation following this table.	DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV	15
See the calculation following this table.	DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM	150
See calculation following this table.	DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN	12
Enable PLLStopMode.	DSI_PLL_CONFIGURATION1[0]	0x1
The DSI protocol engine clock divider, DSS clock divider, CLKIN4DDR, and PLL reference clock are enabled. PLL internal reference frequency is between 0.032 MHz and 52 MHz.	DSI_PLL_CONFIGURATION2[31:0]	0x5600E
Manual mode	DSI_PLL_CONTROL[31:0]	0x0
Request PLL locking sequence.	DSI_PLL_GO[0] DSI_PLL_GO	0x1
Read until DSI_PLL_GO = 0	DSI_PLL_GO[0] DSI_PLL_GO	Read 0x0
PLL is locked.	DSI_PLL_STATUS[1] DSI_PLL_LOCK	Read 0x1
Turn on PLL and HSDIVIDER; the DSI functional clock 30-MHz sync is rising/rising; the DSIStopClk signal is automatically asserted/deasserted; the L3_ICLK clock to the DSI complex I/O is not gated; and LPCLKDIVISOR = 8	DSI_CLK_CTRL[31:0]	0x8024 4008

- Calculate the divider value for the DSI protocol engine clock source:

$$\text{RegM4} = \text{FCLKIN4DDR}/\text{DSI2_PLL_FCLK} - 1$$

$$\text{FCLKIN4DDR} = 4 \times \text{FCLKIN}$$

$$\text{RegM4} = 5$$

- Determine LCD, PCD, and REGM3:

Calculate the divider value for DSS clock source: Same as Step 3.

$$\text{RegM3} = ((\text{BPP} \times 2)/(\text{DISPC_LCD} \times \text{DISPC_PCD} \times \text{NDL})) - 1$$

$$\text{RegM3} = 15$$

dss-E127

- Calculate N Divider for PLL:

$$\text{FCLKIN4DDR} = \text{FCLKIN} \times 4$$

$$\text{RegN} = (\text{FDSI_PLL_REFCLK}/\text{FINT}) - 1$$

$$\text{FDSI_PLL_REFCLK} = 26 \text{ MHz (system clock)}$$

$$\text{Fint} = 2 \text{ MHz (reduce PLL lock time)}$$

$$\text{RegN} = 12$$

dss-E128

- Calculate M divider for PLL:

$$\text{RegM} = ((\text{RegN} + 1) \times (\text{FCLKIN4DDR} / (2 \times \text{FDSI_PLL_REFCLK})))$$

$$\text{FCLKIN4DDR} = 4 \times 150 \text{ MHz}$$

$$\text{RegM} = 150$$

dss-E129

7.6.4.2.3 Switch to DSI PLL Clock Source

Select the DSI_PLL1 clock as the DISPC functional clock, and select the DSI_PLL2 clock as the DSI functional clock: Set [DSS_CONTROL](#) to 0x3.

7.6.4.2.4 Set Up DSI Protocol Engine

7.6.4.2.4.1 Set Up DSI Control Registers

[Table 7-90](#) lists the steps to set up the DSI control registers. [Table 7-91](#) lists the steps to set up the DSI complex I/O registers.

Table 7-90. DSI Control Registers

Steps	Registers	Value
Enable SYNCLOST event.	DSI IRQENABLE[31:0]	0x4 0000
Set PACKET_SENT_IRQ_EN.	DSI_VCO_IRQENABLE[31:0]	0x4
While the HSYNC START pulse is detected, the associated short packet HSYNC START is generated.	DSI_CTRL[17] VP_HSYNC_START	0x1
While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated.	DSI_CTRL[15] VP_VSYNC_START	0x1
Set the trigger reset mode to <i>immediate</i> .	DSI_CTRL[14] TRIGGER_RESET_MODE	0x1
Activate two line buffers.	DSI_CTRL[13:12] LINE_BUFFER	0x2
HSYNC signal on the video port is active high.	DSI_CTRL[10] VP_HSYNC_POL	0x1
VSYNC on the video port is active high.	DSI_CTRL[11] VP_VSYNC_POL	0x1
Set the Data Enable signal on the video port as active high.	DSI_CTRL[9] VP_DE_POL	0x1
Set the size of the video port data bus for the RGB format: 0x2 for RGB 888.	DSI_CTRL[7:6] VP_DATA_BUS_WIDTH	0x2
VP_CLK_RATIO is not used if video port is used to provide data in video mode	DSI_CTRL[4] VP_CLK_RATIO	0x0

Table 7-90. DSI Control Registers (continued)

Steps	Registers	Value
Set the arbitration scheme for granting the VC pending ready requests in the TX FIFO as Sequential Scheme.	DSI_CTRL[3] TX_FIFO_ARBITRATION	0x1
Enable the ECC check for the received header.	DSI_CTRL[2] ECC_RX_EN	0x1

Table 7-91. DSI Complex I/O Registers

Steps	Registers	Value
GOBIT, complex I/O power ON, select data, and clock position	DSI_COMPLEXIO_CFG1	0x4800 0032
Clear Reg	DSI_COMPLEXIO_IRQSTATUS	0xC3F39CE7
Disable IRQ	DSI_COMPLEXIO_IRQENABLE	0x0
Enable I/F	DSI_CTRL[0] IF_EN	0x1
Disable I/F	DSI_CTRL[0] IF_EN	0x0
Wait until IF_EN = 0	DSI_CTRL[0] IF_EN	Read 0x0
Enable Low Power clock	DSI_CLK_CTRL[20] LP_CLK_ENABLE	0x1
Reset is done.	DSI_COMPLEXIO_CFG1[29] RESET_DONE	Read 0x1
Power control is on.	DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS	Read 0x1
Reset is complete.	DSI_SYSSTATUS[0] RESETDONE	Read 0x1

7.6.4.2.4.2 Configure DSI Timing and Virtual Channels

Table 7-92 lists the steps to configure DSI timing and the virtual channels.

Table 7-92. DSI Timing Registers

Steps	Registers	Value
STOP_STATE_COUNTER_IO = 0x999	DSI_TIMING1[31:0]	0x0000 0999
HS_TX_TO_X8, HS_TX_TO_COUNTER = 0x0FD2, LP_RX_TO_X16, LP_RX_TO_COUNTER = 0x00CD	DSI_TIMING2[31:0]	0x2FD2 40CD
(HSA24) (HFP12) HBP	DSI_VM_TIMING1[31:0]	0x0000 700A
(WINDOW_SYNC24) (VSA16) (DSI_VFP8) VBP	DSI_VM_TIMING2[31:0]	0x0401 0101
(TL16) DSI_VACT	DSI_VM_TIMING3[31:0]	0x05BB 0280
(ENTER_HS_MODE_LATENCY16) EXIT_HS_MODE_LATENCY	DSI_VM_TIMING7[31:0]	0x0000 C000A
DDR_CLK_PRE8 DDR_CLK_POST	DSI_CLK_TIMING[31:0]	0x0000 0F0B
HS speed, ECC generation for the Transmit, Enable CheckSum generation for the Payload.	DSI_VC0_CTRL[31:0]	0x2080 0390

- Freq TxByteClkHS:

$$\text{FHSB} = \text{FCLKIN4DDR}/16$$

$$\text{FVPP} = \text{FCLKIN4DDR}/((\text{RegM3} + 1) \times \text{DISPC_LCD} * \text{DISPC_PCD})$$

$$\text{FVP} = \text{FCLKIN4DDR}/(\text{RegM3} + 1) \quad (28)$$

- Length of the line in video mode in Nb of byte clock cycles (TxByteClkHS):

$$TL = FHSB/FVPP \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)$$

$$TL1f = (BPP/(8 \times NDL)) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP) \quad (29)$$

- Blanking periods (HBP + HFP) in DSI are calculated based on the following formula:

$$(DISPC_HSA + DISPC_HBP + PPL + DISPC_HFP) \times Fppi = (HS + HBP + ((WC + 6)/NDL) + HFP) \times Fvp$$

$$HBP + HFP = (TVPP/THSB) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP - (HS + (WC + 6)/NDL))$$

$$HBPplusHFP = (FHSB/FVPP) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP) - (HS + WC + 6)/NDL)$$

$$HBPplusHFPf = ((FHSB/FVPP) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)) - ((HS + WC + 6)/NDL)$$

$$HFP = (DISPC_HFP \times BPP)/(NDL \times 8) - (2/NDL)$$

$$HBP = HBPplusHFP - HFP \quad (30)$$

7.6.4.2.5 Configure DSI_PHY

Calculate the timing in the functions of DDR_CLK_P (see [Table 7-93](#)). In the example, DDR_CLK_P = 1000/DSI_DDR_CLK. See [Section 7.4.3.2, Clock Requirements](#), for details on timing calculation.

Table 7-93. Calculate DSI_PHY Timing

Steps	Registers	Value
Refer to Section 7.4.3.2	DSI_PHY_REGISTER0[31:24] REG_THSPREPARE	CEIL(70 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0[23:16] REG_THSPRPR_THSZERO	ceil(175 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0[7:0] REG_THSEXIT	ceil(145 ns/DDR clock period)
	DSI_PHY_REGISTER0[15:8] REG_THSTRAIL	ceil(60 ns/DDR clock period) + 5
	DSI_PHY_REGISTER2[7:0] REG_TCLKPREPARE	ceil(65 ns/DDR clock period)
	DSI_PHY_REGISTER1[7:0] REG_TCLKZERO	ceil(265 ns/DDR clock period)
	DSI_PHY_REGISTER1[15:8] REG_TCLKTRAIL	ceil(60 ns/DDR clock period) + 2
	DSI_PHY_REGISTER1[20:16] REG_TLPXBY2	ceil(25ns/DDR clock period)

NOTE: Keep Reserved bits at reset value in the [DSI_PHY_REGISTER1](#) and [DSI_PHY_REGISTER2](#) registers.

7.6.4.2.6 Drive Stop State

[Table 7-94](#) lists the steps to Drive Stop State.

Table 7-94. Drive Stop State

Steps	Registers	Value
Force TX stop mode	DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO	0x1
Wait until FORCE_TX_STOP_MODE_IO = 0	DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO	Read 0x0

7.6.4.3 Initialization of the External MIPI Display Controller

1. Wait for the external MIPI display controller initialization after power up.
In this example, the external MIPI display controller is reset using GPIO 87.
2. Configure the external MIPI display controller.

7.6.4.4 Configure the DISPC

7.6.4.4.1 Reset DISPC

[Table 7-95](#) lists the step sequence to reset the DISPC.

Table 7-95. Reset DISPC

Steps	Registers	Value
Reset the DISPC.	DISPC_SYSCONFIG[1] SOFTRESET	0x1
DISPC is reset.	DISPC_SYSCONFIG[0] RESETDONE	Read 0x1
No standby: MStandby is never asserted.	DISPC_SYSCONFIG [13:12] MIDLEMODE	0x1
Disable idle mode.	DISPC_SYSCONFIG [4:3] SIDLEMODE	0x1
Disable all interrupts.	DISPC_IRQENABLE[31:0]	0x0

7.6.4.4.2 Configure DISPC Timing, Window, and Color

[Table 7-96](#) lists the steps to configure the DISPC registers. [Table 7-97](#) lists the steps to configure the color space coefficient registers.

[Table 7-98](#) lists the steps to configure [DISPC_CONTROL](#).

Table 7-96. Configure DISPC Registers

Steps	Registers	Value
Set horizontal timings.	DISPC_TIMING_H	(HBP – 120) (HFP – 18) HSA – 1
Set vertical timing.	DISPC_TIMING_V	(HBP – 120) (HFP – 18) HSA – 1
Set LCD – PCD display controller and pixel clock divisor.	DISPC_DIVISOR	LDC = %1 PXLCLK = %4
Set the size of the LCD – 1.	DISPC_SIZE_LCD	(LPP – 1 + DS1_VFP)16 (PPL – 1)
Set default RGB value when there is no data.	DISPC_DEFAULT_COLOR0	0xFF
Set video FIFO height and low threshold.	DISPC_VID1_FIFO_THRESHOLD	0xfc00c0
Set the X Y location of the upper left pixel (0 = 0) to the upper left corner.	DISPC_VID1_POSITION	0x0
Set size of the window.	DISPC_VID1_SIZE	(LPP – 1) 16 (PPL – 1)
Set the size of the picture.	DISPC_VID1_PICTURE_SIZE	(LPP – 1) 16 (PPL – 1)
Set the input address picture.	DISPC_VID1_BA0	0x–

Table 7-97. Configure Color Space Coefficient Registers

Comments	Registers	Value

The input image is converted from UYVY into RGB (see [Table 7-99](#)) :

Table 7-99. Configure DISPC_VID1_ATTRIBUTES

Comments	Registers	Value
Row of VIDn will not be read twice.	DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
8 x 32-bit bursts	DISPC_VID1_ATTRIBUTES[15:14] VIDBURSTSIZE	0x1
Full range selected: Y is not modified before the color space conversion.	DISPC_VID1_ATTRIBUTES[11] VIDFULLRANGE	0x1
Enable color space conversion CbYCr to RGB.	DISPC_VID1_ATTRIBUTES[9] VIDCOLORCONVENABLE	0x1
UYVY	DISPC_VID1_ATTRIBUTES[4:1] VIDFORMAT	0xB
Video disabled	DISPC_VID1_ATTRIBUTES[0] VIDENABLE	0x0

7.6.4.5 Enable Video Mode Using the DISPC Video Port

[Table 7-100](#) lists the steps to enable DISPC to send frames continuously.

Table 7-100. Enable DISPC

Steps	Registers	Value
Set up long packet header	DSI_VC0_LONG_PACKET_HEADER[31:0]	0x0005 A03E
Enable VC0.	DSI_VC0_CTRL[1] VC_EN	0x1
Enable IF.	DSI_CTRL[0] IF_EN	0x1
Wait until IF_EN ≠ 0.	DSI_CTRL[0] IF_EN	Read 0x0
Enable VID1.	DISPC_VID1_ATTRIBUTES[0] VIDENABLE	0x1
Enable LCD interface.	DISPC_CONTROL[0] LCDENABLE	0x1
Enable GOLCD.	DISPC_CONTROL[5] GOLCD	0x1
Wait until GOLCD = 0.	DISPC_CONTROL[5] GOLCD	Read 0x0

7.6.5 DSI Command Mode Using the DISPC Video Port

This section presents some generic use cases and tips for setting the modules of the display subsystem.

7.6.5.1 Display Subsystem Use Cases and Tips

This section explains the basic programming model of command mode using the DISPC video port.

The DSI interface is connected to an external MIPI DISPC using the following parameters:

- One data lane: NDL = 1
- Clock lane at 150 MHz (DSI_DDR_CLK)
- LCD size is 640 x 480:

- 480 PPL
- 680 LPP
- DISPC input format: YUV
- DISPC output format: RGB888 (24 BPP)
- Word Count: WC = 3 x PPL
- DSS2_ALWON_FLCK = 26 MHz used as a reference clock for DSI PLL
- Virtual channel 1 (VC1) used for command mode to configure the eternal DISPC, and virtual channel 0 (VC0) used to send data
- Automatic TE used for synchronization
- Interleaving not used
- It is assumed that all modules used in these programming models are in after-POR state.

Figure 7-155 is an overview of the connections in the display subsystem.

Figure 7-155. Overview

dss-330

Table 7-101 lists the steps of the main sequence and the sections that describe them.

Table 7-101. Main Sequence

Steps	Register/Bit Field/Programming Model
Configure DSS clocks.	Section 7.6.5.1.1, Configure DSS Clocks at the PRCM Module
Configure the DSI protocol engine and DSI PLL.	Section 7.6.5.1.2, Configure DSI Protocol Engine, DSI PLL, and Complex I/O
Configure the external MIPI display controller.	Section 7.6.5.1.3, Initialization of the External MIPI Display Controller
Configure the DISPC.	Section 7.6.5.1.4, Configure the DISPC
Enable command mode using the DISPC video port.	Section 7.6.5.1.5, Enable Command Mode Using the DISPC Video Port
Send a frame data to LCD panel using automatic TE.	Section 7.6.5.1.6, Send Frame Data to LCD Panel Using Automatic TE

The programming model must follow the step sequence.

7.6.5.1.1 Configure DSS Clocks at the PRCM Module

Table 7-102 lists the steps required to enable the clocks.

Table 7-102. Configure DSS Clocks at the PRCM Module

Steps	Register/Bit Field/Programming Model	Value
Set the divided DPLL value for DSS1.	CM_CLKSEL_DSS[4:0] CLKSEL_DSS1	0x9
Disable autoidle mode.	CM_AUTOIDLE_DSS[0] AUTO_DSS	0x0
Domain sleep is disabled.	CM_SLEEPDEP_DSS[2:0] EN_IVA2, EN_MPU, EN_CORE	0x0
Disable automatic transition.	CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS	0x0
Enable the DSS1_ALWON_FCLK, DSS2_ALWON_FCLK, and TV_CLK functional clocks. ⁽¹⁾	CM_FCLKEN_DSS[2:0] EN_TV, EN_DSS2, EN_DSS1	0x7
Enable the DSS_L3_ICLK and DSS_L4_ICLK interface clocks.	CM_ICLKEN_DSS[0] EN_DSS	0x1

⁽¹⁾ TV_CLK is required only for a correct reset.

7.6.5.1.2 Configure DSI Protocol Engine, DSI PLL, and Complex I/O

Table 7-103 lists the steps to configure the DSI protocol engine, DSI PLL, and complex I/O and the sections that describe the sequence.

Table 7-103. Configure DSI Protocol Engine, DSI PLL, and Complex I/O

Steps	Register/Bit Field/Programming Model
Reset DSI modules.	Section 7.6.5.1.2.1, Reset DSI Modules
Configure DSI DPLL.	Section 7.6.5.1.2.2, Configure DSI PLL
Switch to DSI PLL clock source.	Section 7.6.5.1.2.3, Switch to DSI PLL Clock Source
Configure DSI protocol engine.	Section 7.6.5.1.2.4, Configure DSI Protocol Engine
Configure DSI_PHY.	Section 7.6.5.1.2.5, Configure DSI_PHY
Drive stop state.	Section 7.6.5.1.2.6, Drive Stop State

7.6.5.1.2.1 Reset DSI Modules

Table 7-104 lists the steps required to reset the DSI modules.

Table 7-104. Reset DSI Modules

Steps	Register/Bit Field/Programming	Value
Clear DSI IRQ status.	DSI_IRQSTATUS[31:0]	0x0
Maintain interface and functional clock during wakeup.	DSI_SYSCONFIG[9:8] CLOCKACTIVITY	0x3
Enable smart-idle for power management.	DSI_SYSCONFIG[4:3] SIDLEMODE	0x2
Set DSI reset.	DSI_SYSCONFIG[1] SOFT_RESET	0x1
Wait until RESET_DONE = 1.	DSI_SYSSTATUS[0] RESET_DONE	

7.6.5.1.2.2 Configure DSI PLL

Table 7-105 lists the steps required to configure the DSI PLL.

Table 7-105. Configure DSI PLL

Steps	Register/Bit Field/Programming	Value
Enable PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	0x2
Wait until PLL_PWR_STATUS = 0x2.	DSI_CLK_CTRL[29:28] PLL_PWR_STATUS	
Set the REGM4 value (see (1)).	DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLK_DIV	5
Set the REGM3 value (see (2)).	DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV	15
Set the REGN value (see (3)).	DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN	12
Set the REGM value (see (4)).	DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM	150
Enable PLL STOPMODE.	DSI_PLL_CONFIGURATION1[0] DSI_PLL_STOPMODE	0x1
Enable PLL reference clock control.	DSI_PLL_CONFIGURATION2[13] DSI_PLL_REFEN	0x1
Enable CLKIN4DDR control.	DSI_PLL_CONFIGURATION2[14] DSI_PHY_CLKINEN	0x1
Enable DSS clock divider.	DSI_PLL_CONFIGURATION2[16] DSS_CLOCK_EN	0x1
Enable DSI protocol engine clock divider.	DSI_PLL_CONFIGURATION2[18] DSI_PROTO_CLOCK_EN	0x1
Enable DSI configuration update with DISPC_UPDATE_SYNC.	DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE	0x0
Start PLL locking sequence.	DSI_PLL_GO[0] DSI_PLL_GO	0x1
Wait until DSI_PLL_GO = 0.	DSI_PLL_GO[0] DSI_PLL_GO	
Check whether PLL is locked.	DSI_PLL_STATUS[1] DSI_PLL_LOCK	0x1
Set the LP mode clock ratio.	DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR	0x8
Set L3_ICLK clock to the DSI complex I/O to not gated.	DSI_CLK_CTRL[14] CIO_CLK_ICG	0x1
Enable the automatic assertion/deassertion of the DSISStopClk signal.	DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE	0x1
Specify that the DSI functional clock is higher than 30 MHz with a synchronization rising/rising.	DSI_CLK_CTRL[21] LP_RX_SYNCHRO_ENABLE	0x1
Turn on PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	0x2

(1) Calculate the divider value for the DSI protocol engine clock source:

$$\text{RegM4} = \text{FCLKIN4DDR/FDSI_PLL_REFCLK} - 1$$

$$\text{FCLKIN4DDR} = 4 \times \text{FCLKIN}$$

$$\text{RegM4} = 5$$

dss-E126

(2) Determine LCD, PCD, and REGM3:

Calculate the divider value for the DSS clock source: Same as Step 3.

$$\text{RegM3} = ((\text{BPP} \times 2) / (\text{DISPC_LCD} \times \text{DISPC_PCD} \times \text{NDL})) - 1$$

$$\text{RegM3} = 15$$

dss-E127

(3) Calculate N divider for PLL:

$FCLKIN4DDR = FCLKIN \times 4$
 $RegN = (FDSI_PLL_REFCLK/F INT) - 1$
 $FDSI_PLL_REFCLK = 26 \text{ MHz} \text{ (system clock)}$
 $Fint = 2 \text{ MHz} \text{ (reduce PLL lock time)}$
 $RegN = 12$

dss-E128

(4) Calculate M divider for PLL:

$RegM = ((RegN + 1) \times (FCLKIN4DDR / (2 \times FDSI_PLL_REFCLK)))$
 $FCLKIN4DDR = 4 \times 150 \text{ MHz}$
 $RegM = 150$

dss-E129

7.6.5.1.2.3 Switch to DSI PLL Clock Source

Table 7-106 lists the sequence to switch the DSI and DISPC module clocks to DSI PLL clock source.

Table 7-106. Switch to DSI PLL Clock Source

Steps	Register/Bit Field/Programming	Value
Switch DISPC clock to DSI1_PLL_FCLK.	DSS_CONTROL[0] DISPC_CLK_SWITCH	0x1
Switch DSI clock to DSI2_PLL_FCLK.	DSS_CONTROL[1] DSI_CLK_SWITCH	0x1

7.6.5.1.2.4 Configure DSI Protocol Engine

7.6.5.1.2.4.1 Set Up DSI Control Registers

Table 7-107 lists the steps required to set up the DSI control registers. Table 7-108 lists the steps to set up the DSI complex I/O registers.

Table 7-107. DSI Control Registers

Steps	Register/Bit Field/Programming	Value
Enable SYNCLOST event.	DSI_IRQENABLE[18] SYNC_LOST_IRQ_EN	0x1
Enable IRQ to indicate that packet has been sent on VC1.	DSI_VC1_IRQENABLE[2] PACKET_SENT_IRQ	0x1
Enable IRQ to indicate that packet has been sent on VC0.	DSI_VC0_IRQENABLE[2] PACKET_SENT_IRQ	0x1
Set the trigger reset mode to <i>immediate</i> .	DSI_CTRL[14] TRIGGER_RESET_MODE	0x1
Activate the two line buffers.	DSI_CTRL[13:12] LINE_BUFFER	0x2
Set the size of the video port data bus to 24 bits (RGB 888).	DSI_CTRL[7:6] VP_DATA_BUS_WIDTH	0x2
Define the ratio between VP_CLK and VP_PCLK.	DSI_CTRL[4] VP_CLK_RATIO	0x1
Set the arbitration scheme for granting the VC pending ready requests in the TX FIFO as sequential scheme.	DSI_CTRL[3] TX_FIFO_ARBITRATION	0x1
Enable the ECC check for the received header.	DSI_CTRL[2] ECC_RX_EN	0x1

Table 7-108. DSI Complex I/O Registers

Steps	Register/Bit Field/Programming	Value
Determine the position of the clock lane.	DSI_COMPLEXIO_CFG1[2:0] CLOCK_POSITION	0x2
Determine the position of data 1 lane.	DSI_COMPLEXIO_CFG1[6:4] DATA1_POSITION	0x3
Turn on COMPLEXIO.	DSI_COMPLEXIO_CFG1[28:27] PWR_CMD	0x1

Table 7-108. DSI Complex I/O Registers (continued)

Steps	Register/Bit Field/Programming	Value
Enable the synchronization of the shadow registers with DISPC_UPDATE_SYNC.	DSI_COMPLEXIO_CFG1[30] GOBIT	0x1
Clear all COMPLEXIO IRQ status.	DSI_COMPLEXIO_IRQSTATUS	0xC3F39CE7
Disable all COMPLEXIO IRQs.	DSI_COMPLEXIO_IRQENABLE	0x0
Enable interface.	DSI_CTRL[0] IF_EN	0x1
Disable interface.	DSI_CTRL[0] IF_EN	0x0
Wait until IF_EN = 0.	DSI_CTRL[0] IF_EN	
Enable the LP clock.	DSI_CLK_CTRL[20] LP_CLK_ENABLE	0x1
Check whether reset is complete.	DSI_COMPLEXIO_CFG1[29] RESET_DONE	0x1
Check whether power control is on.	DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS	0x1
Check whether reset is complete.	DSI_SYSSTATUS[0] RESETDONE	0x1

7.6.5.1.2.4.2 Configure DSI Timing and Virtual Channels

Table 7-109 lists the steps to configure DSI timing and the virtual channels.

Table 7-109. DSI Timing Registers

Steps	Register/Bit Field/Programming	Value
Determine the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[12:0] STOP_STATE_COUNTER_IO	0x999
Disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[13] STOP_STATE_X4_IO	0x0
Disable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[14] STOP_STATE_X16_IO	0x0
Clear turn-around timer settings.	DSI_TIMING1[30:16]	0x0000
Determine the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[12:0] LP_RX_TO_COUNTER	0x0CD
Disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[13] LP_RX_TO_X4	0x0
Enable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[14] LP_RX_TO_X16	0x1
Determine the number of TxByteClkHS clock cycles for the HS RX timer.	DSI_TIMING2[12:0] HS_TX_TO_COUNTER	0xFD2
Disable the multiplication factor of 8 for the number of TxByteClkHS clock cycles for the HS TX timer.	DSI_TIMING2[13] HS_TX_TO_X8	0x0
Enable the multiplication factor of 16 for the number of TxByteClkHS clock cycles for the HS TX timer.	DSI_TIMING2[14] HS_TX_TO_X16	0x1
DDR_CLK_PRE8 DDR_CLK_POST	DSI_CLK_TIMING[31:0]	0x0000 0F0B
Configuration of VC1		
Enable the checksum generation for the transmit payload.	DSI_VC1_CTRL[7] CS_TX_EN	0x1
Enable the ECC generation for the transmit header.	DSI_VC1_CTRL[8] ECC_TX_EN	0x1
Disable DMA request for TX FIFO.	DSI_VC1_CTRL[23:21] DMA_TX_REQ_NB	0x4
Disable DMA request for RX FIFO.	DSI_VC1_CTRL[29:27] DMA_RX_REQ_NB	0x4
Configuration of VC0		
Selects source of data and enable VP_STALL.	DSI_VC0_CTRL[1] SOURCE	0x1

Table 7-109. DSI Timing Registers (continued)

Steps	Register/Bit Field/Programming	Value
Enable the checksum generation for the transmit payload.	DSI_VC0_CTRL[7] CS_TX_EN	0x1
Enable the ECC generation for the transmit header.	DSI_VC0_CTRL[8] ECC_TX_EN	0x1
Enable high-speed mode to send short and long packets to the peripheral.	DSI_VC0_CTRL[9] MODE_SPEED	0x1
Disable DMA request for TX FIFO.	DSI_VC0_CTRL[23:21] DMA_TX_REQ_NB	0x4
Disable DMA request for RX FIFO.	DSI_VC0_CTRL[29:27] DMA_RX_REQ_NB	0x4
Configuration TX and RX FIFO		
Set size of the RX FIFO allocated for VC1 to 32 x 33 bits.	DSI_RX_FIFO_VC_SIZE[15:12] VC1_FIFO_SIZE	0x1
Set size of the TX and RX FIFO allocated for VC1 to 96 x 33 bits.	DSI_TX_FIFO_VC_SIZE[15:12] VC1_FIFO_SIZE	0x3

- Freq TxByteClkHS:

$$\text{FHSB} = \text{FCLKIN4DDR}/16$$

$$\text{FVPP} = \text{FCLKIN4DDR}/((\text{RegM3} + 1) \times \text{DISPC_LCD} * \text{DISPC_PCD})$$

$$\text{FVP} = \text{FCLKIN4DDR}/(\text{RegM3} + 1)$$

dss-E130

- Length of the line in video mode in number of byte clock cycles (TxByteClkHS):

$$\text{TL} = \text{FHSB}/\text{FVPP} \times (\text{DISPC_HSA} + \text{DISPC_HFP} + \text{PPL} + \text{DISPC_HBP})$$

$$\text{TL1f} = (\text{BPP}/(8 \times \text{NDL})) \times (\text{DISPC_HSA} + \text{DISPC_HFP} + \text{PPL} + \text{DISPC_HBP})$$

dss-E131

- Blanking periods (HBP + HFP) in DSI are calculated based on the following formula:

$$(\text{DISPC_HSA} + \text{DISPC_HBP} + \text{PPL} + \text{DISPC_HFP}) \times \text{Fppi} = (\text{HS} + \text{HBP} + ((\text{WC} + 6)/\text{NDL}) + \text{HFP}) \times \text{Fvp}$$

$$\text{HBP} + \text{HFP} = (\text{TVPP}/\text{THSB}) \times (\text{DISPC_HSA} + \text{DISPC_HFP} + \text{PPL} + \text{DISPC_HBP}) - (\text{HS} + (\text{WC} + 6)/\text{NDL})$$

$$\text{HBPplusHFP} = (\text{FHSB}/\text{FVPP}) \times (\text{DISPC_HSA} + \text{DISPC_HFP} + \text{PPL} + \text{DISPC_HBP}) - (\text{HS} + \text{WC} + 6)/\text{NDL}$$

$$\text{HBPplusHFPf} = ((\text{FHSB}/\text{FVPP}) \times (\text{DISPC_HSA} + \text{DISPC_HFP} + \text{PPL} + \text{DISPC_HBP})) - ((\text{HS} + \text{WC} + 6)/\text{NDL})$$

$$\text{HFP} = (\text{DISPC_HFP} \times \text{BPP})/(\text{NDL} \times 8) - (2/\text{NDL})$$

$$\text{HBP} = \text{HBPplusHFP} - \text{HFP}$$

dss-E132

7.6.5.1.2.5 Configure DSI_PHY Timing

Table 7-110 summarizes DSI_PHY timing in the functions of DDR_CLK_P with DDR_CLK_P = 1000/DSI_DDR_CLK. For more details on timing calculation, see [Section 7.4.3.2, Clock Requirements](#).

Table 7-110. Configure DSI_PHY Timing

Steps	Register/Bit Field/Programming	Value
Settings of the DSI protocol timing. For a complete description of timing specifications, see Section 7.4.3.2, Clock Requirements .	DSI_PHY_REGISTER0[31:24] REG_THSPREPARE	CEIL(70 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0[23:16] REG_THSPRPR_THSZERO	ceil(175 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0[7:0] REG_THSEXIT	ceil(145 ns/DDR clock period)

Table 7-110. Configure DSI_PHY Timing (continued)

Steps	Register/Bit Field/Programming	Value
	DSI_PHY_REGISTER0[15:8] REG_THSTRAIL	ceil(60 ns/DDR clock period) + 5
	DSI_PHY_REGISTER2[7:0] REG_TCLKPREPARE	ceil(65 ns/DDR clock period)
	DSI_PHY_REGISTER1[7:0] REG_TCLKZERO	ceil(265 ns/DDR clock period)
	DSI_PHY_REGISTER1[15:8] REG_TCLKTRAIL	ceil(60 ns/DDR clock period) + 2
	DSI_PHY_REGISTER1[20:16] REG_TLPXBY2	ceil(25ns/DDR clock period)

NOTE: Keep Reserved bits at reset value in the [DSI_PHY_REGISTER1](#) and [DSI_PHY_REGISTER2](#) registers.

7.6.5.1.2.6 Drive Stop State

[Table 7-111](#) lists the steps to drive the stop state.

Table 7-111. Drive Stop State

Steps	Register/Bit Field/Programming	Value
Force TX stop mode.	DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO	0x1
Wait until FORCE_TX_STOP_MODE_IO = 0.	DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO	

7.6.5.1.3 Initialization of the External MIPI LCD Controller

[Table 7-112](#) lists the steps to initialize the external MIPI LCD controller.

Table 7-112. Initialization of the External MIPI LCD Controller

Steps	Register/Bit Field/Programming	Value
Reset the MIPI LCD controller using GPIO87.	–	0x1
Wait until initialization of the external MIPI LCD controller is finished after power up.	–	–
Configure the external MIPI LCD controller.	–	–

7.6.5.1.4 Configure the DISPC

7.6.5.1.4.1 Reset DISPC

[Table 7-113](#) lists the steps to reset the DISPC.

Table 7-113. Reset DISPC

Steps	Register/Bit Field/Programming	Value
Reset the DISPC.	DISPC_SYSCONFIG[1] SOFTRESET	0x1
Wait until RESETDONE = 1.	DISPC_SYSCONFIG[0] RESETDONE	
Disable master interface power management.	DISPC_SYSCONFIG [13:12] MIDLEMODE	0x1
Disable slave interface power management.	DISPC_SYSCONFIG [4:3] SIDLEMODE	0x1
Disable all DISPC interrupts.	DISPC_IRQENABLE[31:0]	0x0

7.6.5.1.4.2 Configure DISPC Timing, Window, and Color

[Table 7-114](#) lists the steps to configure the DISPC registers. [Table 7-97](#) lists the steps to configure the color space coefficient registers.

[Table 7-115](#) lists the steps to configure [DISPC_CONTROL](#).

Table 7-114. Configure DISPC Registers

Steps	Register/Bit Field/Programming	Value
Configure LCD output		
Set the logic clock divisor (LCD).	DISPC_DIVISOR[23:16] LCD	0x1
Set the pixel clock divisor (PCD).	DISPC_DIVISOR[7:0] PCD	0x4
Set the number of lines on the LCD panel.	DISPC_SIZE_LCD[26:16] LPP	0x2A7
Set the number of PPL on the LCD panel.	DISPC_SIZE_LCD[10:0] PPL	0x1DF
Set solid background color.	DISPC_DEFAULT_COLOR0	0xFF
Configure VIDEO pipeline VID1.		
Set VID1 FIFO low threshold.	DISPC_VID1_FIFO_THRESHOLD[11:0] VIDFIFOLOWTHRESHOLD	0x0C0
Set VID1 FIFO high threshold.	DISPC_VID1_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD	0xFC0
Set the X position of the VID1 window.	DISPC_VID1_POSITION[10:0] VIDPOSX	0x0
Set the Y position of the VID1 window.	DISPC_VID1_POSITION[26:16] VIDPOSY	0x0
Set the number of lines of the VID1 window.	DISPC_VID1_SIZE[26:16] VIDSIZEY	0x2A7
Set the number of pixels of the VID1 window.	DISPC_VID1_SIZE[10:0] VIDSIZEX	0x1DF
Define the base address of the VID1 frame buffer.	DISPC_VID1_BA0	0x-

Table 7-115. Configure DISPC_CONTROL

Comments	Register/Bit Field/Programming	Value
Enable pixel clock free-running.	DISPC_CONTROL[27] PCLKFREEENABLE	0x1
Disable RFBI.	DISPC_CONTROL[16] GPOUT1	0x1
Disable the stall mode.	DISPC_CONTROL[15] GPOUT0	0x1
Select size of DATALINES.	DISPC_CONTROL[9:8] TFTDATALINES	0x3
Select active matrix display operation mode.	DISPC_CONTROL[3] STNTFT	0x1
Disable LCD output interface.	DISPC_CONTROL[0] LCDENABLE	0x0
Update the internal DISPC registers.	DISPC_CONTROL[5] GOLCD	0x1

7.6.5.1.5 Enable Command Mode Using DISPC Video Port

[Table 7-116](#) lists the steps to enable DISPC to send frames continuously. Two bus turnarounds (BTA) must be generated:

- The first BTA gives bus possession to the display module.
- The second BTA obtains the TE trigger.

Table 7-116. Enable Command Mode and Automatic TE

Steps	Register/Bit Field/Programming	Value
Insert DCS write memory continue code.	DSI_CTRL[25] DCS_CMD_CODE	0x0
Enable automatic insertion of DCS command codes when data is sourced by the video port.	DSI_CTRL[24] DCS_CMD_ENABLE	0x1
Enable VC1.	DSI_VC1_CTRL[0] VC_EN	0x1

Table 7-116. Enable Command Mode and Automatic TE (continued)

Steps	Register/Bit Field/Programming	Value
Enable VC0.	DSI_VC0_CTRL[0] VC_EN	0x1
Enable the interface.	DSI_CTRL[0] IF_EN	0x1
Wait until IF_EN = 1.	DSI_CTRL[0] IF_EN	
Send the sequence to receive the TE trigger from the peripheral. In this use case, code 0x35 + 1 parameter VC = 0, data type = 0x15, DCS write + 1 parameter.	DSI_VC1_SHORT_PACKET_HEADER[31:0] HEADER	0x0000 3515
Wait until PACKET_SENT_IRQ = 1.	DSI_VC1_IRQSTATUS[2] PACKET_SENT_IRQ	
Write 1 to clear PACKET_SENT_IRQ.	DSI_VC1_IRQSTATUS[2] PACKET_SENT_IRQ	0x1

7.6.5.1.6 Send Frame Data to LCD Panel Using Automatic TE

Table 7-117 summarizes the steps to send a frame data to the LCD panel using automatic TE.

Table 7-117. Send Frame Data to LCD Panel Using Automatic TE

Steps	Register/Bit Field/Programming	Value
Enable the transfer between DISPC and DSI. Reset after the transfer is done.	DISPC_CONTROL[0] LCDENABLE	0x1
Specify the number of bytes to send. When DCS insertions is used, word count (WC) must include this one DCS byte.	DSI_VC0_TE[23:0] TE_SIZE	(WC+1)*LPP
Set up long packet header. Send 0x39 DCS long write/write_LUT command packet used to send larger blocks of data to a display module that implements a DCS.	DSI_VC0_LONG_PACKET_HEADER[31:0] HEADER	(WC+1) 8 + 0x39
Enable TE control.	DSI_VC0_TE[30] TE_EN	0x1
Wait until RX FIFO is empty, RX_FIFO_NOT_EMPTY = 0.	DSI_VC1_CTRL[20] RX_FIFO_NOT_EMPTY	0x0
Wait until TX FIFO is not full. TX_FIFO_FULL = 0.	DSI_VC1_CTRL[16] TX_FIFO_FULL	0x0
Enable first BTA to give bus possession to the display module.	DSI_VC1_CTRL[6] BTA_EN	0x1
Wait until BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Write 1 to clear BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Enable second BTA to get the TE trigger.	DSI_VC1_CTRL[6] BTA_EN	0x1
Wait until BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Write 1 to clear BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Wait until transfer is complete.	DSI_VC0_TE[30] TE_EN	Read 0x0

7.7 Display Subsystem Register Manual

CAUTION

- The DISS, DISPC, RFBI, and VENC registers have no register data width access restriction and can be accessed in 8-bit, 16-bit and 32-bit access.
- The DSI complex I/O and DSI PLL control module registers are limited to 32-bit data access; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.
- The DSI protocol engine DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_SHORT_PACKET_HEADER registers are limited to 32-bit data access; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.
- The DSI protocol engine DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is limited to 32-bit and 16-bit data access; 8-bit data accesses are not allowed and can corrupt register content.
- All other DSI protocol engine registers have no register data width access restriction and can be accessed in 8-bit, 16-bit and 32-bit access.

Table 7-118 summarizes the display subsystem instance.

Table 7-118. Display Subsystem Instance Summary

Module Name	Base Address	Size
DSI Protocol Engine	0x4804 FC00	512 bytes
DSI_PHY	0x4804 FE00	64 bytes
DSI PLL Controller	0x4804 FF00	32 bytes
Display Subsystem	0x4805 0000	512 bytes
Display Controller	0x4805 0400	1KB
Display Controller VID1	0x4805 0400	1KB
Display Controller VID2	0x4805 0400	1KB
RFBI	0x4805 0800	256 bytes
Video Encoder	0x4805 0C00	256 bytes

7.7.1 Display Subsystem Register Mapping Summary

7.7.1.1 Display Subsystem Register Mapping Summary

Table 7-119. Display Subsystem Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address

7.7.2 Display Subsystem Register Descriptions

7.7.2.1 Display Subsystem Registers

Table 7-128. DSS_REVISIONNUMBER

Address Offset	0x000	Physical address	0x4805 0000	Instance	DISS
Description	This register contains the display subsystem revision number.				
Type	R				

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																													REV		

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Read returns 0.	R	0x0000000
7:0	REV	Revision number [7:4] Major revision [3:0] Minor revision	R	TI internal data

Table 7-129. Register Call Summary for Register DSS_REVISIONNUMBER

Display Subsystem Register Manual

- [Display Subsystem Register Mapping Summary: \[0\]](#)

Table 7-130. DSS_SYSCONFIG

Address Offset	0x010
Physical address	0x4805 0010
Instance	DISS
Description	This register controls the various parameters of the interconnect interface.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																								Reserved	Reserved	SOFTRESET	AUTOIDLE				

Bits	Field Name	Description	Type	Reset
31:5	Reserved	Write 0s for future compatibility. Reads return zero.	RW	0x00000000
4:3	Reserved	Reserved. Keep at reset value.	RW	0x0
2	Reserved	Write 0s for future compatibility . Reads return zero.	RW	0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset	RW	0
0	AUTOIDLE	Enable power management capability 0x0: OCP clock is free-running 0x1: Automatic OCP clock gating strategy is applied based on the OCP interface activity	RW	1

RW	0
11	STALLMODE	Stall mode for the LCD output wr: VFP 0x0: Normal mode selected 0x1: Stall mode selected. The Display Controller sends the data without considering the VSYNC/HSYNC. The LCD output is disabled at the end of the transfer of the frame. The S/W has to re-enable the LCD output to generate a new frame. The stall mode is used in RFBI and DSI command modes.	RW	0
10	Reserved	Reserved for non-GP devices	RW	0
9:8	TFTDATALINES	Number of lines of the LCD interface WR: VFP 0x0: 12-bit output aligned on the LSB of the pixel data interface 0x1: 16-bit output aligned on the LSB of the pixel data interface 0x2: 18-bit output aligned on the LSB of the pixel data interface 0x3: 24-bit output aligned on the LSB of the pixel data interface	RW	0x0

Bits	Field Name	Description	Type	Reset
7	STDITHERENABLE	Spatial temporal dithering enable WR: VFP 0x0: Spatial/temporal dithering logic disabled 0x1: Spatial/temporal dithering logic enabled	RW	0
6	GODIGITAL	Digital GO Command 0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) associated with the digital output using the user values. The hardware resets the bit when the update is completed. 0x1: Users have finished programming the shadow registers of the pipeline(s) associated with the digital output and the hardware can update the internal registers at the external VSYNC.	RW	0
5	GOLCD	LCD GO Command 0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the LCD output using the user values. The hardware resets the bit when the update is completed. 0x1: Users have finished programming the shadow registers of the pipeline(s) associated with the LCD output and the hardware can update the internal registers at the VFP start period.	RW	0
4	M8B	Mono 8-bit mode WR: VFP 0x0: Pixel data [3:0] is used to output four pixel values to the panel at each pixel clock transition (only in Passive Mono 8-bit mode). 0x1: Pixel data [7:0] is used to output eight pixel values to the panel each pixel clock transition (only in Passive Mono 8-bit mode).	RW	0
3	STNTFT	LCD display type WR: VFP 0x0: Passive or Passive Matrix display operation enabled. Passive Matrix dither logic enabled. 0x1: Active Matrix display operation enabled. Passive Matrix Dither logic and output FIFO bypassed.	RW	0
2	MONOCOLOR	Monochrome/Color WR: VFP 0x0: Color operation enabled (Passive Matrix mode only) 0x1: Monochrome operation enabled (Passive Matrix mode only)	RW	0
1	DIGITALENABLE	Digital enable 0x0: Digital output disabled (at the end of the current field if interlace output when the bit is reset) 0x1: Digital output enabled	RW	0
0	LCDENABLE	LCD enable 0x0: LCD output disabled (at the end of the frame when the bit is reset) 0x1: LCD output enabled	RW	0

Bits	Field Name	Description	Type	Reset
31: 20	Reserved	Write 0s for future compatibility. Read returns 0	RW	0x00000
19	TVALPHABLENDERENABLE	Selects the alpha blender (TV output) 0x0: Alpha blender is disabled. 0x1: The alpha blender is enabled.	RW	0
18	LCDALPHABLENDERENABLE	Selects the alpha blender (LCD output) 0x0: Alpha blender is disabled. 0x1: The alpha blender is enabled.	RW	0
17	FIFOFILLING	Controls if the FIFO are refilled only when the LOW threshold is reached or if all FIFO are refilled when at least one of them reaches the LOW threshold. 0x0: Each FIFO is refilled when it reaches LOW threshold. 0x1: All FIFOs are refilled up to high threshold when at least one of them reaches the LOW threshold. (only active FIFOs should be considered and when reaching the end of the frame the FIFO goes to empty condition so no need to fill it again).	RW	0
16	FIFOHANDCHECK	Controls the handshake between FIFO and RFBI STALL to prevent from underflow. The bit should be set to 0 when the module is not in STALL mode. 0x0: Only the STALL signal from RFBI is used regardless of the FIFO fullness information to provide data to the RFBI module. 0x1: The STALL signal from RFBI is used in combination with the FIFO fullness information to provide data to the RFBI module only when it does not generated FIFO underflow.	RW	0
15	CPR	Color phase rotation control wr: VFP 0x0: Color phase rotation disabled 0x1: Color phase rotation enabled	RW	0
14	FIFOMERGE	FIFO merge control wr: EVSYNC or VFP 0x0: FIFO merge disabled Each FIFO is dedicated to one pipeline.	RW	0

Display Subsystem Register Manual

www.ti.com

Bits	Field Name	Description	Type	Reset
		0x1: FIFO merge enabled All the FIFOs are merged into a single one to be used by the single active pipeline.		
13	TCKDIGSELECTION	Transparency color key selection (digital output) wr: EVSYNC 0x0: Graphics destination transparency color key selected in normal mode or graphics source transparency color key selected in alpha mode 0x1: Video source transparency color key selected in normal mode	RW	0
12	TCKDIGENABLE	Transparency color key enabled (digital output) wr: EVSYNC 0x0: Disable the transparency color key for digital output 0x1: Enable the transparency color key for digital output	RW	0
11	TCKLCDSELECTION	Transparency color key selection (LCD output) WR: VFP 0x0: Graphics destination transparency color key selected in normal mode or graphics source transparency color key selected in alpha mode 0x1: Video source transparency color key selected in normal mode	RW	0
10	TCKLCDENABLE	Transparency color key enabled (LCD output) WR: VFP * 0x0: Disable the transparency color key for the LCD 0x1: Enable the transparency color key for the LCD	RW	0
9	FUNCGATED	Functional clocks gated enabled WR: immediate 0x0: Functional clocks gated disabled 0x1: Functional clocks gated enabled	RW	0
8	ACBIASGATED	ACBias Gated Enabled WR: VFP 0x0: AcBias Gated Disabled 0x1: AcBias Gated Enabled	RW	0
7	VSYNCGATED	VSYNC Gated Enabled WR: VFP 0x0: VSYNC Gated Disabled 0x1: VSYNC Gated Enabled	RW	0
6	HSGNGATED	HSGNGATED Enabled WR: VFP 0x0: HSGNGATED Disabled 0x1: HSGNGATED Enabled	RW	0
5	PIXELCLOCKGATED	Pixel Clock Gated Enabled WR: VFP 0x0: Pixel Clock Gated Disabled 0x1: Pixel Clock Gated Enabled	RW	0
4	PIXELDATAGATED	Pixel Data Gated Enabled WR: VFP 0x0: Pixel Data Gated Disabled 0x1: Pixel Data Gated Enabled	RW	0
3	PALETTEGAMMATABLE	Palette/Gamma Table selection WR: EVSYNC or VFP 0x0: LUT used as palette (only if graphics format is BITMAP1, 2, 4, and 8) 0x1: LUT used as gamma table (only if graphics format is NOT BITMAP1, 2, 4, and 8 or no graphics window present)	RW	0

Bits	Field Name	Description	Type	Reset
2:1	LOADMODE	Loading Mode for the Palette/Gamma Table WR: EVSYNC or VFP 0x0: Palette/Gamma Table and data are loaded every frame. 0x1: Palette/Gamma Table to be loaded. Users set the bit when the palette/gamma table has to be loaded. H/W resets the bit when table has been loaded. <code>(DISPC_GFX_ATTRIBUTES.GfxEnable</code> has to be set to 1). 0x2: Frame data only loaded every frame 0x3: Palette/Gamma Table and frame data loaded on first frame then switch to 10 (H/W).	RW	0x0
0	PIXELGATED	Pixel Gated Enable (only for Active Matrix Display) WR: VFP 0x0: Pixel clock always toggles (only in Active Matrix mode) 0x1: Pixel clock only toggles when there is valid data to display. (only in Active Matrix mode)	RW	0

Address Offset	0x0A0	Physical address	0x4805 04A0	Instance	DISC
Description	The register configures the graphics attributes. Shadow register, updated on VFP start period or EVSYNC.				
Type	RW				

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	PREMULTIPLYALPHA	RESERVED												GFXSELFREFRESH	GFXARBITRATION	GFXROTATION	GFXFIFOPRELOAD	GFXENDIANNESS	GFXNIBBLEMODE	GFXCHANNELOUT	GFXBURSTSIZE	GFXREPLICATIONENABLE	GFXFORMAT	GFXENABLE							

Bits	Field Name	Description	Type	Reset
31:29	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x000000
28	PREMULTIPLYALPHA	The field configures the DISPC GFX to process incoming data as pre-multiplied alpha data or non premultiplied alpha data. Default setting is non pre-multiplied alpha data. 0x0: Non pre-multiplyalpha data color component 0x1: Pre-multiplyalpha data color component	RW	0
<hr/>				
NOTE: The pre-multiplied alpha option is only valid when bit field [4:1] GFXFORMAT is set to ARGB or RGBA formats. Otherwise, the PREMULTIPLYALPHA bit field is ignored by the hardware.				
27:16	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x000000
15	GFXSELFREFRESH	Enables the self refresh of the graphics window from its own FIFO only. 0x0: The graphics pipeline accesses the interconnect to fetch data from the system memory 0x1: The graphics pipeline does not need anymore to fetch data from memory. Only the graphics FIFO is used. It takes effect after the frame has been loaded in the FIFO	RW	0

Display Subsystem Register Manual

www.ti.com

Bits	Field Name	Description	Type	Reset
14	GFXARBITRATION	Determines the priority of the graphics pipeline. The graphics pipeline is one of the high priority pipeline. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The graphics pipeline is one of the normal priority pipeline. 0x1: The graphics pipeline is one of the high priority pipeline.	RW	0
13:12	GFXROTATION	Graphics rotation flag (used only in case of RGB24 packed format) 0x0: No rotation 0x1: Rotation by 90 degrees 0x2: Rotation by 180 degrees 0x3: Rotation by 270 degrees	RW	0x0
11	GFXFIFOPRELOAD	Graphics preload value 0x0: H/W prefetches pixels up to the preload value defined in the preload register. 0x1: H/W prefetches pixels up to high threshold value.	RW	0
10	GFXENDIANNESS	Graphics endianness 0x0: Little endian operation is selected. 0x1: Big endian operation is selected.	RW	0
9	GFXNIBBLEMODE	Graphics Nibble Mode (only for 1-, 2- and 4-BPP) 0x0: Nibble mode is disabled 0x1: Nibble mode is enabled	RW	0
8	GFXCHANNELOUT	Graphics Channel Out configuration wr: immediate 0x0: LCD output selected 0x1: 24-bit output selected	RW	0
7:6	GFXBURSTSIZE	Graphics DMA Burst Size 0x0: 4x32bit bursts 0x1: 8x32bit bursts 0x2: 16x32bit bursts 0x3: Reserved	RW	0x0
5	GFXREPLICATION ENABLE	GfxReplicationEnable 0x0: Disable Graphics replication logic 0x1: Enable Graphics replication logic	RW	0
4:1	GFXFORMAT	Graphics format; Other enums: Reserved (0x7, 0xA, 0xB and 0xF) 0x0: BITMAP 1 (CLUT) 0x1: BITMAP 2 (CLUT) 0x2: BITMAP 4 (CLUT) 0x3: BITMAP 8 (CLUT) 0x4: RGB 12 (un-packed in 16-bit container) 0x5: ARGB16 0x6: RGB 16 0x8: RGB 24 (un-packed in 32-bit container) 0x9: RGB 24 (packed in 24-bit container) 0xC: ARGB32 0xD: RGBA32 0xE: RGBx 32 (24-bit RGB aligned on MSB of the 32-bit container)	RW	0x0
0	GFXENABLE	GfxEnable	RW	0

Bits	Field Name	Description	Type	Reset
	0x0:	Graphics disabled (graphics pipeline inactive and graphics window not present)		
	0x1:	Graphics enabled (graphics pipeline active and graphics window present on the screen)

Table 7-202. DISPC_VIDn_ATTRIBUTES

Address Offset	0x0CC+ ((-1)* 0x90)	Index	n = 1 for VID1 or 2 for VID2
Physical address	0x4805 04CC 0x4805 04CC 0x4805 055C 0x4805 055C	Instance	Display Controller Display Controller VID1 Display Controller Display Controller VID2
Description	The register configures the attributes of video window #n such as format, resizeable, shadow register, updated on VFP start period, or EVSYNC.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	PREMULTIPLYALPHA	RESERVED	VIDSELFREFRESH	VIDARBITRATION	VIDLINEBUFFERSPLIT	VIDVERTICALTAPS	VIDDMAOPTIMIZATION	VIDFIFOLOAD	VIDROWREPATENABLE	VIDCHANNELOUT	VIDDIANNESS	VIDBURSTSIZE	VIDROTATION	VIDFULLRANGE	VIDREPLICATIONENABLE	VIDCOLORCONVENABLE	VIDVRESIZECONF	VIDHRESIZECONF	VIDRESIZEENABLE	VIDFORMAT	VIDENABLE										

Bits	Field Name	Description	Type	Reset
31: 29	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0000
28	PREMULTIPLYALPHA	The field configures the DISPC VID2 to process incoming data as pre-multiplied alpha data or non pre-multiplied alpha data. Default setting is non pre-multiplied alpha data. 0x0: Non pre-multiplyalpha data color component 0x1: Premultiplyalpha data color component	RW	0
<p>NOTE: The pre-multiplied alpha control is supported only on VID2. For VID1 this bitfield is RESERVED. The pre-multiplied alpha option is only valid when bit field [4:1] VIDFORMAT is set to ARGB or RGBA formats. Otherwise, the PREMULTIPLYALPHA bit field is ignored by the hardware.</p>				
27: 25	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0000
24	VIDSELFREFRESH	Enables the self refresh of the video window from its own FIFO only. 0x0: The video pipeline accesses the interconnect to fetch data from the system memory 0x1: The video pipeline does not need anymore to fetch data from memory. Only the video FIFO is used. It takes effect after the frame has been loaded in the FIFO	RW	0
23	VIDARBITRATION	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The video pipeline is one of the normal priority pipeline. 0x1: The video pipeline is one of the high priority pipeline.	RW	0
22	VIDLINEBUFFER SPLIT	Video vertical line buffer split 0x0: Vertical line buffers are not split. 0x1: Vertical line buffers are split into two.	RW	0
21	VIDVERTICALTAPS	Video vertical resize tap number 0x0: Three taps are used for the vertical filtering logic. The other two taps are not used. 0x1: Five taps are used for the vertical filtering logic.	RW	0
20	VIDDMAOPTIMIZATION	Video optimization in case of 0x0: The DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory). 0x1: The DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory). The bit field [21] VIDVERTICALTAPS shall be set to 0x1, bit field [22] VIDLINEBUFFERSPLIT to 0x1, and all scaler registers shall be configured even for 1:1 ratio. Even width is required for the input picture when 5 taps are used.	RW	0
19	VIDFIFOPRELOAD	Video preload value 0x0: H/W prefetches pixels up to the preload value defined in the preload register.	RW	0

Display Subsystem Register Manual

www.ti.com

Bits	Field Name	Description	Type	Reset
		0x1: H/W prefetches pixels up to the high threshold value.		
18	VIDROWREPEAT ENABLE	Video Row Repeat (YUV case only when rotating 90 or 270-degree) 0x0: Row of VIDn won't be read twice. 0x1: The Row data are fetched twice to extract both the Y components	RW	0
17	VIDENDIANNESS	Video Endianness 0x0: Little endian operation is selected. 0x1: Big endian operation is selected.	RW	0
16	VIDCHANNELOUT	Video Channel Out configuration wr: Immediate 0x0: LCD output selected 0x1: 24 bit output selected	RW	0
15:14	VIDBURSTSIZE	Video DMA Burst Size 0x0: 4x32bit bursts 0x1: 8x32bit bursts 0x2: 16x32bit bursts 0x3: Reserved	RW	0x0
13:12	VIDROTATION	Video Rotation Flag 0x0: No rotation or VidFormat is RGB 0x1: Rotation by 90 degrees 0x2: Rotation by 180 degrees 0x3: Rotation by 270 degrees	RW	0x0
11	VIDFULLRANGE	VidFullRange 0x0: Limited range selected: 16 subtracted from Y before color space conversion 0x1: Full range selected: Y is not modified before the color space conversion	RW	0
10	VIDREPLICATION ENABLE	VidReplicationEnable 0x0: Disable Video replication logic 0x1: Enable Video replication logic	RW	0
9	VIDCOLORCONV ENABLE	VidColorConvEnable 0x0: Disable Color Space Conversion CbYCr to RGB 0x1: Enable Color Space Conversion CbYCr to RGB	RW	0
8	VIDVRESIZECONF	Video Vertical Resize Configuration 0x0: Up-sampling selected 0x1: Down-sampling selected	RW	0
7	VIDHRESIZECONF	Video Horizontal Resize Configuration 0x0: Up-sampling selected 0x1: Down-sampling selected	RW	0
6:5	VIDRESIZEENABLE	Video Resize Enable 0x0: Disable the resize processing 0x1: Enable the horizontal resize processing 0x2: Enable the vertical resize processing 0x3: Enable both horizontal and vertical resize processing	RW	0x0
4:1	VIDFORMAT (Video 1 channel)	Video1 channel Format; Other enums: Reserved (all other values between 0x0 and 0x3, 0x5, 0x7, and between 0xC and 0xF) 0x4: RGB12 (16-bit container) 0x6: RGB 16 0x8: RGB 24 (unpacked in 32-bit container)	RW	0x0

Bits	Field Name	Description	Type	Reset
		0x9: RGB 24 (packed in 24-bit container) 0xA: YUV2 4:2:2 co-sited 0xB: UYVY 4:2:2 co-sited		
	VIDFORMAT (Video 2 channel)	Video2 channel Format; Other enums: Reserved (all other values: 0x0 and 0x3, 0x7, and 0xF) 0x4: RGB 12 (16-bit container) 0x5: ARGB 16 0x6: RGB 16 0x8: RGB 24 (un-packed in 32-bit container) 0x9: RGB 24 (packed in 24-bit container) 0xA: YUV2 4:2:2 co-sited 0xB: UYVY 4:2:2 co-sited 0xC: ARGB 32 0xD: RGBA 32 0xE: RGBx 32 (24-bit RGB aligned on MSB of the 32-bit container)	RW	0x0
0	VIDENABLE	VidEnable 0x0: Video disabled (video pipeline inactive and window not present) 0x1: Video enabled (video pipeline active and window present on the screen)	RW	0

Table 7-252. RFBI_CONTROL

Address Offset	0x40	Physical address	0x4805 0840	Instance	RFBI
Description	The control register allows configuration of the RFBI module.				
Type	RW				
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0		
RESERVED					ENABLE
					CONFIGSELECT
					BYPASSMODE
					ITE
					HIGHTHRESHOLD
					DISABLE_DMA_REQ
					SMART_DMA_REQ

Display Subsystem Register Manual

www.ti.com

Bits	Field Name	Description	Type	Reset
31: 9	Reserved	Write 0s for future compatibility Read returns 0	RW	0x00000000
8	SMART_DMA_REQ	Smart DMA request 0x0: The dmareq is asserted and de-asserted depending on the interconnect FIFO space even if Mldlereq is high in smart idle/no-idle mode and the entire burst gets error responses from the module. 0x1: The dmareq is de-asserted after 2 clk cycles if it has been asserted for more than or equal to 2 clk cycles and Mldlereq is high in smart idle or no idle mode. No more burst requests will be given even if the space is available in the interconnect FIFO.	RW	0x0
7	DISABLE_DMA_REQ	Disable DMA request 0x0: The dmareq is enabled and the signal is generated based on the space available and the request coming into the data register. 0x1: The dmareq is disabled and the signal is not generated at all based on space in the interconnect FIFO. It stays high until the DISABLE DMAREQ is high even if there is space in the interconnect FIFO to take requests.	RW	0x0
6:5	HIGHTHRESHOLD	Defines the interconnect FIFO high threshold used by HW to assert DMA request. Used only if data written to RFBI_DATA are sent using system DMA. 0x0: Size of the transfer of 4 words of 32-bit wide 0x1: Size of the transfer of 8 words of 32-bit wide 0x2: Size of the transfer of 16 words of 32-bit wide	RW	0x0
4	ITE	Internal Trigger 0: H/W waits for ITE bit to be set if in internal trigger mode for the configuration in use. 1: User sets the ITE bit to start the transfer, when H/W takes into account the bit, the H/W resets it.	RW	0
3:2	CONFIGSELECT	Select the CS and configuration 00: No CS selected 01: CS0 selected and configuration #0 10: CS1 selected and configuration #1 11: CS0 and CS1 both selected (only the configuration for CS0 is used)	RW	0x0
1	BYPASSMODE	Bypass Mode 0: The bypass mode not selected 1: The bypass mode is selected	RW	1
0	ENABLE	Enable/Disable flag 0: Disable the RFBI module 1: Enable the RFBI module	RW	0

7.7.2.4 Video Encoder Registers

Table 7-284. VENC_REV_ID

Address Offset	0x00		
Physical address	0x4805 0C00	Instance	VENC
Description	Revision ID for the encoder		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																								REV_ID							

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Reserved. Read returns 0s.	R	0x000000
7:0	REV_ID	This read-only register contains the revision ID for the encoder. The revision ID will identify different revisions of the IP.	R	TI internal data

Table 7-286. VENC_STATUS

Address Offset	0x04		
Physical address	0x4805 0C04	Instance	VENC
Description	VENC_STATUS		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																									CCE	CCO	FSQ				

Bits	Field Name	Description	Type	Reset
31:5	Reserved	Reserved. Read returns 0s.	R	0x00000000
4	CCE	Closed caption status for even Field. This bit is set immediately after the data in registers LINE21_E0 and LINE21_E1 have been encoded to closed caption. This bit is reset when both of these registers are written.	R	0
3	CCO	Closed Caption Status for Odd Field. This bit is set immediately after the data in registers LINE21_O0 and LINE21_O1 have been encoded to closed caption. This bit is reset when both of these registers are written.	R	0
2:0	FSQ	Field Sequence ID. For PAL, all three FSQ[2:0] are used whereas for NTSC only FSQ[1:0] is meaningful. Furthermore, FSQ[0] represents odd field when it is 0 and even field when it is 1. Read 0x0: Odd field Read 0x1: Even field	R	0x0

Table 7-288. VENC_F_CONTROL

Address Offset	0x08	Physical address	0x4805 0C08	Instance	VENC
Description	This register specifies the input video source and format				
Type	RW				

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																									RESET	SVDS	RGBF	BCOLOR	FMT		

Bits	Field Name	Description	Type	Reset
31:9	Reserved	Reserved. Read returns 0s.	RW	0x000000
8	RESET	RESET the encoder 0x0: No effect 0x1: Reset the encoder, after reset, this bit is automatically set to zero.	RW	0
7:6	SVDS	Select Video Data Source. 0x0: Use external video source 0x1: Use internal Color BAR 0x2: Use background color 0x3: Reserved	RW	0x2
5	RGBF	RGB/YCrCb input coding range 0x0: The input RGB data are in binary format with coding range 0-255 The input YCrCb data are in binary format with coding range 0-255 0x1: The input RGB data are in binary format with coding range 16-235 The input YCrCb data are in binary format conforming to ITU-601 standard	RW	0
4:2	BCOLOR	Background color select 0x0: black 0x1: blue 0x2: red 0x3: magenta 0x4: green 0x5: cyan 0x6: yellow 0x7: white	RW	0x1
1:0	FMT	These two bits specify the video input data stream format and timing 0x0: 24-bit 4:4:4 RGB 0x1: 24-bit 4:4:4 0x2: 16-bit 4:2:2 0x3: 8-bit ITU-R 656 4:2:2	RW	0x3

Address Offset	0x58																						
Physical address	0x4805 0C58																						
Description	VENC_LN_SEL																						
Type	RW																						
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0																				
Reserved	LN21_RUNIN							Reserved				SLINE											
Bits	Field Name	Description													Type	Reset							
31:26	Reserved	Reserved. Read returns 0s.													RW	0x00							
25:16	LN21_RUNIN	The two bytes of the closed caption run in code position from the HSYNC.													RW	0x10B							
15:5	Reserved	Reserved. Read returns 0s.													RW	0x000							
4:0	SLINE	Selects the line where closed caption or extended service data are encoded. The value of the SLINE[4:0] bit field depends on the video standard: PAL mode: Because there is a one-line offset, program the desired line number – 1. To activate the closed caption on line 21 (0x15), program the value 0x15 – 1 = 0x14. The default value is 0x15 + 1 = 0x16 (line 22). NTSC mode: Because there is a four-line offset, program the desired line number – 4. To activate the closed caption on line 21 (0x15), program the value 0x15 – 4 = 0x11. The default value is 0x15 + 4 = 0x19 (line 25).													RW	0x15

Table 7-366. VENC_OUTPUT_CONTROL

Address Offset	0x0000 00C4	Physical Address	0x4805 0CC4 <th>Instance</th> <td>VENC</td>	Instance	VENC
Description	Output channel control register Also contains some test control features				
Type	RW				
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0		
RESERVED	LUMA_TEST	RESERVED	CHROMA_SOURCE COMPOSITE_SOURCE LUMA_SOURCE TEST_MODE VIDEO_INVERT CHROMA_ENABLE COMPOSITE_ENABLE LUMA_ENABLE		

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	Reserved. Read returns 0s.	RW	0x00
25:16	LUMA_TEST	In test mode, DAC 1 input value (if s-video video mode is selected)	RW	0x000
15:8	RESERVED	Reserved. Read returns 0s.	RW	0x00
7	CHROMA_SOURCE	Source of chroma video data in test mode 0x0: Chroma test data comes from internal register OUTPUT_TEST[25:16] 0x1: Chroma test data comes from display controller video port G[1:0], B[7:0]	RW	0x0
6	COMPOSITE_SOURCE	Source of composite video data in test mode 0x0: Composite test data comes from internal register OUTPUT_TEST[9:0] 0x1: Composite test data comes from display controller video port G[1:0], B[7:0]	RW	0x0

Bits	Field Name	Description	Type	Reset
5	LUMA_SOURCE	Source of luminance video data in test mode 0x0: Luma test data comes from internal register OUTPUT_CONTROL[25:16] 0x1: Luma test data comes from display controller video port G[1:0], B[7:0]	RW	0x0
4	TEST_MODE	This enables the video DACs to be tested. The values sent to the DACs comes from a register for each output channel (Luma, Composite or Chroma) or from the display controller video port bits G[1:0], B[7:0], depending on the setting of the Source bits 0x0: Video outputs are in normal operation 0x1: Test mode. Video outputs are directly connected to either internal registers or the display controller video port.	RW	0x0
3	VIDEO_INVERT	Controls the video output polarity. This may be used to correct for inversion in an external video amplifier. 0x0: Video outputs are inverted 0x1: Video outputs are normal polarity	RW	0x1
2	CHROMA_ENABLE	Enable the Chrominance output channel 0x0: Chroma output is disabled 0x1: Chroma output is enabled	RW	0x0
1	COMPOSITE_ENABLE	Enable the Composite output channel 0x0: Composite output is disabled 0x1: Composite output is enabled	RW	0x0
0	LUMA_ENABLE	Enable the Luminance output channel 0x0: Luma output is disabled 0x1: Luma output is enabled	RW	0x0

15	LP_RX_TO_IRQ	Interrupt for Low Power Rx Time out 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
14	HS_TX_TO_IRQ	Interrupt for high-speed Tx Time out. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
13	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
12:11	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
10	COMPLEXIO_ERR_IRQ	Error signaling from complex I/O: status of the complex I/O errors received from the complex I/O(events are defined in DSI_COMPLEXIO_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0
9	PLL_RECAL_IRQ	PLL recalibration event (assertion of recalibration signal from the DSI PLL Control module) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
8	PLL_UNLOCK_IRQ	PLL un-lock event (de-assertion of lock signal from the DSI PLL Control module) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
7	PLL_LOCK_IRQ	PLL lock event (assertion of lock signal from the DSI PLL Control module) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
6	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
5	RESYNCHRONIZATION_IRQ	Video mode resynchronization Indicates that the video port works but the configuration of the timings for the display controller (DISPC) and for DSI protocol engine may have to be modified to avoid the resynchronization to occur. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
4	WAKEUP_IRQ	Wakeup 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
3	VIRTUAL_CHANNEL3_IRQ	Virtual channel #3 Error signaling from DSI Virtual Channel3: Status of DSI Virtual Channel3 errors received from DSI Virtual Channel3 (events are defined in DSI_VC3_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0
2	VIRTUAL_CHANNEL2_IRQ	Virtual channel #2 Error signaling from DSI Virtual Channel2: Status of DSI Virtual Channel2 errors received from DSI Virtual Channel2 (events are defined in DSI_VC2_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0
1	VIRTUAL_CHANNEL1_IRQ	Virtual channel #1 Error signaling from DSI Virtual Channel1: Status of DSI Virtual Channel1 errors received from DSI Virtual Channel1 (events are defined in DSI_VC1_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0
0	VIRTUAL_CHANNEL0_IRQ	Virtual channel #0 Error signaling from DSI Virtual Channel0: Status of the DSI Virtual Channel0 errors received from DSI Virtual Channel0 (events are defined in DSI_VC0_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0

Table 7-380. DSI_CTRL

Address Offset	0x0000 0040		Physical Address	0x4804 FC40		Instance	DSI_PROTOCOL_ENGINE	
Description	GLOBAL CONTROL REGISTER This register controls the DSI Protocol Engine module. This register should not be modified dynamically (except IF_EN bit field).							
Type	RW							

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																										
					RESERVED			RGB565_ORDER		DCS_CMD_CODE		DCS_CMD_ENABLE		HSA_BLANKING_MODE		HBP_BLANKING_MODE		HFP_BLANKING_MODE		BLANKING_MODE		EOT_ENABLE		VP_HSYNC_END		VP_HSYNC_START		VP_VSYNC_END		VP_VSYNC_START		TRIGGER_RESET_MODE		LINE_BUFFER		VP_VSYNC_POL		VP_HSYNC_POL		VP_DE_POL		VP_CLK_POL		VP_DATA_BUS_WIDTH		TRIGGER_RESET		VP_CLK_RATIO		TX_FIFO_ARBITRATION		ECC_RX_EN		CS_RX_EN		IF_EN	

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
26	RGB565_ORDER	Byte order for RGB565 command mode from video port 0x0: 0x1: Byte order as for video mode	RW	0
25	DCS_CMD_CODE	DCS command code value to insert between header and video port data when enabled by DCS_CMD_ENABLE 0x0: DCS write memory continue code is inserted. 0x1: DCS write memory start code is inserted.	RW	0
24	DCS_CMD_ENABLE	Enables automatic insertion of DCS command codes when data is sourced by the video port. 0x0: DCS command code is not inserted when command mode traffic is coming from the Video Port. 0x1: DCS command code is inserted automatically when command mode traffic is coming from the Video Port.	RW	0
23	HSA_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HSA blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HSA blanking period of video mode.	RW	0x0
22	HBP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HBP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HBP blanking period of video mode.	RW	0x0

Bits	Field Name	Description	Type	Reset
21	HFP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HFP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HFP blanking period of video mode.	RW	0x0
20	BLANKING_MODE	Blanking mode 0x0: LPS is used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE and HFP_BLANKING_MODE bit fields respectively) when there is no command mode data in TX FIFO ready to be sent. So blanking periods can be different during the frame depending on the TX FIFO. 0x1: LONG BLANKING PACKETS are used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE and HFP_BLANKING_MODE bit fields respectively) regardless of the packets present in the TX FIFO ready to be sent	RW	0x0
19	EOT_ENABLE	Enable EOT packets at the end of HS transmission. 0x0: No EOT packets 0x1: EOT packet is sent at all HS to LP transitions	RW	0
18	VP_HSYNC_END	Hsync end pulse. 0x0: Disabled. No HSYNC END short packet is generated. 0x1: Enabled. While the HSYNC END pulse is detected, the associated short packet HSYNC END is generated.	RW	0x0
17	VP_HSYNC_START	Hsync start pulse. 0x0: Disabled. No HSYNC START short packet is generated. 0x1: Enabled. While the HSYNC start pulse is detected, the associated short packet HSYNC START is generated.	RW	0x0
16	VP_VSYNC_END	Vsync end pulse. 0x0: Disabled. No VSYNC END short packet is generated. 0x1: Enabled. While the VSYNC END pulse is detected, the associated short packet VSYNC END is generated.	RW	0x0
15	VP_VSYNC_START	Vsync start pulse. 0x0: Disabled. No VSYNC START short packet is generated. 0x1: Enabled. While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated.	RW	0x0
14	TRIGGER_RESET_MODE	Selection of the trigger reset mode 0x0: Synchronized: the mode is only valid if there is VC using the video mode and it is active. The principle is to wait for the current video frame to be transferred on the link. Any data received after the VSYNC are ignored. 0x1: Immediate: all pending requests in TX FIFO are taken into account for transfer scheduling, the RX FIFO is ignored, and the data from video port are ignored as soon as possible. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.	RW	0x0
13:12	LINE_BUFFER	Number of line buffers to be used while receiving data on the video port. 0x0: No line buffer 0x1: 1 line buffer 0x2: 2 line buffers	RW	0x0
11	VP_VSYNC_POL	VP vertical synchronization signal polarity 0x0: VSYNC signal on the video port is active low. 0x1: VSYNC signal on the video port is active high.	RW	0x0

Display Subsystem Register Manual

www.ti.com

Bits	Field Name	Description	Type	Reset
10	VP_HSYNC_POL	VP horizontal synchronization signal polarity 0x0: HSYNC signal on the video port is active low. 0x1: HSYNC signal on the video port is active high.	RW	0x0
9	VP_DE_POL	VP data enable signal polarity 0x0: DE signal on the video port is active low. 0x1: DE signal on the video port is active high.	RW	0x0
8	VP_CLK_POL	VP pixel clock polarity 0x0: The DSI Protocol Engine module captures the data on the VP on the pixel clock falling edge. The module connected to the VP must drive the data on the pixel clock rising edge. 0x1: The DSI Protocol Engine module captures the data on the VP on the pixel clock raising edge. The module connected to the VP must drive the data on the pixel clock falling edge.	RW	0x1
7:6	VP_DATA_BUS_WIDTH	Defines the size of the video port data bus 0x0: 16-bits data width (LSB of the 24-bit video port data bus) 0x1: 18-bits data width (LSB of the 24-bit video port data bus) 0x2: 24-bits data width (LSB of the 24-bit video port data bus)	RW	0x0
5	TRIGGER_RESET	Send the reset trigger to the peripheral. 0x0: READS: Reset trigger generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the request for Reset trigger generation (maybe too late since it is already on going) 0x1: READS: Generation of the reset trigger has been requested by user (could be on going but not completed yet). WRITES: Request for Reset trigger to be sent to the peripheral.	RW	0x0
4	VP_CLK_RATIO	This bit indicates the clock ratio between VP_CLK and VP_PCLK. The clock VP_PCLK is generated from VP_CLK. It is divided down. The information is only used when the video port is used to provide data in command mode. In the case of video mode, it is not used. 0x0: The clock VP_PCLK is the clock VP_CLK divided by 2. The duty cycle of VP_PCLK is 50/50. 0x1: The clock VP_PCLK is the clock VP_CLK divided by 3 or more. The duty cycle of VP_PCLK is not 50/50 for odd ratio numbers (3,5,7,...).	RW	0x0
3	TX_FIFO_ARBITRATION	Defines the arbitration scheme for granting the VC pending ready requests in the TX FIFO 0x0: Round-Robin Scheme is used 0x1: Sequential Scheme is used	RW	0x0
2	ECC_RX_EN	Enables the ECC check for the received header (short and long packets for all VC IDs). 0x0: Disabled 0x1: Enabled	RW	0x0
1	CS_RX_EN	Enables the checksum check for the received payload (long packet only for all VC IDs). 0x0: Disabled 0x1: Enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
0	IF_EN	<p>Enables the module. When the module is disabled the signals from the complex I/O are gated (no updates of the interrupt status register).</p> <p>It is not possible to change the bit fields in the DSI_CTRL register, except IF_EN when it is enabled. All the other registers can be changed except the ones that require DSI_VCn_CTRL[0] VC_EN to be equal to 0 to be modified.</p> <p>0x0: The interface is disabled. If one of the VC uses the video mode with the video port to receive the data, the DSI protocol engines is disabled when the next VSYNC is received and all the data in the FIFO for the other VCs in command mode are sent to the peripherals (if BTA_EN bit is enabled, the DSI protocol engine needs to wait for the response and BTA from the peripheral before disabling all the internal logic since an acknowledgement is requested).</p> <p>0x1: The interface is enabled immediately, the data acquisition on the video port starts on the next VSYNC (video mode) or first data received in the Slave port FIFO (command mode).</p>	RW	0x0

Table 7-382. DSI_COMPLEXIO_CFG1

Address Offset	0x0000 0048															Instance	DSI_PROTOCOL_ENGINE																						
Physical Address	0x4804 FC48															Description	COMPLEXIO CONFIGURATION REGISTER for the complex I/O This register contains the lane configuration for the order and position of the lanes (clock and data) and the polarity order for the control of the PHY differential signals in addition to the control bit for the power FSM.																						
Type	RW																																						
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0							
SHADOWING											LDO_POWER_GOOD_STATE	USE_LDO_EXTERNAL	RESERVED	RESERVED	RESERVED	RESERVED	RESERVED	DATA2_POL	DATA2_POSITION	DATA1_POL	DATA1_POSITION	CLOCK_POL	CLOCK_POSITION																
Bits	Field Name		Description																							Type	Reset												
31	SHADOWING		Shadowing configuration. 0x0: Disabled. The writes to the DSIPHY_CFG0 and DSIPHY_CFG1 registers are done like the other SCP registers. 0x1: Enabled. The writes to the DSIPHY_CFG0 and DSIPHY_CFG1 registers are done only when the GO bit is set and when the signal DISPC_UPDATE_SYNC from the display controller module is active.																							RW	0x0												
30	GOBIT		Allows the synchronized update of the shadow registers when the signal DISPC_UPDATE_SYNC is active. 0x0: Resets the Gobit. The hardware has finished the update of the shadow SCP registers. The bit is reset by Hardware. The software can reset the bit in case users decide to abort it. There is no guarantee that the software reset is done before the transfer of the values to the complex I/O. 0x1: Set the Gobit. Only when the transfer of the new values for the two first registers is completed (2, 1, or 0 transfers are performed based on the number of registers to update), the GObit is reset. The DISPC_UPDATE_SYNC signal is used to synchronize the update. The bit must be set only when it is in reset state.																						RW	0													
29	RESET_DONE		Internal reset monitoring of the power domain using the TxByteClkHS from the complex I/O 0x0: Internal module reset is on going. 0x1: Reset completed.																						R	1													
28:27	PWR_CMD		Command for power control of the complex I/O 0x0: Command to change to OFF state 0x1: Command to change to ON state 0x2: Command to change to ultralow-power state																						RW	0x0													
26:25	PWR_STATUS		Status of the power control of the complex I/O 0x0: complex I/O in OFF state 0x1: complex I/O in ON state 0x2: complex I/O in ultralow-power state																						R	0x0													
24:22	RESERVED		Write 0s for future compatibility. Reads returns 0.																						RW	0x0													

Bits	Field Name	Description	Type	Reset
21	LDO_POWER_GOOD_STATE	Indicates the state of the signal LDOPWRGOOD. VDDALDODSIPLL: 1.2-V power supply for the PLL. The voltage is supplied by the internal or external LDO. The interrupt LDO_POWER_GOOD_IRQ is generated when a transition is detected on the signal LDOPWRGOOD from the DSI_PHY. 0x0: VDDALDODSIPLL power supply is down 0x1: VDDALDODSIPLL power supply is up	R	0x0
20	USE_LDO_EXTERNAL	Select the external LDO for the DSI_PHY. 0x0: DSI_PHY internal LDO is used. 0x1: External LDO is used. DSI_PHY LDO is tri-stated.	RW	0x0
19	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
18:16	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
15	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
14:12	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
11	DATA2_POL	+/- differential pin order of DATA lane 2. 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
10:8	DATA2_POSITION	Position and order of the DATA lane 2. 0x0: Not used/connected 0x1: Data lane 2 is at the position 1 (line 1). 0x2: Data lane 2 is at the position 2 (line 2). 0x3: Data lane 2 is at the position 3 (line 3). Other values: reserved	RW	0x0
7	DATA1_POL	+/- differential pin order of DATA lane 1 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
6:4	DATA1_POSITION	Position and order of the DATA lane 1. 0x1: Data lane 1 is at the position 1 (line 1). 0x2: Data lane 1 is at the position 2 (line 2). 0x3: Data lane 1 is at the position 3 (line 3). Other values: reserved	RW	0x0
3	CLOCK_POL	+/- differential pin order of CLOCK lane. 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
2:0	CLOCK_POSITION	Position and order of the CLOCK lane. The clock lane is always present. 0x1: Clock lane is at the position 1 (line 1). 0x2: Clock lane is at the position 2 (line 2). 0x3: Clock lane is at the position 3 (line 3). Other values: reserved	RW	0x0

PLL_PWR_CMD	PLL_PWR_STATUS	RESERVED																LP_CLK_DIVISOR							

Display Subsystem Register Manual

www.ti.com

Bits	Field Name	Description	Type	Reset
31:30	PLL_PWR_CMD	<p>Command for power control of the DSI PLL Control module</p> <p>0x0: Command to change to OFF state</p> <p>0x1: Command to change to ON state for PLL only (HSDIVISER is OFF)</p> <p>0x2: Command to change to ON state for both PLL and HSDIVISER</p> <p>0x3: Command to change to ON state for both PLL and HSDIVISER (no clock output to the DSI complex I/O)</p>	RW	0x0
29:28	PLL_PWR_STATUS	<p>Status of the power control of the DSI PLL Control module</p> <p>0x0: DSI PLL Control module in OFF state</p> <p>0x1: DSI PLL Control module in ON state for PLL only (HSDIVISER is OFF)</p> <p>0x2: DSI PLL Control module in ON state for both PLL and HSDIVISER</p> <p>0x3: DSI PLL Control module in ON state for both PLL and HSDIVISER (no clock output to the DSI complex I/O)</p>	R	0x0
27:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
21	LP_RX_SYNCHRO_ENABLE	<p>Defines if the DSI functional clock is higher or lower than 30 MHz. The information is used to define synchronization to be used for RxValidEsc.</p> <p>0x0: The DSI functional clock is equal or slower than 30 MHz. The synchronization is falling/rising.</p> <p>0x1: The DSI functional clock is higher than 30 MHz. The synchronization is rising/rising.</p>	RW	0x0
20	LP_CLK_ENABLE	<p>Controls the gating of the TXCLKESC clock.</p> <p>0x0: Disabled. The clock is not generated. The value of LP_CLK_DIVISOR[12:0] bit field is not used and does not have to be programmed.</p> <p>0x1: Enabled. The clock is generated. The value of LP_CLK_DIVISOR[12:0] bit field is used and must be programmed.</p>	RW	0x0
19	HS_MANUAL_STOP_CTRL	<p>In case HS_AUTO_STOP_ENABLE bit is set to 0 (reset value), the bit field allows manual control of the assertion/de-assertion of the signal DSIStrtClk by users.</p> <p>0x0: DSIStrtClk de-assertion unconditionally.</p> <p>0x1: DSIStrtClk assertion unconditionally.</p>	RW	0x0
18	HS_AUTO_STOP_ENABLE	<p>Enables the automatic assertion/de-assertion of DSIStrtClk signal.</p> <p>0x0: Auto mode disabled.</p> <p>0x1: Auto mode enabled.</p>	RW	0x0
17:16	LP_CLK_NULL_PACKET_SIZE	Indicates the size of LP NULL Packets to be sent automatically when after the last LP packet transfer. It is used by the receiver to drain its internal pipeline. The valid values are from 0 to 3 bytes for the payload size.	RW	0x0
15	LP_CLK_NULL_PACKET_ENABLE	<p>Enables the generation of NULL packet in low speed.</p> <p>0x0: Disabled. The NULL packet is not sent in LP mode after the last LP packet.</p> <p>0x1: Enabled. The NULL packet is sent in LP mode after the last LP packet.</p>	RW	0x0
14	CIO_CLK_ICG	<p>Controls the signal for gating the L3_ICLK clock provided to the complex I/O</p> <p>0x0: Disabled. The L3_ICLK clock to the DSI complex I/O is gated.</p> <p>0x1: Enabled. The L3_ICLK clock to the DSI complex I/O is not gated.</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
13	DDR_CLK_ALWAYS_ON	<p>Defines if the DDR clock is also sent when there is no HS packets sent to the peripheral (low power mode). So TXRequest for the clock lane is not de-asserted.</p> <p>0x0: Disabled. The DDR clock is only provided when HS packets are sent.</p> <p>0x1: Enabled. The DDR clock is always sent to the peripheral regardless of the state of the data lanes (HS or LP mode).</p>	RW	0x0
12:0	LP_CLK_DIVISOR	<p>Defines the ratio to be used for the generation of the low-power mode clock from DSI functional clock.</p> <p>The supported values are from 1 to 8191(the value 0 is invalid). The output frequency must be in the range between 20 MHz and 32 kHz.</p>	RW	0x0001

Table 7-390. DSI_TIMING1

Address Offset	0x0000 0058																																				
Physical Address	0x4804 FC58																Instance	DSI_PROTOCOL_ENGINE																			
Description	TIMING1 REGISTER This register controls the DSI Protocol Engine module timers. Any bit field can be modified while DSI_CTRL.IF_EN is set to 1. It is used to indicate the number of DSI_FCLK clock cycles for the timers FORCE_TX_STOP_TIMER and TA_TO_TIMER																																				
Type	RW																																				
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
TA_TO	TA_TO_X16	TA_TO_X8	TA_TO_COUNTER																FORCE_TX_STOP_MODE_IO	STOP_STATE_X16_IO	STOP_STATE_X4_IO	STOP_STATE_COUNTER_IO															

Display Subsystem Register Manual

www.ti.com

Bits	Field Name	Description	Type	Reset
31	TA_TO	Enables the turn-around timer 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0x0
30	TA_TO_X16	Multiplication factor for the number of DSI_FCLK clock cycles defined in TA_TO_COUNTER bit field 0x0: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 16x	RW	0x1
29	TA_TO_X8	Multiplication factor for the number of DSI_FCLK clock cycles defined in TA_TO_COUNTER bit field 0x0: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 8x	RW	0x1
28:16	TA_TO_COUNTER	Turn around counter. It indicates the number of DSI_FCLK clock cycles to wait for the change of the Direction PPI signal according to the TurnRequest signal The value is from 0 to 8191.	RW	0x1FFF
15	FORCE_TX_STOP_MODE_IO	Control of ForceTxStopMode signal 0x0: De-assertion of ForceTxStopMode. The hardware reset the bit at the end of the ForceTXStopMode assertion. The SW can reset the bit to stop the assertion of the ForceTXStopMode signal prior to the completion of the period. 0x1: Assertion of ForceTxStopMode	RW	0x0
14	STOP_STATE_X16_IO	Multiplication factor for the number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO bit field 0x0: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 16x	RW	0x1
13	STOP_STATE_X4_IO	Multiplication factor for the number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO bit field 0x0: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 4x	RW	0x1
12:0	STOP_STATE_COUNTER_IO	Stop state counter. It indicates the number of DSI_FCLK clock cycles to assert ForceTXStopMode signal. The value is from 0 to 8191.	RW	0x1FFF

31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
RESERVED	WINDOW_SYNC	VSA	VFP

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
27:24	WINDOW_SYNC	Number of TxByteClkHS clock cycles for the synchronization window. An interrupt for synchronization lost is generated when the received synchronization on video port is not inside the window. The DSI protocol engine does not change its own timings if the synch is inside the window. The valid values are from 0 to 15.	RW	0x0
23:16	VSA	Defines the vertical Sync active period used in video mode in number of lines. The supported values are from 0 to 255 It is used to generate the short packet for End of Vertical synchronization.	RW	0x00
15:8	VFP	Defines the vertical front porch used in video mode in number of lines. The supported values are from 0 to 255	RW	0x00
7:0	VBP	Defines the vertical back porch used in video mode in number of lines. The supported values are from 0 to 255	RW	0x00

Table 7-400. DSI_CLK_TIMING

Address Offset	0x0000 006C																				
Physical Address	0x4804 FC6C																				
Description	CLOCK TIMING REGISTER This register controls the DSI Protocol Engine module timers. This register should not be modified while DSI_CTRL.IF_EN is set to 1.																				
Type	RW																				
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0																		
RESERVED								DDR_CLK_PRE				DDR_CLK_POST									
Bits	Field Name	Description																			
31:16	RESERVED	Write 0s for future compatibility. Reads returns 0.																			
15:8	DDR_CLK_PRE	Indicates the number of TxByteClkHS cycles between the start of the DDR clock and the assertion of the data request signal. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON is set to 1 since the DDR clock is always present.																			
7:0	DDR_CLK_POST	Indicates the number of TxByteClkHS cycles after the de-assertion of the data request signal and the stop of the DDR clock. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON is set to 1 since the DDR clock is always present.

Table 7-406. DSI_COMPLEXIO_CFG2

Address Offset	0x0000 0078															Instance	DSI_PROTOCOL_ENGINE															
Physical Address	0x4804 FC78																															
Description	COMPLEXIO CONFIGURATION REGISTER for the complex I/O This register contains the lane configuration for the ULPS for each lane.																															
Type	RW																															
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16		LP_BUSY	HS_BUSY	15 14 13 12 11 10 9 8		7 6 5 4 3 2 1 0		RESERVED		RESERVED		RESERVED		RESERVED		LANE3_ULPS_SIG2		LANE2_ULPS_SIG2		LANE1_ULPS_SIG2		RESERVED		RESERVED		LANE3_ULPS_SIG1		LANE2_ULPS_SIG1		LANE1_ULPS_SIG1	
RESERVED																																

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
17	LP_BUSY	Indicates when there are still pending operations for VCs configured for LP mode. Forced to 1 when at least one VC is enabled and configured for LP mode. Read 0x0: LP logic is idle Read 0x1: LP logic is active	R	0x0
16	HS_BUSY	Indicates when there are still pending operations for VCs configured for HS mode. Forced to 1 when at least one VC is enabled and configured for HS mode Read 0x0: HS logic is idle Read 0x1: HS logic is active	R	0x0

Bits	Field Name	Description	Type	Reset
15:10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
9	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
8	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
7	LANE3_ULPS_ SIG2	Enables the ULPS for the lane #3. The HW should change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is change if lane #3 is a data lane. The state of the signal TxUlpsClk is change if lane #3 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective WRITE: Request to change to inactive state 0x1: READ: Active state effective WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0x0
6	LANE2_ULPS_ SIG2	Enables the ULPS for the lane #2. The HW should change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is change if lane #2 is a data lane. The state of the signal TxUlpsClk is change if lane #2 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective WRITE: Request to change to inactive state 0x1: READ: ACTIVE state effective WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0x0
5	LANE1_ULPS_ SIG2	Enables the ULPS for the lane #1. The HW should change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is change if lane #1 is a data lane. The state of the signal TxUlpsClk is change if lane #1 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective WRITE: Request to change to inactive state 0x1: READ: ACTIVE state effective WRITE: Change request to active. Address Offset	0x0000 008C	Physical Address	0x4804 FC8C	Instance	DSI_PROTOCOL_ENGINE
Description	VIDEO MODE TIMING REGISTER This register defines the video mode timing.				
Type	RW				

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0	BL_HS_INTERLEAVING	BL_LP_INTERLEAVING
---	--------------------	--------------------

Bits	Field Name	Description	Type	Reset
31:16	BL_HS_INTERLEAVING	Defines the number of TxByteClkHS clock cycles that can be used for interleaving high-speed command mode packet into Video Mode stream during blanking periods during VSA, VBP, VFP periods inside one video frame on PPI link. The supported values are from 0 to 65535.	RW	0x0000
15:0	BL_LP_INTERLEAVING	Defines the maximum number of bytes for Low Power command mode packets that can be sent on PPI link during blanking periods during VSA, VBP or VFP periods inside one video frame on PPI link. The supported values are from 0 to 65535	RW	0x0000

Table 7-418. DSI_VM_TIMING7

Address Offset	0x0000 0090	Instance	DSI_PROTOCOL_ENGINE		
Physical Address	0x4804 FC90				
Description	Defines the maximum number of bytes of Low Power command mode packets that can be sent on PPI link during blanking periods during VSA, VBP or VFP periods inside one video frame on PPI link. The supported values are from 0 to 65535				
Type	RW				

31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
ENTER_HS_MODE_LATENCY			
EXIT_HS_MODE_LATENCY			

Bits	Field Name	Description	Type	Reset
31:16	ENTER_HS_MODE_LATENCY	Defines the number of TxByteClkHS clock cycles necessary for entering to HS mode. It corresponds to the delay in number of HS clock cycles from assertion of TxRequestHS signal to 1 until assertion of TxReadyHS signal to 1. The supported values are from 0 to 65535 .	RW	0x0000
15:0	EXIT_HS_MODE_LATENCY	Defines the number of TxByteClkHS clock cycles necessary for exiting from HS mode. It corresponds to the maximum delay in number of TxByteClkHS from de-assertion of TxRequestHS signal until PPI link is in LP-11 state from which a new entrance to HS mode can be initiated which does not take more than ENTER_HS_MODE_LATENCY clock cycles. The supported values are from 0 to 65535	RW	0x0000

Display Subsystem Register Manual

www.ti.com

Bits	Field Name	Description	Type	Reset
20	RX_FIFO_NOT_EMPTY	FIFO status in command mode. Otherwise, this bit can be ignored. 0x0: The RX FIFO is empty (the FIFO does not contain any data for the VC) 0x1: The RX FIFO is not empty (the FIFO contains at least one byte for the VC)	R	0x0
19:17	DMA_TX_THRESHOLD	Defines the threshold value for the DMA request (associated to the TX FIFO) 0x0: 1x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits	RW	0x0
16	TX_FIFO_FULL	FIFO status in command mode. Otherwise, this bit can be ignored. 0x0: The TX FIFO is not full (the FIFO can accept at least one more 32-bit value) 0x1: The TX FIFO is full	R	0x0
15	VC_BUSY	Indicates if previously scheduled activities (packets, BTA) are still being processed. Forced to 1 by hardware if VC is enabled. Software should check this bit is 0 before changing channel configuration. 0x0: No pending operations for this VC 0x1: Pending operations for this VC	R	0x0
14	PP_BUSY	Line buffer busy status. 0x0: Software is permitted to write a new header for VP command mode traffic. 0x1: Software is NOT permitted to write a new header for VP command mode traffic.	R	0
13:10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
9	MODE_SPEED	Selection of the mode. This bit is ignored by hardware when video mode is selected. 0x0: Low-power mode (CMOS) is used to send short and long packets to the peripheral. 0x1: High speed mode (SLVS) is used to send short and long packets to the peripheral.	RW	0x0
8	ECC_TX_EN	Enables the ECC generation for the transmit header (short and long packets). 0x0: Disabled 0x1: Enabled	RW	0x0
7	CS_TX_EN	Enables the checksum generation for the transmit payload (long packet only). 0x0: Disabled. The value 0x00 is used. 0x1: Enabled. The Check-sum value is calculated by HW.	RW	0x0

Bits	Field Name	Description	Type	Reset
6	BTA_EN	<p>Send the bus turn around to the peripheral. It can be used when the automatic mode is enabled (BTA_SHORT_EN=1 or/and BTA_LONG_EN=1). In that case only one BTA is sent to the peripheral. The manual mode allows users to define for which packets, the turn around is required for example getting acknowledge from the peripheral.</p> <p>0x0: READS: BTA generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the BTA generation (not guarantee since it could already be on going, must not be used).</p> <p>0x1: READS: BTA generation has been requested by user (it could be on going but not completed). WRITES: Request for BTA generation.</p>	RW	0x0
5	TX_FIFO_NOT_EMPTY	<p>FIFO status</p> <p>0x0: The TX FIFO is empty (the FIFO does not contain any data for the VC)</p> <p>0x1: The TX FIFO is not empty (the FIFO contains at least one byte for the VC)</p>	R	0x0
4	MODE	<p>Selection of the mode</p> <p>0x0: Command mode.</p> <p>0x1: Video mode.</p>	RW	0x0
3	BTA_LONG_EN	<p>Enables the automatic bus turn-around after completion of each long packet transmission.</p> <p>0x0: Disabled</p> <p>0x1: Enabled</p>	RW	0x0
2	BTA_SHORT_EN	<p>Enables the automatic bus turn-around after completion of each short packet transmission.</p> <p>0x0: Disabled</p> <p>0x1: Enabled</p>	RW	0x0
1	SOURCE	<p>Selection of the source between L4 interconnect slave port and video port. This bit is ignored by hardware when video mode is selected.</p> <p>0x0: All the data are provided by the L4 interconnect slave port. Any transfer on the video port is ignored for this VC.</p> <p>0x1: If MODE=VIDEO_MODE, any data received on the video port (pixels and enabled synchronization events using DSI_CTRL[17] VP_HSYNC_START, DSI_CTRL[18] VP_HSYNC_END, DSI_CTRL[15] VP_VSYNC_START, DSI_CTRL[16] VP_VSYNC_END,) are sent on the VC (only one VC can be associated with the video port, the software must ensure that no more than one VC is enabled with the video port as the main source for data). If MODE=COMMAND_MODE, the VP_STALL signal is used by the protocol engine to indicate when new data are required. The synchronization signals are not generated by the display controller. Regardless of the MODE, no data can be provided on the L4 interconnect slave port.</p>	RW	0x0
0	VC_EN	<p>Enables the VC.</p> <p>0x0: Disabled. The VC must be disabled for any register change in the DSI_VCn_XXX registers the corresponding VC ID.</p> <p>0x1: Enabled. No change is allowed to the VC registers (except for setting the bit fields/registers: DSI_VCn_CTRL[6] BTA_EN, DSI_VCn_TE[15:0] TE_SIZE, DSI_VCn_TE[31] TE_START, DSI_VCn_LONG_XXX, DSI_VCn_SHORT_XXX, DSI_VCn_IRQXXX registers).</p>	RW	0x0

Table 7-424. DSI_VCn_TE

Address Offset	0x0000 0104+ (n* 0x20)	Index	n = 0 to 3
Physical Address	0x4804 FD04+ (n* 0x20)	Instance	DSI_PROTOCOL_ENGINE
Description	CONTROL REGISTER - Virtual channel This register controls the tearing effect logic. It defines the size of the transfer when TE occurs and enables the automatic TE mode.		
Type	RW		
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
TE_START TE_EN	RESERVED	TE_SIZE	

Bits	Field Name	Description	Type	Reset
31	TE_START	<p>Manual control of the start of the transfer. Users can use the TE interrupt to determine that the TE trigger has been received before setting the TE_START bit field. It is not mandatory to use the TE interrupt.</p> <p>0x0: Indicates the end of the transfer. The bit can be used to cancel the transfer if not already started. The FIFO must be flushed by software to ensure it contains no remaining data.</p> <p>0x1: Starts the transfer of the data. The size is defined in TE_SIZE. The bit field is set until the transfer completes. It is reset by hardware when the transfer completes.</p>	RW	0

Bits	Field Name	Description	Type	Reset
30	TE_EN	<p>Tearing effect control</p> <p>0x0: Disables the automatic transfer of the data using the TE trigger as a synchronization event. The interruption is used to know when the TE trigger is received. The hardware resets the bit field when the transfer completes(TE_SIZE=0).</p> <p>0x1: Enables the automatic transfer of the data using the TE trigger as a synchronization event.</p>	RW	0
29:24	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
23:0	TE_SIZE	Defines the number of bytes (payload data excluding the check-sum) to be sent. Users must perform the write into the DSI_VCn_LONG_PACKET_HEADER register before sending data from the DSI_VCn_LONG_PACKET_PAYLOAD register. The register value is decremented for every byte of the DSI link that is sent. At the end of the transfer (TE_SIZE = 0), the TE_EN bit field is reset by hardware. The DMA_request is asserted when the trigger is received in order to receive data in the TX FIFO. It must not be used until all data (TE_SIZE) have been received in the FIFO.	RW	0x000000

www.ti.com

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000000
8	PP_BUSY_CHANGE_IRQ	Video port ping-pong buffer busy status. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0
7	FIFO_TX_UDF_IRQ	FIFO underflow status. The FIFO used on the slave port for buffering the data received on the OCP slave port for the VC has underflowed which means that the data for the current packet have not been received in time since the transfer of the packet are already started (transfer started since the packet size is bigger than space allocated in the FIFO). 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
6	ECC_NO_CORRECTION_IRQ	ECC error status (short and long packets). No correction of the header because of more than 1-bit error. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
5	BTA_IRQ	Virtual channel - BTA status. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
4	FIFO_RX_OVF_IRQ	FIFO overflow error status. The FIFO used on the slave port for buffering the data received on the DSI link for the VC has overflowed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
3	FIFO_TX_OVF_IRQ	FIFO overflow error status. The FIFO used on the slave port for buffering the data received on the OCP slave port for the VC has overflowed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
2	PACKET_SENT_IRQ	Indicates that a packet has been sent. It is used when BTA manual mode is used. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
1	ECC_CORRECTION_IRQ	Virtual channel - ECC has been used to do the correction of the only 1-bit error status (short and long packet only). 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
0	CS_IRQ	Virtual channel - Check-Sum mismatch status. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

Table 7-434. DSI_VCn_IRQENABLE

Address Offset	0x0000 011C+ (n* 0x20)	Index	n = 0 to 3
Physical Address	0x4804 FD1C + (n* 0x20)	Instance	DSI_PROTOCOL_ENGINE
Description	INTERRUPT ENABLE REGISTER - Virtual channel This register regroups all the events related to VC.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED																									PP_BUSY_CHANGE_IRQ_EN	FIFO_TX_UDF_IRQ_EN	ECC_NO_CORRECTION_IRQ_EN	BTA_IRQ_EN	FIFO_RX_OVF_IRQ_EN	FIFO_TX_OVF_IRQ_EN	PACKET_SENT_IRQ_EN	ECC_CORRECTION_IRQ_EN	CS_IRQ_EN

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000000
8	PP_BUSY_CHANGE_IRQ_EN	Video port ping-pong buffer busy. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0

Bits	Field Name	Description	Type	Reset
7	FIFO_TX_UDF_IRQ_EN	FIFO underflow enable. The FIFO used on the slave port for buffering the data received on the OCP slave port for the VC has underflowed which means that the data for the current packet have not been received in time since the transfer of the packet are already started (transfer started since the packet size is bigger than space allocated in the FIFO). 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
6	ECC_NO_CORRECTION_IRQ_EN	ECC error (short and long packets). No correction of the header because of more than 1-bit error. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
5	BTA_IRQ_EN	Virtual channel -Bus turn around reception 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
4	FIFO_RX_OVF_IRQ_EN	FIFO overflow enable. The FIFO used on the slave port for buffering the data received on the DSI link for the VC has overflowed. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
3	FIFO_TX_OVF_IRQ_EN	FIFO overflow enable. The FIFO used on the slave port for buffering the data received on the OCP slave port for the VC has overflowed. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
2	PACKET_SENT_IRQ_EN	Indicates that a packet has been sent. It is used when BTA manual mode is used. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
1	ECC_CORRECTION_IRQ_EN	Virtual channel - ECC has been used to correct the only 1-bit error (short and long packet). 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
0	CS IRQ_EN	Virtual channel - Check-Sum of the payload mismatch detection 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0

Table 7-436. DSI_PHY_REGISTER0

Address Offset	0x0000 0000	Physical Address	0x4804 FE00	Instance	DSI_PHY
Description	Configuration register for HS mode timings				
Type	RW				
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0		
REG_THSPREPARE	REG_THSPRPR_THSZERO	REG_THSTRAIL	REG_THSEXIT		

Bits	Field Name	Description	Type	Reset
31:24	REG_THSPREPARE	REG_THSPREPARE timing parameter in multiples of DDR clock period. DDR clock = CLKIN4DDR/4. D-PHY specification: 40 ns + 4*UI ÷ 85 ns + 6*UI. UI = Unit Interval, equal to the duration of any HS state on the clock lane Default value is programmed for 400 MHz.	RW	0x1E
23:16	REG_THSPRPR_THSZERO	REG_THSPRPR_THSZERO timing parameter in multiples of DDR clock period. DDR clock = CLKIN4DDR/4. D-PHY specification: 145 ns + 10*UI Default value is programmed for 400 MHz.	RW	0x48
15:8	REG_THSTRAIL	REG_THSTRAIL timing parameter in multiples of DDR clock period. DDR clock = CLKIN4DDR/4. D-PHY specification: 60 ns + 4*UI Default value is programmed for 400 MHz.	RW	0x1D
7:0	REG_THSEXIT	REG_THSEXIT timing parameter in multiples of DDR clock period. DDR clock = CLKIN4DDR/4) D-PHY specification: 100 ns Default value is programmed for 400 MHz.	RW	0x3A

			0x6: 9 cycles																												
			0x7: 10 cycles																												
			Default value: 5 cycles																												
23:21	RESERVED		Reserved.														R				0x0										
20:16	REG_TLPXBY2		(TLPX)/2 timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN4DDR/4. Default value is programmed for 400 MHz This is the internal timer value. The value seen on line will have variance due to rise/fall mismatch effects. Note: TLPX is used to define the length of LP-01 state in HS Start of Transmission sequences on clock and data lanes. For all other purposes TLPX is defined by the period of TxLPEsc clock.														RW				0x0A										
15:8	REG_TCLKTRAIL		REG_TCLKTRAIL timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN4DDR/4.														RW				0x1A										

Bits	Field Name	Description	Type	Reset
		D-PHY specification: 60 ns Default value is programmed for 400 MHz.		
7:0	REG_TCLKZERO	REG_TCLKZERO timing parameter in multiples of DDR clock period. DDR clock = CLKIN4DDR/4. D-PHY specification: (REG_TCLKPREPARE + REG_TCLKZERO) 300 ns Derived specification for REG_TCLKZERO (Min REG_TCLKPREPARE = 38 ns): REG_TCLKZERO 262 ns Default value is programmed for 400 MHz.	RW	0x6A

2D/3D Graphics Accelerator

This chapter describes the 2D/3D graphics accelerator (SGX) for the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

NOTE: The SGX subsystem is a Texas Instruments instantiation of the POWERVR® SGX530 core from Imagination Technologies Ltd.

This document contains materials that are ©2003-2007 Imagination Technologies Ltd.

POWERVR® and USSE™ are trademarks or registered trademarks of Imagination Technologies Ltd.

8.2 SGX Integration	1973
8.3 SGX Functional Description	1975
8.4 SGX Register Manual	1977

8.1 SGX Overview

The 2D/3D graphics accelerator (SGX) subsystem accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics applications. The SGX subsystem is based on the POWERVR® SGX core from Imagination Technologies. SGX is a new generation of programmable POWERVR graphic cores. The POWERVR SGX530 v1.2.5 architecture is scalable and can target all market segments from mainstream mobile devices to high-end desktop graphics. Targeted applications include feature phone, PDA, and hand-held games.

[Figure 8-1](#) shows the SGX subsystem in the device.

Figure 8-1. Graphics Accelerator Highlight

sgx-001

The SGX graphics accelerator can simultaneously process various multimedia data types:

- Pixel data
- Vertex data
- Video data
- General-purpose processing

This is achieved through a multithreaded architecture using two levels of scheduling and data partitioning enabling zero-overhead task switching.

The SGX subsystem is connected to the L3 interconnect by a 128-bit master and a 32-bit slave interface.

8.1.1 POWERVR SGX Main Features

- 2D graphics, 3D graphics, vector graphics, and programming support for GP-GPU functions
- Tile-based architecture
- Universal scalable shader engine (USSE™) – multithreaded engine incorporating pixel and vertex shader functionality
- Advanced shader feature set – in excess of Microsoft VS3.0, PS3.0, and OpenGL2.0

- Industry-standard API support – Direct3D Mobile, OpenGL ES 1.1 and 2.0, OpenVG v1.0.1
- Fine-grained task switching, load balancing, and power management
- Advanced geometry direct memory access (DMA) driven operation for minimum CPU interaction
- Programmable high-quality image anti-aliasing
- POWERVR SGX core MMU for address translation from the core virtual address to the external physical address (up to 4GB address range)
- Fully virtualized memory addressing for OS operation in a unified memory architecture
- Advanced and standard 2D operations [e.g., vector graphics, BLTs (block level transfers), ROPs (raster operations)]
- 32K stride support

8.1.2 SGX 3D Features

- Deferred pixel shading
- On-chip tile floating point depth buffer
- 8-bit stencil with on-chip tile stencil buffer
- 8 parallel depth/stencil tests per clock
- Scissor test
- Texture support:
 - Cube map
 - Projected textures
 - 2D textures
 - Nonsquare textures
- Texture formats:
 - RGBA 8888, 565, 1555
 - Monochromatic 8, 16, 16f, 32f, 32int
 - Dual channel, 8:8, 16:16, 16f:16f
 - Compressed textures PVR-TC1, PVR-TC2, ETC1
 - Programmable support for all YUV formats
- Resolution support:
 - Frame buffer maximum size = 2048 x 2048
 - Texture maximum size = 2048 x 2048
- Texture filtering:
 - Bilinear, trilinear
 - Independent minimum and maximum control
- Antialiasing:
 - 4x multisampling
 - Up to 16x full scene anti-aliasing
 - Programmable sample positions
- Indexed primitive list support
 - Bus mastered
- Programmable vertex DMA
- Render to texture:
 - Including twiddled formats
 - Auto MipMap generation
- Multiple on-chip render targets (MRT).

Note: Performance is limited when the on-chip memory is not available.

8.1.3 Universal Scalable Shader Engine (USSE) – Key Features

The USSE is the engine core of the POWERVR SGX architecture and supports a broad range of instructions.

- Single programming model:
 - Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
 - Zero-cost swapping in, and out, of threads
 - Cached program execution model
 - Dedicated pixel processing instructions
 - Dedicated video encode/decode instructions
- SIMD execution unit supporting operations in:
 - 32-bit IEEE float
 - 2-way 16-bit fixed point
 - 4-way 8-bit integer
 - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
 - Subroutine calls
 - Loops
 - Conditional branches
 - Zero-cost instruction predication
- Procedural geometry:
 - Allows generation of primitives
 - Effective geometry compression
 - High-order surface support
- External data access:
 - Permits reads from main memory using cache
 - Permits writes to main memory
 - Data fence facility
 - Dependent texture reads

8.2 SGX Integration

Figure 8-2 highlights the SGX subsystem integration in the device.

Figure 8-2. SGX Subsystem Integration

sgx-002

8.2.1 Clocking, Reset, and Power-Management Scheme

8.2.1.1 Clocks

The SGX subsystem operates from two clocks: an interface clock (SGX_ICLK) and a functional clock (SGX_FCLK). The power, reset, and clock management (PRCM) module generates and distributes both clocks inside the device. The SGX clock tree is depicted in the *SGX Power Domain Clocking Scheme* figure in [Chapter 3, Power, Reset, and Clock Management](#).

Table 8-1. Clock Descriptions

Signal Name	I/O ⁽¹⁾	Description
SGX_FCLK	I	Functional clock (two possible clock sources) → Functional clock domain
SGX_ICLK	I	Interface clock (L3 interconnect clock domain) → Interface clock domain

⁽¹⁾ I =Input; O=Output

- The SGX_ICLK interface clock manages the data transfer on the L3 master and slave ports. The source of SGX_ICLK is the PRCM clock (SGX_ICLK), which belongs to the SGX clock domain and runs at the L3 interconnect clock speed. The SGX_ICLK frequency is selected based on the whole device L3 interconnect clock frequency. For more information on the interface clock, see [Chapter 3, Power, Reset, and Clock Management](#).

When no longer required by the SGX subsystem, SGX_ICLK can be disabled by software at the PRCM level by setting the PRCM.CM_ICLKEN_SGX[0] EN_SGX bit to 0. For more information, see

the SGX Power Domain Clock Controls section in [Chapter 3, Power, Reset, and Clock Management](#).

NOTE: SGX_ICLK is cut only if the SGX is ready to go into idle state. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

- SGX_FCLK is the functional clock and is used inside the SGX subsystem to generate SGX 2D and 3D domain clock signals.

The source of SGX_FCLK is shown in the SGX Power Domain Clock Controls section of the [Chapter 3, Power, Reset, and Clock Management](#) chapter. Selection is made at the PRCM level by setting the PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX bit field (see the *GFX Functional Clock Ratio Settings* table in [Chapter 3, Power, Reset, and Clock Management](#)).

Depending on the clock source selection and DPLL settings, SGX_FCLK can support a frequency up to 200 MHz.

SGX_FCLK gating depends on the PRCM.CM_FCLKEN_SGX[1] EN_SGX bit. Clearing this bit to 0 indicates that both SGX clocks are no longer needed and can be cut at the PRCM level if the module is ready to enter the idle state. For more information, see the SGX Power Domain section in [Chapter 3, Power, Reset, and Clock Management](#).

8.2.1.2 Resets

The SGX subsystem has its own reset domain. Global reset of the SGX is performed by activating the SGX_RST signal in the SGX_RST domain. Software controls the release of SGX_RST using the PRCM.RM_RSTCTRL_SGX[0] SGX_RST bit.

8.2.1.3 Power Management

The SGX subsystem has its own power domain (SGX power domain). See [Chapter 3, Power, Reset, and Clock Management](#), for additional information about the SGX power domain.

As described in [Section 8.2, SGX Integration](#), the SGX subsystem receives two clock signals from the PRCM module. The functional clock is used inside the SGX to generate clock signals to the multiple internal module SGX clock domains. The division ratio depends on the PRCM registers setting. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

Three power-management modes are defined:

- Deep power sleep (All clocks are gated.)
- Idle (2D and 3D clocks are gated.)
- 3D (No clock is gated.)

The SGX handles the automatic clock gating performed on the multiple internal module clock domains.

8.2.2 Hardware Requests

8.2.2.1 Interrupt Request

The SGX subsystem can generate one interrupt (SGX_IRQ) to the MPU subsystem interrupt controller mapped on M_IRQ_21.

8.3 SGX Functional Description

8.3.1 SGX Block Diagram

The SGX subsystem is based on the POWERVR® SGX530 core from Imagination Technologies. The architecture uses programmable and hard coded pipelines to perform various processing tasks required in 2D, 3D, and video processing. The SGX architecture comprises the following elements:

- Coarse grain scheduler
 - Programmable data sequencer (PDS)
 - Data master selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 8-3 shows a block diagram of the SGX cores.

Figure 8-3. SGX Block Diagram

8.3.2 SGX Elements Description

The coarse grain scheduler (CGS) is the main system controller for the POWERVR SGX architecture. It consists of two stages, the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

There are three data masters in the SGX core:

- The VDM is the initiator of transform and lighting processing within the system. The VDM reads an input control stream, which contains triangle index data and state data. The state data indicates the PDS program, size of the vertices, and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together according to the configuration provided by the driver and presented to the DMS.
- The PDM is the initiator of rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile, which allows for optimum efficiency within each pipe due to locality of data. It determines the amount of resource required within the USSE for each task. It merges this with the state address and issues a request to the DMS for execution on the USSE.
- The general-purpose data master responds to events within the system (such as end of a pass of triangles from the ISP, end of a tile from the ISP, end of render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or synchronized execution of a program on the PDS. The program may, or may not cause a subsequent task to be executed on the USSE.

The USSE is a user-programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbiter/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache, as well as providing Level 0 caching for texture and USSE requests. The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration, as well as any required texture decompression, are performed between the three data streams.

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from either the iterators or USSE modules and translates these into requests in the multilevel cache. Data returned from the cache are then formatted according to the texture format selected, and sent to the USSE for pixel-shading operations.

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing the memory storage requirements and the amount of pixel processing to be performed.

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address into the output buffer and then USSE returns the relevant pixel data. The address order is determined by the frame buffer mode. The pixel coprocessor contains a dithering and packing function.

8.4 SGX Register Manual

CAUTION

All SGX registers are limited to 32-bit data accesses, 8- and 16-bit accesses are not allowed because they can corrupt register content.

Table 8-41. Register Call Summary for Register OCP_DEBUG_STATUS

Interconnect

This chapter describes the Interconnect.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

NOTE:

- The L3 interconnect is an instantiation of the **SonicsMX®** interconnect from Sonics, Inc.
- The L4 interconnects are instantiations of the **Sonics3220** interconnect from Sonics, Inc.

This document contains materials that are ©2003-2009 Sonics, Inc., and that constitute proprietary information of Sonics, Inc.

SonicsMX and Sonics3220, are trademarks or registered trademarks of Sonics, Inc. All such materials and trademarks are used under license from Sonics, Inc. For additional information, see the SonicsMX or Sonics3220 Reference manuals, or contact Sonics, Inc.

SMX is an abbreviation for SonicsMX.

NOTE: This chapter gives information about all modules and features in the high-tier device. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

Topic	Page
9.1 Interconnect Overview	1994
9.2 L3 Interconnect	2003
9.3 L4 Interconnects	2059

9.1 Interconnect Overview

9.1.1 Terminology

The following terminology is critical to understanding the interconnect:

- Initiator: Module able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).
- Target: Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

NOTE: A module can have several separate ports; therefore, a module can be both an initiator and a target.

- Agent: Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).
- OCP: Open-core protocol (www.ocpip.org) is point-to-point standard protocol between one master port and one slave port.
- OCP master port: Port that can generate OCP commands. An initiator includes at least one master port.
- OCP slave port: Port that responds to OCP commands. A target includes one slave port.
- Interconnect: The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it.
- Register target (RT): Special TA used to access the interconnect internal configuration registers
- Dataflow signal: Any OCP signal that is part of a clearly identified OCP transfer or dataflow (typically: command, address, byte enables, etc.). The signal behavior is defined by the OCP protocol semantics.
- Sideband signal: Any OCP signal whose behavior is not associated to a precise OCP transaction or dataflow. The OCP standard does not define specific semantics for these signals.
- Out-of-band error: Any OCP signal whose behavior is associated to an error-reporting scheme of the device, as opposed to in-band errors.

NOTE: Interrupt requests and DMA requests are not routed by the interconnect in the device.

- Firewall: A programmable feature integrated in a target agent or L4 interconnect to prevent unauthorized access to or from a module. A firewall can be configured using three criteria:
 - Initiator requesting access
 - Address space access
 - Type of access
- Thread: Logical entities that allow to have separate independent data flows on a single port.
- Multithreaded ports: A physical port able to simultaneously handle several outstanding transactions. On a multithreaded port, one physical channel (port) is used concurrently for several logical channels (threads). The transfer in each thread must remain in order with respect to each other, but the order between threads can change between requests and responses. Thread management is used for performance optimization purposes and is automatically handled by the system.
- ConnID: Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted inband with the request and is used for firewall and error-logging mechanism.
- Firewall comparison mechanism: A comparison made in the firewall between access in-band qualifiers and access permissions that are programmed in the firewall configuration registers. If the comparison is successful, access is allowed; otherwise, access is denied.
- MCmd qualifier: Command bus that indicates the type of transfer requested. [Table 9-1](#) lists the commands encoded.

Table 9-1. MCmd Qualifier Description

MCmd[2:0]	Transaction Type
0 0 0	Idle
0 0 1	Write
0 1 0	Read
0 1 1	ReadEx
1 0 0	Not used
1 0 1	Write nonposted
1 1 0	Not used
1 1 1	Not used

- MReqInfo qualifier: Four MReqInfo qualifiers describe the access during the use of the firewall comparison mechanism, as described in [Table 9-2](#).

Table 9-2. MReqInfo Qualifier Description

Qualifiers	Description
MReqType	0: Data access
	1: Opcode fetch
MReqSupervisor	0: User mode
	1: Supervisor mode
MReqDebug	0: Functional access
	1: Debug access

- [L3_PM_REQ_INFO_PERMISSION_i](#): Register that configures the combination of the MReqInfo, allowing access permission to the TM based on the MReqInfo in-band qualifier values.
- SError: Target that indicates an error condition to the initiator.
- SResp qualifier: Response from the target to the initiator concerning the transaction.

Table 9-3. SResp Qualifier Description

SResp[1:0]	Description
0 0	No response
0 1	Data valid/accept
1 0	Not used
1 1	Error

9.1.2 Architecture Overview

The device memory hierarchy includes four levels:

- L1 is internal to the CPUs. It concerns data exchange with the internal Level1 cache memory subsystem, and it is the closest memory to the microprocessor unit (MPU) core and the IVA2.2 core.
- L2 is included in the IVA2.2 subsystem and the MPU subsystem.
- The chip-level interconnect consists of one L3 interconnect and four L4 interconnects. It enables communication among the modules and subsystems in the device.

[Figure 9-1](#) shows an overview of the L3 and L4 interconnect architecture.

- L3 handles many types of data transfers, especially exchanges with system-on-chip/external memories. L3 transfers data with a maximum width of 64 bits from the initiator to the target. The L3 interconnect is a little-endian platform
- L4 is composed of the L4-Core, L4-Per, L4-Wakeup, and L4-Emu interconnects and handles data transfers to peripherals. It supports 32-bit data width transfer and is optimized to support the interconnection of many peripheral targets. These backplanes assume little-endian transactions for narrower targets (8-bit, 16-bit) when doing data packing and unpacking.

Figure 9-1. Interconnect Architecture Overview

Modules are connected to the interconnect through an IA for the initiator module and a TA for target modules. Each module/subsystem connection is statically configured to tune the access depending on the characteristics of the module.

To unauthorized a module or L4 interconnect access, some TAs include configurable firewalls (FWs). A firewall restricts or filters the accesses allowed to an initiator according to different access criteria. The firewalls can usually be configured by software.

The L3 and L4 interconnect default setting is fully functional; it enables all possible functional data paths and a minimal default protection setting. However, it is possible to modify the interconnect parameters to fit user expectations.

9.1.3 Module Distribution

IAs and TAs provide the interface to connect the different modules and the interconnect.

[Table 9-4](#) through [Table 9-13](#) list the device modules, subsystems, and associated agents. The agents are listed for each interconnect domain:

- L3 initiator and target agents
- L4-Core initiator and target agents
- L4-Per initiator and target agents
- L4-Emu initiator and target agents
- L4-Wakeup initiator and target agents

9.1.3.1 L3 Interconnect Agents

[Table 9-4](#) and [Table 9-5](#) list the IAs and TAs, respectively, of the L3 interconnect.

Table 9-4. L3 Initiator Agents

Module Name	Description
MPU SS	MPU subsystem port
Display SS	Display subsystem port
IVA2.2 SS	IVA2.2 subsystem port
SGX SS	Graphics subsystem port
CAMERA SS	Camera subsystem port
SAD2D	Die-to-die port
sDMA read	System DMA read port
sDMA write	System DMA write port
High-Speed (HS) USB OTG	Universal Serial Bus High-Speed port OTG controller
High-Speed (HS) USB Host	Universal serial bus High-Speed port host controller
DAP	Debug access port (JTAG/Emulation access to system resources)

Table 9-5. L3 Target Agents

Module Name	Description
SMS	SDRAM memory scheduler port
GPMC	General-purpose memory controller (for flash memory, SRAM, SROM, etc.) port
OCM-ROM	On-chip memory ROM port
OCM-RAM	On-chip memory RAM port
SGX	Graphics subsystem port
IVA2.2	Image video and audio accelerator subsystem port
RT	Register target port to configure L3
L4-Core	Port for L4-Core interconnect
L4-Peripherals	Port for L4-Per interconnect

Table 9-5. L3 Target Agents (continued)

Module Name	Description
L4-Emu	Port for L4-Emu interconnect

For more details on the register target module, see [Section 9.2.3.2, Register Target](#).

9.1.3.2 L4-Core Agents

Table 9-6. L4-Core Initiator Agent

Module Name	Description
L3 interconnect	L3 interconnect port

NOTE: A unique L3 port is used for communication with the L4-Core. For the list of initiators allowed to access the L4 Core peripherals, see [Table 9-14](#).

Table 9-7. L4-Core Target Agents

Module Name	Description
Display subsystem	Display subsystem configuration port
Camera subsystem	Camera subsystem port

9.1.4 Connectivity Matrix

[Table 9-14](#) lists the functional paths between the L3 interconnect initiator modules and the L3 and L4 TAs. The functional paths are indicated by the use of the following:

- Cell contains a + sign when a functional path exists.
- Cell is blank when no functional path exists.

Table 9-14. Connectivity Matrix

Initiator Ports	L4-Core Target ⁽¹⁾	L4-Per Target ⁽¹⁾	L4-Emu Target ⁽¹⁾	L4-Wakeu p Target ⁽¹⁾	SMS Target	GPMC Target	OCM RAM Target	OCM ROM Target	RT Target	IVA2.2 Target	SGX Target	MAD2D
MPU IA	+	+	+	+	+	+	+	+	+	+	+	+
SGX IA					+	+	+					+
IVA2.2 IA	+	+	+	+	+	+	+		+	+		+
DSS IA					+		+					+
CAM IA					+		+					+
HS USB Host IA					+	+	+					+
HS USB OTG IA					+	+	+					+
sDMA RD IA	+	+	+	+	+	+	+			+	+	+
sDMA WR IA	+	+	+	+	+	+	+			+	+	+

⁽¹⁾ A functional data path always exists from L4 IAs (Core, Per, Emu, and Wakeup) to any L4 target module (Core, Per, Emu, and Wakeup). As a consequence, all L3 initiator modules for which a data path exists to an L4 TA can access L4 peripherals. Restrictions on peripheral access depend on L4 protection mechanism. For more details, see [Section 9.3.3.3](#).

9.2 L3 Interconnect

This section describes the L3 interconnect and its components. With the exception of register points, each component includes functionality for both the request and response network.

9.2.1 Overview

The L3 interconnect links cores in a flexible topology that couples low power with high performance. Innovative physical structures and advanced protocols ensure bandwidth and latency to individual IP cores, providing dedicated connections between IP cores and logical connections over a shared interconnect.

[Figure 9-2](#) shows the L3 interconnect.

Figure 9-2. L3 Interconnect Overview

The following are the main features of the L3 interconnect:

- 64-bit multipath interconnect to eliminate on-chip bottlenecks
- Special internal target for access to L3 registers (RT)
- Guaranteed quality of service for real-time hardware operators, while maintaining optimal memory latency for MPU accesses to memory resources
- True little-endian platform
- Transaction error tracking and logging
- Built-in protection features:
 - Allow access only to authorized initiator
 - Distributed region-based firewalls for system resource sharing and protection management
- Signaling support for chip-level power management infrastructure
- Two interrupt line signaling transaction error

9.2.2 L3 Interconnect Integration

9.2.2.1 Clocking, Reset, and Power-Management Scheme

9.2.2.1.1 Clocks

The power, reset, and clock management (PRCM) module provides the L3_ICLK as the main clock to the L3 interconnect.

In addition to L3_ICLK, two additional sample signals are provided to module agents to allow internal synchronization. The modules are as follows:

- L4-Core
- L4-Per

For more details on the L3 clock and its setting, see [Chapter 3, Power, Reset, and Clock Management](#).

Table 9-15. L3 Interconnect Clocks

Type	Name	Source	Description
Interface/functional	L3_ICLK	PRCM	Main clock for L3 interconnect

9.2.2.1.2 Resets

The L3 interconnect receives a single reset signal, CORE_RST, from the PRCM module. CORE_RST is the reset signal to the core power domain. (For more details see [Power, Reset, and Clock Management](#).) When asserted, CORE_RST resets the L3 internal registers. There is no software reset for the L3 interconnect.

Table 9-16. L3 Interconnect Reset

Type	Reset Domain	Source	Description
Hardware	CORE_RST	PRCM	Asynchronous reset for the entire interconnect

9.2.2.1.3 Power Domain

The L3 interconnect connects into the CORE power domain, which can dynamically switch between supported OPPs. For more details on power voltage scaling, see [Power, Reset, and Clock Management](#).

Table 9-17. L3 Interconnect Power Domain

Interconnect	Power Domain
L3 interconnect	CORE

9.2.2.1.4 Power Management

As part of the system-wide power-management scheme, the L3 interconnect enters an idle state at the request of the PRCM module. (For more details, see [Chapter 3, Power, Reset, and Clock Management](#).) The L3 interconnect is always in smart-idle mode; that is, it goes into idle state after receiving the request from the PRCM module once all transfer requests are serviced. This functionality is handled by hardware. The L3 interconnect sends an acknowledge signal back to the PRCM module when it enters the idle state.

9.2.2.2 Hardware Requests

9.2.2.2.1 Interrupt Requests

Three interrupt lines are present at the boundary of the L3 interconnect (see [Table 9-18](#)). They are used for hardware error management.

Table 9-18. L3 Interconnect Hardware Requests

Type	Name	Destination	Description
Interrupt	M_IRQ_9	MPU interrupt controller for debug errors	L3 interconnect provides a mechanism to group core-detected and internal interconnect errors. See Section 9.3.3.4, Error Handling .
Interrupt	M_IRQ_10	MPU interrupt controller for application errors	
Interrupt	IVA2_IRQ[39]	IVA2.2 interrupt controller for application errors	

9.2.3 L3 Interconnect Functional Description

9.2.3.1 Initiator Identification

An InitiatorID is assigned to every thread on every initiator socket. The ID uniquely identifies the initiator and thread for an interconnect transfer see [Table 9-19](#). The interconnect uses InitiatorIDs for a number of purposes, including the following:

- Initiator source identification for the protection mechanism (see [Section 9.2.3.3, L3 Protection and Firewalls](#))
- Response route generation (performed internally to the TAs)
- Firewall error logging
- L3 interconnect error logging

Table 9-19. InitiatorID Definition

Initiator	InitiatorID
HS USB Host	0
HS USB OTG	2
sDMA rd	3 , 4 , 5, 6
sDMA wr	7, 8
DAP	9
CAM	10, 11, 12
SGX	13
IVA2.2 SS DMA	14, 15, 16, 17, 18, 19
IVA2.2 SS	20, 21, 22
MPU SS	23, 24, 25, 26, 27
SAD2D	28
DSS	29

9.2.3.2 Register Target

An RT is a specialized TA used to access L3 interconnect internal configuration registers.

RT configuration options are a subset of those available for TAs. For more details, see [Section 9.2.5.3](#).

9.2.3.3 L3 Protection and Firewalls

Protection in the device relies heavily on L3 firewalls and their configuration. Nine targets are protected through the use of firewalls. The number of protected regions varies on the target, with a maximum of eight regions. [Table 9-20](#) lists the protection type and the number of protected regions for each target.

Table 9-20. Target Firewall and Region Configuration

Target	Firewall	Number of Regions
SMS	Included in the SMS module	See <i>Memory Subsystem</i> .
GPMC	Yes	8
OCM-RAM	Yes	8
OCM-ROM	Yes	3
MAD2D	Yes	8
SGX Target	No	0
IVA2.2 target	Yes	4
L4-Core	Included in the L4 module	See Section 9.3, L4 Interconnects .
L4-Wakeup	Included in the L4 module	See Section 9.3, L4 Interconnects .
L4-Emu	Included in the L4 module	See Section 9.3, L4 Interconnects .
RT	Yes	2

The protection mechanism designates protection regions within the address space of certain targets. Access to these regions is granted only for certain initiators, based on transaction attributes (transmitted through MReqInfo). Each protection region is characterized with several configurable attributes (base address, size, specific access rights, and priority setting).

The protection mechanism uses the following attributes of a request:

- The address field and the address space field are used to determine which region has been hit. The region ID selects one table entry of the firewall look-up table.
- The region ID points to a unique set of permission registers: Read_Permission, Write_Permission, ReqInfo_Permission.
- The Initiator ID is used to determine the permission of the initiator (read/write permission) with respect to the concerned region.
- The access types (read or write) and the transaction attributes (MReqInfo in-band qualifiers) are used to grant or reject the access.

The first check determines whether the type of incoming request (read or write) is allowed, according to the Initiator MCConnID and its read and write permissions. The second check determines whether the MReqInfo bits of the incoming request are within the allowed pattern established by the MReqInfo permission bits. If both check results are positive, the request is allowed to access the target. Otherwise, the access is denied, the request is not forwarded to the target, an out-of-band error indication is reported, and an in-band error response is returned to the initiator (except for writes that were posted at the IA). [Figure 9-3](#) shows the flow used to identify and accept a new request.

Figure 9-3. Flow Chart of the Protection Mechanism

intc-014

To summarize, firewalls accept or reject a request depending on the following:

- Initiator originating the request
 - Command (read or write) requested
 - MReqInfo bus state
 - Region access in the target memory space

Software must configure the L3 firewalls properly to allow the right initiators, with the right MReqInfo access, on the well-defined size region. All the registers relative to the L3 firewalls are grouped in the protection mechanism (PM) register block.

NOTE: The PM qualifies the protection mechanism register associated with a firewall target. The targets protected by a firewall are listed in [Table 9-20](#). These PM registers do not exist if no firewall is associated with the target.

9.2.3.3.1 Protection Region

Two types of regions are distinguished in a target firewall (see Figure 9-4):

- Default region: Available in all targets; spans the entire target address range
 - Normal region: Number varies in a target; they have identical capabilities

Each region has the following characteristics:

- A base address, relative to the target address itself, and an address space

- A size
- Specific access rights, as defined through the MReqInfo qualifiers
- A priority level, from 0 (lowest) to 3 (highest)

Figure 9-4. L3 Firewall Implementation

9.2.3.3.1.1 Default Region/Region0

Region 0 is the default region of a whole target; it spans the entire target address space.

The default region is always the lowest priority. This region is systematically overlapped when other regions are set.

The [L3_PM_ADDR_MATCH_k](#) register is not accessible. Its configuration corresponds to all the possible addresses for the target, including all of ADDR_SPACE. It is not possible to program multiple ADDR_SPACE addresses in a normal region.

9.2.3.3.1.2 Normal Regions

Normal regions have identical features.

A given request either maps into a specific protection region or is considered to have hit the default protection region if no normal region is hit.

The protection regions can only be configured for a memory space that is power-of-two in size and size-aligned using the SIZE bit field [L3_PM_ADDR_MATCH_k](#) [7:3] (as listed in [Table 9-21](#)). When the SIZE bit field [L3_PM_ADDR_MATCH_k](#) [7:3] is set to 0, the region is disabled.

NOTE: k denotes the region number. Depending on the target, n varies from 0 to 7.

[Table 9-21](#) lists the size encoding for each value set in the SIZE bit field.

Table 9-21. L3 Firewall Size Parameter Definition

Possible Configuration		
Size ⁽¹⁾	Region Size	Base_Addr ⁽²⁾
0x0	Region disabled	Any (nonsignificant)
0x1	1K-byte	0x0000000
		0x0000400
		0x0000800
		...
0x2	2K-byte	0x0000000
		0x0000800
		0x0001000
		...
...
0x17	$2^{(17-1)}K$ -byte	
Others	Not allowed	-

⁽¹⁾ When the size parameter is set to 0, the region is disabled.

⁽²⁾ The base address depends on user settings.

9.2.3.3.2 Priority Level Overview

Each L3 firewall region is prioritized. Depending on its priority level, a region can override the settings of another region.

- Region 0 is the only allowed priority 0 region (lowest priority).
- Region 1 is the only allowed priority 3 region (highest priority).
- Others regions are defined as priority 1 or 2.

CAUTION

LEVEL bitfield value of ADDR_MATCH_1 register (Region 1 firewall configuration) must be kept to his default reset value and must not be changed; otherwise, the result will be unpredictable and can create unexpected protection holes or denial of service.

Protection level is defined by the LEVEL bit [L3_PM_ADDR_MATCH_k](#), where n is greater than 2. [Figure 9-5](#) represents the priority level with associated regions.

When an address hits two or more regions with different priority levels, the highest priority region protections are applied. The overlay region can overlap all or a part of a nonoverlap region.

CAUTION

Configuring two overlapping protection regions with the same priority level leads to undefined behavior.

Hardware behavior in the case of overlapping protection regions is undefined. A region with higher priority must be used to mask a region that is being reprogrammed, and any protection holes must be avoided during this reconfiguration.

To change the protection settings of a region, follow this procedure:

1. Ensure that a free region is available to be used as a high-priority region.

2. Program this region as a high-priority region so its parameters match the region to be changed. The final programming must be the [L3_PM_ADDR_MATCH_K](#) register, which includes the priority attribute and the size parameter to enable the region.
3. Disable the region to be configured or reconfigure it by setting the SIZE bit field to 0.
4. Set up all region control registers with the new configuration. The final programming must be the [L3_PM_ADDR_MATCH_K](#) register, which includes the size parameter to enable the region.
5. Disable the high-priority region by setting its size to 0.

This procedure must be used each time there is an overlap between the originally defined region and the newly defined region. The use of a high-priority region is required to keep protection active during programming.

Figure 9-5. L3 Region Overlay and Priority Level Overview

intc-001

9.2.3.3.3 Read and Write Permission

Read permission and write permission are configured using two registers:

- [L3_PM_READ_PERMISSION_i](#)
- [L3_PM_WRITE_PERMISSION_i](#)

The [L3_PM_READ_PERMISSION_i](#) and [L3_PM_WRITE_PERMISSION_i](#) registers allow the setting of read and write permission to one or more initiators. To grant read or write access, set the bit associated with the initiator to 1.

9.2.3.3.4 REQ_INFO_PERMISSION Configuration

The firewall comparison mechanism enables access to a protected target only when a correct combination of four MReqInfo in-band parameters is transmitted.

MReqInfo is a combination of a fixed 3-bit pattern that corresponds to a combination of the parameters MReqDebug, MReqType, and MReqSupervisor.

Different valid MReqInfo combinations can be defined for each L3 firewall region based on the [L3_PM_REQ_INFO_PERMISSION_i](#) value, which is programmed by software.

For each region, [L3_PM_REQ_INFO_PERMISSION_i](#) lists the possible MReqInfo combinations. Setting a Reqbit in this register determines the type of access authorized to the initiator.

[Table 9-22](#) lists the MReqInfo combinations available and the Reqbit associated with it.

Table 9-22. MReqInfo Parameter Combinations

Reqbit	MReqInfo		
	MReqSupervisor	MReqDebug	MReqType
0	User	Functional	Data
1	User	Functional	Code
2	User	Debug	Data
3	User	Debug	Code
4		Reserved for non-GP devices	
5		Reserved for non-GP devices	
6		Reserved for non-GP devices	
7		Reserved for non-GP devices	
8	Supervisor	Functional	Data
9	Supervisor	Functional	Code
10	Supervisor	Debug	Data
11	Supervisor	Debug	Code
12		Reserved for non-GP devices	
13		Reserved for non-GP devices	
14		Reserved for non-GP devices	
15		Reserved for non-GP devices	

[Figure 9-6](#) shows an example of the [L3_PM_REQ_INFO_PERMISSION_i](#) setting. In this example, [L3_PM_REQ_INFO_PERMISSION_i](#) is set to 0x0C05 (16'b0000_1100_0001_0101) for a specific region, which will grant access only if the request:

- User + Functional + Data
- User + Debug + Data
- Supervisor + Debug + Data
- Supervisor + Debug + Code

Figure 9-6. Example of REQ_INFO_PERMISSION Register

As another example, to configure a target accessible only for data and in a user mode, Reqbit 0, 1, 2 and 3 must be set. Therefore, the [L3_PM_REQ_INFO_PERMISSION_i](#) register must be set to 0x000F.

9.2.3.3.5 L3 Firewall Registers Overview

[Table 9-23](#) lists the L3 firewall permission-setting registers. [L3_PM_ADDR_MATCH_k](#), which is shown in this table, is not an accessible register.

Table 9-23. L3 Firewall Permission-Setting Registers

Register Name	Register Field Name	Field Modifiability	Parameter Comments	Region Comments
Region 0				
L3_PM_ADDR_MATCH_k (k=0)	ADDR_SPACE[2:0]	Hard coded	Corresponds to all the target memory space	This region is the default region. The default setting can be changed only with correct access according to L3 RT register.
	SIZE[7:3]	Hard coded	Corresponds to all the target memory space	
	Reserved		Default region: Level 0	
	BASE_ADDR[63:10]	Hard coded	Target-dependent	
L3_PM_REQ_INFO_PERMISSION_i (i=0)	REQ_INFO[15 :0]	Yes	Type of access permitted. See Table 9-22 .	
L3_PM_READ_PERMISSION_i (i=0)	READ_PERMISSION[15:0]	Yes	Initiator read permission, depending on connections. See Table 9-14 .	
L3_PM_WRITE_PERMISSION_i (i=0)	WRITE_PERMISSION[15:0]	Yes	Initiator write permission, depending on connections. See Table 9-14 .	

Table 9-23. L3 Firewall Permission-Setting Registers (continued)

Register Name	Register Field Name	Field Modifiability	Parameter Comments	Region Comments
Region 1-7				
L3_PM_ADDR_MATCH_K	ADDR_SPACE[2:0]	Yes		The default settings can be changed only with correct access based on the L3 RT register.
	SIZE [7:3]	Yes	The regions are power-of-two in size and size-aligned with Base_Addr reference. When Size = 0x0, the firewall is deactivated.	
	LEVEL[9]	Yes	Protection region level 0x0: Level 1 0x1: Level 2 Region 1 is always Level 3.	
	BASE_ADDR[63:10]	Yes	Target-dependent	
L3_PM_REQ_INFO_PERMISSION_i	REQ_INFO[15 :0]	Yes	Type of access permitted. See Table 9-22 .	
L3_PM_READ_PERMISSION_i	READ_PERMISSION[15:0]	Yes	Initiators read permission ,depending on connections. See Table 9-14 .	
L3_PM_WRITE_PERMISSION_i	WRITE_PERMISSION[15:0]	Yes	Initiators write permission, depending on connections. See Table 9-14 .	

9.2.3.3.6 L3 Firewall Error-Logging Registers

[Table 9-24](#) lists the L3 firewall error-logging registers.

Table 9-24. L3 Firewall Error Logging Registers

Register Name	Register Field Name	Field Modifiability	Parameter Comments
L3_PM_ERROR_LOG	CMD[2:0]	Read only	Log the OCP command of the request that caused a protection violation. See Table 9-1 .
	REGION[6:4]	Read only	Log the region number targeted by the request that caused the protection violation.
	INITIATOR_ID[15:8]	Read only	Log the InitiatorID request that caused the protection violation. See Table 9-19
	REQ_INFO[20:16]	Read only	Log the MReqInfo bits of the request that caused the protection violation. See Table 9-22 .
	CODE[27:24]	Read/write	Log the error that occurred. See Table 9-26 .
	MULT[31]	Read/write	If a second error is detected before the first is cleared, the MULT bit is set. Once set by hardware, the CODE and MULT bits can be cleared only by software or a full hardware reset. Software clears the CODE and MULT bits by writing a non-zero value to the CODE field and writing 1 to the MULT bit.

9.2.3.3.7 L3 Firewall and System Control Module

When a protection violation occurs, an interrupt is sent to the MPU and IVA2.2 interrupt controller (if enabled). An in-band error is sent back, and an out-band error is logged in the CONTROL.CONTROL_PROT_ERR_STATUS register. Two logging registers are used, depending on the functional mode:

- In application mode:
 - CONTROL.CONTROL_PROT_ERR_STATUS [00]: OCM-ROM protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS [01]: OCM-RAM protection violation

- CONTROL.CONTROL_PROT_ERR_STATUS [02]: GPMC protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [04]: SMS protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [05]: MAD2D protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [06]: IVA2.2 protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [07]: L4-Core protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [12]: L3 RT protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [15]: SAD2D protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [16]: L4-Per protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [17]: L4-Emu protection violation
- In debug mode:
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [00]: OCM-ROM protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [01]: OCM-RAM protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [02]: GPMC protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [03]: SMS protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [05]: MAD2D protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [06]: IVA2.2 protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [12]: L3 RT protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG[16]: L4-Per protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG[17]: L4-Emu protection violation

When a violation occurs, these bits are cleared when the L3 or L4 firewall embedded error log registers are cleared.

9.2.3.4 Error Handling

9.2.3.4.1 Error Detection and Logging

The L3 interconnect provides mechanisms for the detection, logging, and distribution of module-detected and internal interconnect errors. Hardware support is provided to assist in logging errors and cleaning up the state to allow error recovery software to run.

Two types of errors are identified by the L3 interconnect:

- Errors detected by modules and passed along by the interconnect:
 - SResp error: Using the SResp in-band qualifier from the target, the initiator is informed that its request was unsuccessful (see [Table 9-3](#)). This error is nonspecific and further analysis is required to find its cause.
 - SError: This out-of-band qualifier reports that the target is denied service due to an internal cause. No further analysis can be done in the L3 itself.
- Errors detected by the L3 interconnect:
 - Unsupported command: This error reports that the initiator sent a command that cannot be processed, because the target cannot accept it and no conversion to another command is possible. This error is detected only once per burst.
 - Address hole: This error reports an unknown address for a request. The address map is local to each IA; therefore, an address hole error is reported each time an initiator requests an access to a target it is not logically connected to, even if this address exists in the global L3 address map. This error is detected only once per burst.
 - Protection violation: This error indicates a request was rejected by a firewall.
 - Requests time-out: This error reports that the target did not accept (if no response expected) or did not respond to the request presented by the interconnect TA. In this case, all new requests to this TA will be answered with SResp = ERR.
 - Response time-out: This error reports that the initiator did not accept response from the interconnect IA in the correct time interval (applies only to masters that have response flow control

capabilities). In this case, the IA sends burst close transactions to TAs that have open transactions from this IA. Any new request from this initiator is refused.

- Burst open time-out: This error reports that a burst or ReadEx/Write pair has been started to the interconnect IA by the initiator but did not finish in the correct time interval. If the time interval for any command exceeds the time-out period, a time-out occurs. The initiator does not complete a burst or ReadEx/Write pair. The interconnect IA then closes the transaction by a burst close transaction, to allow traffic from other initiators to resume. Burst close is logged in the interconnect TA when received.

[Figure 9-7](#) shows a global view of the register link to the error reporting structure in an initiator and the target agents.

Figure 9-7. L3 Error Reporting Structure

intc-023

Most errors are reported to the IA that originated the request, except for the following:

- Initiator time-outs are reported only out-of-band. Any time-out in the IA results in flagging it as unavailable. A software reset of the agent is required to accept any new requests from the attached core.

- Posted write request, because the IA immediately generates a valid response to the initiator core. This error is only in out-of-band.

[Table 9-25](#) lists where the errors are detected and logged.

Table 9-25. Error Types

Error	Detection	Logging	In-Band Report	Out-of-Band Report
SResp error	None needed	At IA	Yes ⁽¹⁾	Yes
SError assertion from target	None needed	At TA	No	Yes
Unsupported command	At IA	At IA	Yes	Yes
Address hole	At IA	At IA	Yes	Yes
Protection violation	At TA	At protection mechanism agent	Yes ⁽¹⁾	Yes
Response time out	At IA	At TA	No	Yes
Request time-out	At TA	At IA	No	Yes
Burst time-out	At IA	At IA	No	Yes

⁽¹⁾ In case of a posted write, errors cannot be reported in-band.

The time-out errors (request/response and burst) are persistent and require the software to reset both the module and the agent. No request can be processed in the agent until the reset is performed.

Other errors affect only the current request. Subsequent requests are treated normally. Errors are logged, however, and the information about the error used for debugging is kept until the software acknowledges the error.

[Table 9-26](#) lists the information logged for each error code. Information logged in the two error-logging registers ([L3_IA_ERROR_LOG](#), [L3_IA_ERROR_LOG_ADDR](#), [L3_TA_ERROR_LOG](#) and [L3_TA_ERROR_LOG_ADDR](#) for each IA and TA) depends on the error itself. The CODE field ERROR_LOG[27:24] identifies the type of error occurring for the IA and TA.

Table 9-26. CODE Field Definition

CODE[3:0]	Error Type	Type of Agent			Information Logged					
		IA	TA	PM	REQ_INFO	Secondary	InitiatorID	CMD	Address	
0	No error	x	x							
1	Unsupported command	x			x	x	x	x	x	
2	Address hole	x			x	x	x	x	x	
3	Protection violation			x	x		x	x		
4	In-band error	x				x	x			
5		Not used								
6		Not used								
7	Request time-out not accepted		x		x		x	x	x	
8	Request time-out, no response		x				x			
9-15		Not used								

9.2.3.4.2 Time-Out

A time-out mechanism can be enabled in the target agent and initiator agent register. When the mechanism is enabled for a target agent or initiator agent and commands are not accepted or responses are not returned within the expected delay, the L3 interconnect generates an error event.

The error is logged in the target agent REQ_TIMEOUT bit [L3_TA_AGENT_STATUS](#)[8] for a target agent time-out, the BURST_TIMEOUT bit [L3_IA_AGENT_STATUS](#)[16] bit for an initiator burst time-out, and the RESP_TIMEOUT bit [L3_IA_AGENT_STATUS](#)[8] for an initiator response time-out. The affected agent enters an error state that causes it to send error responses to any new request. To recover from this state, the target agent must be reset by system software.

The time-out is counted starting from the moment a command is presented to the target, whatever the target response to this command is. The L3 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected target agents. These four signals are referred to as 1x time-base, 4x time-base, 16x time-base, and 64x time-base.

The time-base circuit offers four possible sets of four time-base signals selected by programming the TIMEOUT_BASE field [L3_RT_NETWORK_CONTROL](#)[10:8]. [Table 9-27](#) lists all of the values in the number of L3 clock cycles.

Each target agent can be programmed to refer to one of the four time-base signals. A time-out condition is detected when either the command acceptance or the response is not received after a delay of between one and three time-base periods. After the time-out is detected and logged, the behavior of the attached module is ignored. A new request to the module arriving at the timed-out target agent receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, the software is assumed to reset first the faulty module using its internal soft-reset bit, and then the agent using software reset.

Table 9-27. L3 Timeout Register Target and Agent Programming

REQ_TIMEOUT[2:0], BURST_TIMEOUT[2:0], and RESP_TIMEOUT[2:0]					
TIMEOUT_BASE[2:0]	0	1	2	3	4
0	All L3 time-out features are disabled.				
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16384
3		1024	4096	16384	65536
4		4096	16384	65536	262144

9.2.3.4.3 Error Steering

The error reporting structure consist of errors logged individually in the initiator or TAs. Some errors can be enabled and reported out-of-band by setting the following bits to 1:

- [L3_IA_AGENT_CONTROL.BURST_TIMEOUT REP](#) bit for burst time-out
- [L3_IA_AGENT_CONTROL.RESP_TIMEOUT REP](#) bit for response time-out
- [L3_TA_AGENT_CONTROL.REQ_TIMEOUT REP](#) bit for request time-out
- [L3_TA_AGENT_CONTROL.SERROR REP](#) bit for request time-out

Setting the [L3_IA_AGENT_CONTROL.ALL_INBAND_ERROR REP](#) bit causes all in-band errors returned to the IA to be reported out-of-band.

IAs connected to processors capable of generating the debug-flagged requests (the MPU and IVA2.2 subsystems) use error steering. Any error linked to an application (nondebug) request is qualified as primary; any error linked to a debug request is qualified as secondary. Setting the IA.INBAND_ERROR_PRIMARY REP or INBAND_ERROR_SECONDARY REP bit to 1 allows the reporting of in-band to out-of-band primary and secondary errors.

The level of the current error is indicated in SECONDARY bit [L3_IA_ERROR_LOG](#)[30]. If an error occurs while another error is pending, the following occurs:

- If the pending error is primary, the new error is discarded at the IA level. MULTI bit [L3_IA_ERROR_LOG](#)[31] is set in the initiator error log register to indicate that another error has been detected; no further information can be stored.
- If both the pending error and the new error are secondary, the latest error is discarded and MULTI bit [L3_IA_ERROR_LOG](#)[31] is set.

- If the pending error is secondary and the incoming error is primary, MULTI bit [L3_IA_ERROR_LOG\[31\]](#) is set and all useful information about the new error (MCmd, MAddr, MReqInfo, etc.) is stored. All information relative to the secondary error is discarded.

For protection violation, errors are detected at the TA and steered to the control module (see [Section 9.2.3.3.7, L3 Firewall and System Control Module](#)).

9.2.3.4.4 Global Error Reporting

An out-of-band error refers to any flag output from the L3. It is not a formal error in the sense that it is not processed directly by the interconnect module; however, it is interpreted as such by one or several processors, typically by mapping it to an interrupt controller. All L3 out-of-band errors are ORed together and the result is transmitted to one or several interrupt controllers. All out-of-band errors are active high and must be acknowledged through a register access to be deasserted.

Out-of-band errors are reported through error or flag signals, asynchronously to any other data flow, but synchronously to the clock.

All errors are reported out-of-band to the IVA2.2 and MPU subsystems simultaneously. The processors must check whether an error is relevant to the subsystems. These errors are routed not only to the IVA2.2 and MPU subsystem interrupt controllers, but also to their emulation logic (see [Figure 9-8](#)). Two composite flags help in asserting the error origin and criticality:

- The L3 application error flag reports application or nonattributable (not related to a request such as a time-out, SError) errors.
- The L3 debug error flag reports debug errors.

Figure 9-8. Global Error Routing

intc-011

In addition to the SResp qualifier error reporting, some external targets use an SError signal to indicate that an internal error has occurred. Some resetting action may be required before any new request can be accepted, depending on the module and on the error itself. These signals are routed as flags internally to the L3. [Table 9-28](#) lists the possible errors reported through an SError, propagated externally to the L3 application error flag.

Table 9-28. L3 External Input Flags

Target	Flag	Description	Software Visible?
GPMC	SError	General-purpose error occurs in GPMC module	Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24]
SGX master	MError	General-purpose error occurs in SGX master	Yes, in FLAG_STATUS register and in L3 IA MERROR bit AGENT_STATUS[24]
SGX target	SError	General-purpose error occurs in SGX target	Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24]

NOTE: The user must ensure that the corresponding IRQ lines are set correctly in the interrupt controllers of the MPU and IVA2.2 subsystems.

Figure 9-9 shows the routing of errors to the application and debug error composite flags. Because both debug capable processors, the MPU and IVA2.2 subsystems have access to the full error report mechanism; they can be debugged independently of one another.

Figure 9-9. L3 Error Routing

Table 9-29 lists the bit and source for the STATUS bit field [L3_SI_FLAG_STATUS_0\[63:0\]](#) for an application error, and Table 9-30 lists the bit and source for the STATUS bit field [L3_SI_FLAG_STATUS_1\[63:0\]](#) for an application error for a debug error.

Protection errors are reported in-band to the IA when possible. This may not be possible for posted writes, however. These errors are also reported asynchronously to the module.

Additionally, all protection errors (even posted writes) are seen by the in-band-to-out-of-band conversion logic in the IAs. Therefore, all protection errors feed into the L3 application error and L3 debug error composite flags, and hence back to the MPU and IVA2.2 subsystems.

The SMS, L4-Core, L4 Per, and L4-Emu interconnects have internal firewalls that use the same reporting scheme. These errors are not routed directly to the L3 interconnect but are reported in-band to the initiator, which routes them to the composite flags. The SMS, L4-Core, L4-Per, and L4-Emu interconnects always provide an error on the in-band SResp qualifier for protection violations.

Table 9-29. L3_SI_FLAG_STATUS_0 for Application Error

Flag Bit Number	Source		Flag Bit Number	Source	
	Agent	Error		Agent	Error

9.2.4 L3 Interconnect Basic Programming Model

9.2.4.1 General Recommendation

The L3 interconnect registers must be read or written with little-endian attributes; otherwise, the result is undefined.

CAUTION

Overlapping between protection regions with the same priority level leads to unpredictable behavior and must be avoided.

9.2.4.2 Initialization

At the release of power on reset, the L3 firewall default configuration enables all accesses to target modules, except for a section of the OCM ROM.

Generally, software must configure the firewall properly to avoid poor use of the hardware resources.

L3 time-out capabilities are also disabled at reset.

9.2.4.3 Error Analysis

The information required to analyze an error source is logged in several registers (see [Table 9-26](#)). The number of registers to access depends on the error source. When investigating the origin of an error, software reads a set of error log registers. At each stage, the register either states the current error or points to the next agent in which the error is logged. [Figure 9-10](#) shows the software sequence required in most cases.

Figure 9-10. Typical Error Analysis Sequence

intc-012

Errors that do not result from an in-band to out-of-band conversion can be extracted immediately from the application or debug error flag by reading the STATUS field [L3_SI_FLAG_STATUS_0\[63:0\]](#) and [L3_SI_FLAG_STATUS_1\[63:0\]](#) register; therefore, they do not require the whole analysis sequence shown in [Table 9-26](#).

When analysis leads to a TA error, software must read the initiator agent ADDR field [L3_IA_ERROR_LOG_ADDR\[39:0\]](#) to extract the TA address causing the error.

9.2.4.3.1 Time-Out Handling

This section gives information about all modules and features in the high-tier device. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

Example 1

In this example, the MPU interrupt handler detects an error from the L3 interconnect. A read access from the [L3_SI_FLAG_STATUS_0](#) register reports a value of 0x40000. As described in [Table 9-29](#), the error detected is a burst time-out from the sDMA read port.

As with any time-out error, the affected module is now considered to be out-of-service. If necessary, the error can be cleared by sending a soft reset command to the agent (set CORE_RESET bit [L3_IA_AGENT_CONTROL\[0\]](#) to 1, and then to 0). During this time the initiator is off-line. Although the rest of the system still behaves normally, a time-out error is usually severe enough to require a complete reset of the chip.

Before resetting the agent or the system, the error log registers can learn the status of the interconnect and determine the type of failure. Reading the [IA_SDMA_RD.L3_IA_AGENT_STATUS](#) register shows whether the time-out was detected during a burst or during a read/write sequence.

Example 2

In this example, the MPU interrupt controller detects an error from the L3 interconnect. A read access from the [L3_SI_FLAG_STATUS_0](#) register reports a value of 0x100. This is a functional error from the IVA2.2 subsystem initiator.

The [IA_IVA2.2.L3_IA_ERROR_LOG](#) register should be read next. The value stored in it is 0x12_0400_1302.

- CMD field [IA_IVA2.2.L3_IA_ERROR_LOG\[2:0\]](#): Value 0x2. Not applicable for an in-band error.
- INITID field [IA_IVA2.2.L3_IA_ERROR_LOG\[15:8\]](#): Value 0x13. The origin of the error is the IVA2.2 subsystem sDMA.
- CODE field [IA_IVA2.2.L3_IA_ERROR_LOG\[27:24\]](#): Value 0x4. Error is an in-band error.
- SECONDARY bit [IA_IVA2.2.L3_IA_ERROR_LOG\[30\]](#): Value 0x0. The error is functional.
- MULTI bit [IA_IVA2.2.L3_IA_ERROR_LOG\[31\]](#): Value 0x0. No additional error has been detected.
- REQ_INFO field [IA_IVA2.2.L3_IA_ERROR_LOG\[43:32\]](#): Value 0x12. Not applicable for an in-band error.

There is no simple way to determine which target originated the in-band error. An SError assertion or a request time-out would have been detected and logged in the [L3_SI_FLAG_STATUS_0](#) register. Because no such error is asserted (bits 60:48 are still 0), the error can only be a firewall error or have originated in the target itself. The user must read all of the [PM_xxx.L3_PM_ERROR_LOG](#) registers.

CAUTION

The PM register blocks are sensitive registers and are usually protected. Ensure that the processor used to debug the error is allowed to access these registers. If not, the access will be rejected and another error will be generated.

All [PM_xxx.L3_PM_ERROR_LOG](#) registers are clear (bits 27:24 equal 0x0) except for [PM_OCMRAM.L3_PM_ERROR_LOG](#), which reads 0x0302_1301. The error occurred while trying to access the OCM RAM.

NOTE: If all [PM_xxx.L3_PM_ERROR_LOG](#) registers are clear, the error is unrelated to the interconnect. Further analysis must be done in the targets.

- Bits 27:24: Value 0x3. There is a protection error.
- Bits 2:0: Value 0x1. The command was a posted write.
- Bits 6:4: Value 0x0. The address is protected by Region 0 (default region) of the firewall.
- Bits 15:8: Value 0x13. The origin of the error is the IVA2.2, thread 2. This is consistent with the error log on the initiator side, and confirms this error report is the correct one.
- Bits 20:16: Value 0x2. The protection parameters were data, debug, and user.
- Bit 31: Value 0x0. This is the only error detected.

A check on the protection configuration confirms that this access was not allowed, either because the initiator was not given write access or because the protection access parameters were not compatible with the PM_OCMRAM.REQINFO_PERMISSIONS_0 settings.

A protection violation is not terminal from the interconnect point of view. If the module responsible for the global chip protection do not reset the system (including the IVA2.2 subsystem and the OCM RAM), it continues to run normally. A simple clearing of the error on both the IA and PM sides is required to return to a clean status.

9.2.4.3.2 Acknowledging Errors

Time-out errors can never be acknowledged. To return to a normal operation after an error, the faulty agent must be reset. An agent can be reset by asserting CORE_RESET bit [L3_IA_AGENT_CONTROL\[0\]](#) or [L3_TA_AGENT_CONTROL\[0\]](#), or by resetting the L3 interconnect through the PRCM.

Functional errors, including an in-band signal reporting a protection error, must be inactivated through software. Setting the INBAND_ERROR_PRIMARY and INBAND_ERROR_SECONDARY bits [L3_IA_AGENT_STATUS\[28:29\]](#) in an IA, or setting the SERROR bit [L3_IA_AGENT_STATUS\[24\]](#) in a TA clears the reported error. [Table 9-31](#) lists the bit to clear and the associated type of error.

The [L3_IA_ERROR_LOG](#) or [L3_TA_ERROR_LOG](#) register must also be cleared by writing a nonzero value simultaneously to the CODE bit field and the values currently stored in the MULTI and SECONDARY fields.

Table 9-31. Error Clearing

Agent Type	Error	Register Field
Initiator	In-band primary (application) error	INBAND_ERROR_PRIMARY
	In-band secondary (debug) error	INBAND_ERROR_SECONDARY
Target	Target asserts SError	SERROR

The procedure to clear protection errors depends on the system protection configuration:

- Write a nonzero value simultaneously into CODE bit field [L3_PM_ERROR_LOG\[27:24\]](#) and the value currently stored in the MULTI bit [L3_PM_ERROR_LOG\[31\]](#) of the corresponding PM register block.
- Alternately, read either [L3_PM_ERROR_CLEAR_SINGLE](#) or [L3_PM_ERROR_CLEAR_MULTI](#), depending on the current value of the MULTI field in the [L3_PM_ERROR_LOG](#) register. This solution, which allows the clearing of protection errors without having a write access on other protection registers, preserves protection.

[L3_SI_FLAG_STATUS_0](#) or [L3_SI_FLAG_STATUS_1](#) must be checked at the end of any error acknowledging sequence to confirm that the acknowledgement was successful and that no other error is pending.

9.2.4.4 Typical Example of Firewall Programming Example

All four regions in the IVA2.2 target firewall can be configured with no restrictions. However, protection is required for a 14K-byte region starting at address 0x0 in address space 2, and it must accept any access from any initiator for the rest of the target. The protection restricts allowed accesses as follows:

- Only the IVA2.2 and the MPU can read from this memory.
- Only the MPU can write to this memory.
- The protection parameters must include supervisor and functional.

Only accesses declared as supervisor and functional are allowed to pass through the protected region of the firewall. There is no restriction on other attributes.

[Table 9-32](#) lists the possible parameter combinations, whether they are allowed to pass or not, and why they are rejected.

Table 9-32. MReqInfo Parameter Example

Reqbit	MReqInfo				
	MReqSupervisor	MReqDebug	MReqType	Access Allowed	Reason for Rejection
0	User	Functional	Data	No	Not supervisor
1	User	Functional	Code	No	Not supervisor
2	User	Debug	Data	No	Not supervisor
3	User	Debug	Code	No	Not supervisor
4		Reserved for non-GP devices		No	
5		Reserved for non-GP devices		No	
6		Reserved for non-GP devices		No	
7		Reserved for non-GP devices		No	
8	Supervisor	Functional	Data	Yes	
9	Supervisor	Functional	Code	Yes	
10	Supervisor	Debug	Data	No	Not functional
11	Supervisor	Debug	Code	No	Not functional
12		Reserved for non-GP devices		No	
13		Reserved for non-GP devices		No	
14		Reserved for non-GP devices		No	
15		Reserved for non-GP devices		No	

Only combinations with codes 8 and 9 are allowed to access a target. REQ_INFO field PM_IVA2.2.[L3_PM_REQ_INFO_PERMISSION_i](#)[15:0] for the protected region must be set to (0x8) | (0x9); that is, 0x0300.

Solution 1

Set Region 0 to accept all accesses:

- PM_IVA2.2.[L3_PM_REQ_INFO_PERMISSION_i](#) (i=0)= 0xFFFF
- PM_IVA2.2.[L3_PM_READ_PERMISSION_i](#) (i=0)= 0x140E
- PM_IVA2.2.[L3_PM_WRITE_PERMISSION_i](#) (i=0)= 0x140E

Set Region 1 to cover the first 8K bytes of the protected region:

- PM_IVA2.2.[L3_PM_ADDR_MATCH_k](#) (k=1) = 0x22 (start address 0x0, size 8K bytes, address space 2)
- PM_IVA2.2.[L3_PM_REQ_INFO_PERMISSION_i](#) (i=1) = 0x0300
- PM_IVA2.2.[L3_PM_READ_PERMISSION_i](#) (i=1) = 0x0406 (IVA2.2 DMA and MMU and MPU are allowed)
- PM_IVA2.2.[L3_PM_WRITE_PERMISSION_i](#) (i=1) = 0x0002 (only MPU is allowed to write)

Set Region 2 to cover the next 4K bytes:

- PM_IVA2.2.[L3_PM_ADDR_MATCH_k](#) (k=2) = 0x201A (start address 0x2000, level 1, size 4K bytes, address space 2)
- PM_IVA2.2.[L3_PM_REQ_INFO_PERMISSION_i](#) (i=2) = 0x0300
- PM_IVA2.2.[L3_PM_READ_PERMISSION_i](#) (i=2) = 0x0406
- PM_IVA2.2.[L3_PM_WRITE_PERMISSION_i](#) (i=2) = 0x0002

Set Region 3 to cover the last 2K bytes:

- PM_IVA2.2.[L3_PM_ADDR_MATCH_K](#) (k=3)= 0x3012 (start address 0x3000, level 1, size 2K bytes, address space 2)
- PM_IVA2.2.[L3_PM_REQ_INFO_PERMISSION_i](#) (i=3) = 0x0300
- PM_IVA2.2.[L3_PM_READ_PERMISSION_i](#) (i=3) = 0x0406
- PM_IVA2.2.[L3_PM_WRITE_PERMISSION_i](#) (i=3) = 0x0002

[Figure 9-11](#) shows the firewall configuration for Solution 1.

Figure 9-11. Firewall Configuration Solution 1

Solution 2

Set Region 0 to accept all accesses:

- PM_IVA2.2.[L3_PM_REQ_INFO_PERMISSION_i](#) (i=0) = 0xFFFF
- PM_IVA2.2.[L3_PM_READ_PERMISSION_i](#) (i=0) = 0x140E
- PM_IVA2.2.[L3_PM_WRITE_PERMISSION_i](#) (i=0) = 0x140E

Set Region 2 to cover 16K bytes:

- PM_IVA2.2.[L3_PM_ADDR_MATCH_K](#) (k=2) = 0x2A (start address 0x0, level 1, size 16K bytes, address space 2)
- PM_IVA2.2.[L3_PM_REQ_INFO_PERMISSION_i](#) (i=2) = 0x0300
- PM_IVA2.2.[L3_PM_READ_PERMISSION_i](#) (i=2) = 0x0406 (IVA2.2 DMA and MMU and MPU are allowed)
- PM_IVA2.2.[L3_PM_WRITE_PERMISSION_i](#) (i=2) = 0x0002 (only MPU is allowed to write)

Set Region 1 to mask the last 2K bytes:

- PM_IVA2.2.[L3_PM_ADDR_MATCH_K](#) (k=2) = 0x3812 (start address 0x3800, size 2K bytes, address space 2)
- PM_IVA2.2.[L3_PM_REQ_INFO_PERMISSION_i](#) (i=1) = 0xFFFF
- PM_IVA2.2.[L3_PM_READ_PERMISSION_i](#) (i=1) = 0x042E
- PM_IVA2.2.[L3_PM_WRITE_PERMISSION_i](#) (i=1) = 0x042E

[Figure 9-12](#) shows the firewall configuration for Solution 2.

Figure 9-12. Firewall Configuration Solution 2

9.2.5 L3 Interconnect Register Manual

Table 9-33 lists the base address and address space for all L3 register blocks.

Table 9-33. Instance Summary

Module Name	Base Address	Size
RT	0x6800 0000	1K byte
SI	0x6800 0400	1K byte
IA_MPUS	0x6800 1400	1K byte
IA_IVA2.2	0x6800 1800	1K byte

9.2.5.1 L3 Initiator Agent (L3 IA)

This section describes the IA register block. Each IA in L3 interconnect has its own IA register block.

The following are the IA registers:

- MPU subsystem port
- IVA2.2 subsystem port
- SGX subsystem port
- High-Speed USB Host
- High-Speed USB OTG
- System DMA read port
- System DMA write port
- Display subsystem port
- Camera subsystem port
- DAP port

- Die-to-die

[Table 9-34](#) through [Table 9-37](#) list the IA registers and their physical addresses, depending on the module instance.

Table 9-34. Initiator Agent Common Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	IA_MPUSS Physical Address	IA_IVA2.2 Physical Address	IA_SGX Physical Address
L3_IA_COMPONENT	R	64	0x000	0x6800 1400	0x6800 1800	0x6800 1C00

9.2.5.2 L3 Target Agent (L3 TA)

This section describes the TA register block. Each TA in L3 interconnect has its own register block.

The following are the TA registers:

- SDRAM memory scheduler (TA_SMS module)
- General-purpose memory controller (TA_GPMC module)
- On-chip memory RAM (TA_OCM_RAM module)
- On-chip memory ROM (TA_OCM_ROM module)
- Master D2D (TA_MAD2D module)
- IVA2.2 subsystem (TA_IVA2.2 module)
- SGX subsystem (TA_SGX module)
- L4-Core interconnect (TA_L4_CORE module)
- L4-Per interconnect (TA_L4_PER module)
- L4-Emu interconnect (TA_L4_EMU module)

[Table 9-50](#) through [Table 9-53](#) lists all initiator target registers and their physical addresses depending on the module instance.

[Table 9-54](#) through [Table 9-64](#) describe the individual common registers in the module instance.

Table 9-50. Target Agent Common Register Summary

9.2.5.4 Protection Mechanism (PM)

This section describes the protection mechanism register block.

The following are the protection mechanism registers:

- Register target (PM_RT module)
- General-purpose memory controller (PM_GPMC module)
- On-chip RAM (PM_OCM_RAM module)
- On-chip ROM (PM_OCM_ROM module)
- IVA2.2 subsystem (PM_IVA2.2 module)

[Table 9-75](#) and [Table 9-77](#) list the protection registers and their physical addresses, depending on the module instance.

[Table 9-78](#) through [Table 9-88](#) describe the individual common registers in the module instance.

Table 9-75. Protection Mechanism Common Register Summary

Register Name	Type	Register Width (Bits)	PM_RT Physical Address	PM_GPMC Physical Address
L3_PM_ERROR_LOG	RW	64	0x6801 0020	0x6801 2420

9.3 L4 Interconnects

9.3.1 Overview

To connect peripheral modules, the device uses four separate L4 interconnect structures. Although all L4 interconnects handle transfers with peripherals, the interconnects are in different power domains. The L4 interconnect is composed of the following:

- L4-Core: Includes the majority of the peripherals and the configuration interface for L3 interconnect system modules
- L4-Per: Includes peripherals that do not need to be mapped in the CORE power domain
- L4-Wakeup: Includes the peripherals attached to the WKUP power domain
- L4-Emu: Includes emulation peripherals attached to the EMU power domain

The following are the main features of the L4 interconnects:

- Single port to connect to L3 interconnect
 - L4-Core
 - L4-Per
- Dual ports for the following:
 - L4-Emu to connect to the L3 interconnect and DAP
 - L4-Wakeup to connect to the L4-Core and L4-Emu
- Single 32-bit initiator for the L3 port
- Multitarget ports (one per target interface on the L4 interconnect)
- 8-, 16-, or 32-bit data, single, or burst transactions
- Little-endian
- Nonblocking with fair arbitration between threads
- Peripherals are not burst-capable; the system initiators can address bursts to them, but the L4 interconnect breaks the bursts into single accesses.
- Target interfaces: Fully synchronous or divided synchronous
- Peak bandwidth of L4 interconnect is $1 \text{ MBps} \times \text{L4 frequency in MHz}$ per L4 thread (that is, 100 MBps, when the L4 frequency is 100 MHz).
- Latency: Three cycles on request, one cycle on response
- Protection logic provides user-configurable access control to targets by each initiator:
 - Firewall in L4-Core protects the core and wake-up peripherals.
 - Firewall in L4-Per protects per peripherals.
 - Firewall in L4-Emu protects emulation and wake-up peripherals

NOTE: L4-Wakeup has two input ports from L4-Core and L4-Emu. Therefore, wake-up peripherals appear in two locations in the memory mapping. Normally, L4-Emu limits its access except when debugging.

NOTE: L4_CORE has four threads (maximum), L4_PER has four threads (maximum), and L4_EMU and L4_WKUP have one thread.

Figure 9-13 shows an overview of the L4 interconnects and the peripherals attached to them.

Figure 9-13. L4 Interconnect Overview

Figure 9-14 shows an internal view of the L4 interconnects in the overall interconnect. This architecture, with only one initiator module (the initiator subsystem) distributing transactions to all target modules (peripherals), enables the firewall functions of the L4 interconnects to be centralized at the L4 initiator level. The L4 firewall filters the accesses according to the configurable protection groups defined in the L4 address protection (AP) registers. Each module or agent is assigned to a protection group. Configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

Figure 9-14. L4 Initiator-Target Connectivity for L4-Core and L4-Per

NOTE: As [Figure 9-14](#) shows, targets are attached to branches. These branches have no functional effect and are present for timing closure reasons only.

9.3.1.1 L4-Core Interconnect

The L4-core interconnect handles only transfers to peripherals in the CORE power domain. [Table 9-104](#) lists the TAs.

Table 9-104. L4-Core Target Agents

Module Name	Description
Display subsystem	Display subsystem configuration port
Camera subsystem	Camera subsystem port
USBHS OTG	Universal serial bus High-Speed port OTG
USBHS Host	Universal serial bus High-Speed port Host
USBTLL	USB Transceiver Less Link
UART1	Universal asynchronous receiver transmitter port 1
UART2	Universal asynchronous receiver transmitter port 2
I2C1	Multimaster inter-integrated circuit 1
I2C2	Multimaster inter-integrated circuit 2
I2C3	Multimaster inter-integrated circuit 3
McBSP1	Multichannel buffered serial port 1
McBSP5	Multichannel buffered serial port 5
GPTIMER10	General-purpose timer 10
GPTIMER11	General-purpose timer 11
MMC1	Multimedia memory controller SDIO 1
MMC2	Multimedia memory controller SDIO 2
MMC3	Multimedia memory controller SDIO 3
HDQ/1-Wire	Single wire serial link low rate
MLB (mailbox)	Mailbox
MCSPI1	Serial peripheral interface 1
MCSPI2	Serial peripheral interface 2
MCSPI3	Serial peripheral interface 3
MCSPI4	Serial peripheral interface 4
SR1	SmartReflex1
SR2	SmartReflex2
sDMA	System DMA controller
L4-Wakeup	L4-Wakeup interconnect
CM	Clock manager
SCM	System control module

NOTE: A unique port is used for communication between the L3 interconnect and the L4-Core interconnect to allow the L3 initiators to access the L4-Core targets.

For the list of initiators authorized to access the L4-Core peripherals, see [Table 9-14](#). For details on restricted access, see [Section 9.3.3.3.1, Protection Mechanism](#).

9.3.1.2 L4-Per Interconnect

The L4-Per interconnect handles only transfers to peripherals in the PER power domain. [Table 9-105](#) lists the TAs.

Table 9-105. L4-Per Target Agents

Module Name	Description
UARTIrDA	Universal asynchronous receiver/transmitter and infrared data association port

Table 9-105. L4-Per Target Agents (continued)

Module Name	Description
UART4	Universal asynchronous receiver transmitter port 4
McBSP2	Multichannel buffered serial port 2
McBSP3	Multichannel buffered serial port 3
McBSP4	Multichannel buffered serial port 4
GPTIMER2	General-purpose timer 2
GPTIMER3	General-purpose timer 3
GPTIMER4	General-purpose timer 4
GPTIMER5	General-purpose timer 5
GPTIMER6	General-purpose timer 6
GPTIMER7	General-purpose timer 7
GPTIMER8	General-purpose timer 8
GPTIMER9	General-purpose timer 9
GPIO2	General-purpose I/O 2
GPIO3	General-purpose I/O 3
GPIO4	General-purpose I/O 4
GPIO5	General-purpose I/O 5
GPIO6	General-purpose I/O 6

NOTE: A unique port is used for communication between the L3 interconnect and the L4-Core interconnect to allow the L3 initiators to access the L4-Per targets.

For the list of initiators authorized to access the L4-Per peripherals, see [Table 9-14](#). For details on restricted access, see [Section 9.3.3.3.1, Protection Mechanism](#).

9.3.1.3 L4-Emu Interconnect

The L4-Emu interconnect handles only transfers to peripherals in the EMU power domain. [Table 9-106](#) lists the TAs.

Table 9-106. L4-Emu Target Agents

Module Name	Description
L4-Wakeup	L4-Wakeup interconnect
SDTI	System debug trace interface
ETB	Embedded trace buffer
TPIU	Trace port interface unit
MPU	ARM9
DAP	Debug access port

Not all initiators can access all the targets in the L4-Emu interconnect. Additional restrictions affect the ability of these initiators to access the L4-Emu peripherals. [Table 9-107](#) lists which initiators can access the L4-Emu interconnect.

NOTE: For the list of initiators authorized to access the L4-Emu peripherals, see [Table 9-14](#). For details on restricted access, see [Section 9.3.3.3.1, Protection Mechanism](#).

Table 9-107. L4-Emu Initiator Agents

Module Name	Description
L3 interconnect	L3 interconnect port
DAP	DAP port

9.3.1.4 L4-Wakeup Interconnect

The L4-Wakeup interconnect handles only transfers to peripherals in the WKUP power domain. [Table 9-108](#) lists the TAs.

Table 9-108. L4-Wakeup Target Agents

Module Name	Description
PRM	Power reset manager
GPIO1	General-purpose I/O 1
GPTIMER1	General-purpose timer 1
WDTIMER2	MPU subsystem watchdog timer
32KTIMER	32-kHz timer

Initiators that can access the L4-Core or L4-Emu can access all the targets in the L4-Wakeup interconnect. [Table 9-109](#) lists the initiators that can access the L4-Wakeup interconnect. For details on restricted access, see [Section 9.3.3.3.1, Protection Mechanism](#).

Table 9-109. L4-Wakeup Initiator Agents

Module Name	Description
L4-Core interconnect	L4-Core interconnect port
L4-Emu interconnect	L4-Emu interconnect port

9.3.2 L4 Interconnects Integration

9.3.2.1 Clocking, Reset, and Power-Management Scheme

9.3.2.1.1 Clocks

Four functional clocks are used in each L4 interconnect (see [Table 9-110](#)).

Table 9-110. L4 Interconnect Clocks

Clock	Frequency	Name	Comments
L4-Core interconnect clock	Up to Core_L3_ICLK/2	CORE_L4_GICLK	Source, control, and gating handled by PRCM module
L4-Per interconnect clock	Up to Core_L3_ICLK/2	PER_L4_GICLK	Source, control, and gating handled by PRCM module
L4-Emu clock		L4_EMU	Clock for emulation
L4-Wakeup interconnect clock		WKUP_L4_GICLK	Source, control, and gating handled by PRCM module

9.3.2.1.2 Resets

9.3.2.1.2.1 Hardware Reset

L4 interconnects receive a reset signal from the PRCM module, which is the reset signal to the CORE power domain. For more details, see *Power, Reset, and Clock Management*.

[Table 9-111](#) lists the hardware reset for the L4-Core interconnect.

Table 9-111. L4 Interconnect Hardware Reset

Interconnect	Reset Domain
L4-Core interconnect	CORE_RST
L4-Per interconnect	PER_RST
L4-Wakeup interconnect	WKUP_RST
L4-Emu interconnect	EMU_RST

9.3.2.1.2.2 Software Reset

The L4 interconnects have hardware reset capabilities, but do not have software reset capabilities. The hardware reset capabilities are controlled by the PRCM module and are applied to the L4 interconnects and the connected L4 TAs and L4 target modules.

9.3.2.1.3 Power Domain

For more details on power voltage scaling, see *Power, Reset, and Clock Management*.

[Table 9-112](#) lists the power domains for the L4-Core and L4-Wakeup interconnects.

Table 9-112. L4 Interconnect Power Domains

Interconnect	Power Domain
L4-Core interconnect	CORE
L4-Per interconnect	PER
L4-Emu interconnect	EMU
L4-Wakeup interconnect	WKUP

9.3.2.1.4 Power Management

9.3.2.1.4.1 Module Power-Saving

The L4 interconnect automatically performs internal clock autogating to reduce power consumption. Though not recommended, it is possible to deactivate clock autogating by writing 1 to the CLOCK_GATE_DISABLE bit [L4_LA_NETWORK_CONTROL_H\[24\]](#) of each L4 interconnect. Clock autogating is enabled by default.

9.3.2.1.4.2 System Power Management and Wakeup

As part of the system-wide power-management scheme, the L4 interconnect enters an idle state at the request of the PRCM module (for more information, see *Power, Reset, and Clock Management*). The L4 interconnect is always in smart-idle mode; that is, it goes into idle state after receiving the request from the PRCM module once all the transfer requests are complete. This functionality is handled by hardware. The L4 interconnect sends an acknowledge signal back to the PRCM module when it enters idle state.

9.3.3 L4 Interconnects Functional Description

9.3.3.1 L4-Interconnects Initiator Identification

In the device interconnect, a ConnID is an initiator module identifier. The L4 interconnect uses the same ConnID as L3.

9.3.3.2 Endianness Management

Both L4 interconnects are little-endian only. Any initiator accessing the L4 interconnect module must consider byte ordering and perform a conversion, if necessary.

9.3.3.3 L4 Protection and Firewalls

9.3.3.3.1 Protection Mechanism

The following two parameters are used to set up access permission because of the large address spaces and the number of peripherals connected to the L4 interconnects:

- Programmable groups for initiators:
 - 8 protection groups for the L4-Core interconnect
 - 8 protection groups for the L4-Per interconnect
 - 6 protection groups for the L4-Emu interconnect
- Each segment is divided into regions of 2K bytes:
 - 100 regions for the L4-Core interconnect
 - 43 regions for the L4-Per interconnect
 - 26 regions for the L4-Emu interconnect

NOTE: Regions and segments are present for the L4-Wakeup interconnect but cannot be programmed. The L4-Wakeup protection is done through the L4-Core and L4-Emu interconnects.

A protection group is a group of targets that have the same protection settings. Initiator access is defined by CONNID_BIT_VECTOR field [L4_AP_PROT_GROUP_k_L\[15:0\]](#). The initiators have the same access permission to all regions in this group.

A region is programmed to allow access to a unique selectable protection group by using PROT_GROUP_ID field [L4_AP_REGION_I_H\[22:20\]](#).

NOTE: k denotes the protection group number.

I denotes the region number.

9.3.3.3.2 Protection Group

A protection group defines which initiators with a given MReqInfo can access the targets agent protected by this group.

The CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_MEMBERS_K[15:0] (see [Figure 9-15](#)) is a 1-bit vector that sets up initiator permission access regions. A protection group is accessible by an initiator if the bit position corresponding to its ConnID is set to one in the CONNID_BIT_VECTOR field.

The ENABLE field L4_AP_PROT_GROUP_ROLES_K[31:0] lists all possible MReqInfo combinations. Setting a Req bit in this register determines the type of access allowed to the initiator. See [Section 9.2.3.3.4, REQ_INFO_PERMISSION Configuration](#), for more information. MReqInfo is used in L4 the same way it is used in the L3 firewall configuration.

NOTE: Permissions are identical for read and write accesses in L4 interconnect targets.

[Figure 9-15](#) shows an example of CONNID_BIT_VECTOR.

Figure 9-15. Example of CONNID_BIT_VECTOR

Setting bits 1 and 4 in the PROT_GROUP_ID_1 defines a group initiator able to access targets in protection group 1, and includes:

- MPU SS
- IVA2.2 MMU

Protection group 1 (PG1) can be applied to multiple protection regions without limitation. Each protection region I that is configured with PG1 enables permission access to these two initiators only.

The firewall default configuration for the L4-Core interconnect contains eight protection groups:

- Most regions are, by default, set with protection group 7 (PG7), which is configured for all access (see [Table 9-113](#)).

- Protection group 0 (PG0) is restricted to the MPU subsystem.
- The DSS is attached to protection group 2 (PG2).
- The Camera is attached to protection group 3 (PG3).
- By default, PG5 to PG7 are configured for all access.

The L4-Per interconnect contains eight protection groups:

- By default, PG0 to PG7 are configured for all access.
- By default, most regions are set with PG7, which is configured for all access (see [Table 9-114](#)).

The L4-Emu interconnect contains six protection groups:

- By default, most regions are set with PG5, which is configured for all access (see [Table 9-115](#)).
- The AP is attached to PG0.
- The emulation organs are attached to PG3.

9.3.3.3 Segments and Regions

The protection mechanism for L4 interconnects is based on a hierarchical segmentation (see [Figure 9-16](#)). By default, some regions are attached to a specific protection group. This specificity allows the user to set up the permission access for certain types of modules that require the same access protection without managing the region allocation.

Figure 9-16. L4 Firewall Overview

All interconnect address spaces are covered by regions. [Table 9-113](#) to [Table 9-115](#) list the module mapping, including the address, region number, and default protection group allocated to it.

By setting ENABLE bit L4_AP_REGION_y_H[0] to 0, the region becomes inactive and therefore inaccessible. Setting the bit to 1 activates the region.

Table 9-113. Region Allocation for L4-Core Interconnect

Device Name	Start Address (Hex)	Description	Region Number	Default Protection Group
Reserved	0x4800 0000	Reserved		
System control module	0x4800 2000	Module	73	7
	0x4800 3000	L4 interconnect	75	7

Table 9-113. Region Allocation for L4-Core Interconnect (continued)

9.3.3.3.4 L4 Firewall Address and Protection Registers Setting

Table 9-116 lists the settings of the AP registers for an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

Table 9-116. L4 Firewall Register Description Overview

Register Type	Register Name	Bits	Field	Description
Segment	L4_AP_SEGMENT_i_L	23:0	Base	Segment base address
	L4_AP_SEGMENT_i_H	4:0	SIZE	Segment size equals to 2 power of SIZE
Protection groups	L4_AP_PROT_GROUP_MEMBERS_k_L	15:0	CONNID_BIT_VECTOR	See Section 9.3.3.1 for L4ConnID).
	L4_AP_PROT_GROUP_ROLES_k_L	15:0	ENABLE	Refer to Table 9-22 for MReq description

Table 9-116. L4 Firewall Register Description Overview (continued)

Register Type	Register Name	Bits	Field	Description
Region setting	L4_AP_REGION_I_L	23:0	BASE	Define the base address of region in respect to its respective segment base address
	L4_AP_REGION_I_H	27:24	SEGMENT_ID	Segment ID number of the region
		22:20	PROT_GROUP_ID	The protection group attached to the region
		19:17	BYTE_DATA_WIDTH_EX_P	Determine the number of bytes in an access
		5:1	SIZE	Size of the region equals to 2 power of SIZE
		0	ENABLE	Enable the region protection

9.3.3.4 Error Handling

9.3.3.4.1 Overview

The L4 interconnect provides mechanisms for handling either internally detected errors or errors reported by modules attached to the L4 target ports. Hardware support facilitates logging errors and cleaning up the state to allow error recovery software to treat the error.

As an L3 target, the L4 interconnect reports errors to the L3 interconnect in-band whenever possible. In-band error reporting is the default and recommended configuration. It is assumed that INBAND_ERROR REP bit [L4_IA_AGENT_CONTROL_L\[27\]](#) is set to 1.

NOTE: *L4_IA* denotes which interconnect is considered: L4-Core, L4-Per, L4-Emu, or L4-Wakeup.
L4_TA denotes the module name, such as UART1, McBSP1, etc.

The L4 interconnects handle three types of errors:

- No target core found or address hole
- Request protection violation
- Failure of the target to service a request before a time-out expires

9.3.3.4.2 Error Logging

9.3.3.4.2.1 No Target Core Found/Address Hole

This error indicates that a request was addressed to a hole in the L4 address map.

When this occurs, an in-band error response is returned to the L3 level.

The error is also logged into the INBAND_ERROR bit [L4_IA_AGENT_STATUS_L\[27\]](#).

Additionally, an address hole error code is logged into the CODE field [L4_IA_ERROR_LOG_L\[25:24\]](#).

The L4_IA_ERROR_LOG register also includes MULTI bit [L4_IA_ERROR_LOG_L\[31\]](#), which is asserted when multiple errors are detected. In this case, the error code corresponds to the first error that occurs.

9.3.3.4.2.2 Protection Violation

This error indicates that an initiator has accessed a restricted region. This error is reported using an in-band error. It is written to the INBAND_ERROR field. A protection violation error code is also saved in the CODE field [L4_IA_ERROR_LOG_L\[25:24\]](#).

The protection violation is also logged in the CONTROL.CONTROL_PROT_ERR_STATUS [7] register of the system control module.

NOTE: There is no specific error signal for the protection violation that goes out from the L4 interconnects. The out-band error that goes to the system control module indicates a protection violation, but it also indicates normal interconnect errors.

9.3.3.4.2.3 Time-Out

This section gives information about all modules and features in the high-tier device. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

A time-out mechanism can be enabled on a per-target basis in the [L4_TA_AGENT_CONTROL_L](#) register. If the mechanism is enabled for a TA, and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

The error is logged in the target agent REQ_TIMEOUT bit [L4_TA_AGENT_STATUS_L\[8\]](#). The affected TA enters an error state that causes it to send error responses to any new request targeted at it. To recover from this state, the TA must be reset by system software. The time-out is counted starting from the moment a command is presented to the target, regardless of how the target responds to the command.

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. These four signals are referred to as 1X-time base, 4X-time base, 16X-time base, and 64X-time base.

The time-base circuit offers four possible sets of time-base signals. Selection is done by programming TIMEOUT_BASE field [L4_LA_NETWORK_CONTROL_L\[10:8\]](#). [Table 9-117](#) lists the values in the number of L4 clock cycles.

Table 9-117. L4 Time-Out Link and TA Programming

TIMEOUT_BASE[2:0]	REQ_TIMEOUT[2:0]				
	0	1	2	3	4
0	All L4 time-out features are disabled.				
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16384
3		1024	4096	16384	65536
4		4096	16384	65536	262144

The reset value is 0x4, resulting in the longest possible time-out.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, by using REQ_TIMEOUT field [L4_TA_AGENT_CONTROL_L\[10:8\]](#) (see [Table 9-118](#)).

Table 9-118. L4 Time-Out TA Programming

REQ_TIMEOUT	Target Agent Time-Out Reference
0	Time-out locally disabled
1	1X-base cycle
2	4X-base cycle
3	16X-base cycle
4	64X-base cycle

A time-out condition is detected when the command acceptance or the response is not received after a delay of between one and three time-base periods.

Example:

- L4 frequency = 100 MHz
- TIMEOUT_BASE = 4 in the [L4_LA_NETWORK_CONTROL_L](#) register

- REQ_TIMEOUT = 2 in the [L4_TA_AGENT_CONTROL_L](#) for target agent A
- REQ_TIMEOUT = 4 in the [L4_TA_AGENT_CONTROL_L](#) for target agent B

At agent A, the time-base unit is 16384 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 164 µs to 492 µs.

At agent B, the time-base unit is 262,144 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 2.6 ms to 7.8 ms.

On detection of a time-out condition, the agent automatically generates an error response to the inter_IA, which is forwarded to the L3. The agent also logs the time-out to REQ_TIMEOUT bit [L4_TA_AGENT_STATUS_L\[8\]](#).

After the time-out has been detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, the software is assumed to reset first the faulty module by using its internal soft reset bit, and then the TA by using OCP_RESET bit [L4_TA_AGENT_CONTROL_L\[0\]](#).

9.3.3.4.3 TA Software Reset

Writing 1 to OCP_RESET bit [L4_TA_AGENT_CONTROL_L\[0\]](#) initiates the software reset period. The software reset must be asserted for at least 16 cycles of the target module OCP clock, which can be a divided clock with respect to the L4 clock.

During the software reset period the following occur:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to avoid getting unwanted errors.
- Requests sent to the TA register block are processed as usual.
- The [L4_TA_AGENT_STATUS_L\[8\]](#) REQ_TIMEOUT status bit is cleared.

Writing 0 to the [L4_TA_AGENT_CONTROL_L\[0\]](#) OCP_RESET bit terminates the software reset period.

The attached module must then be reset to complete the recovery.

9.3.3.4.4 Error Reporting

[Figure 9-17](#) illustrates the error-reporting scheme used in the L4_Core, L4_Per, and L4_EMU interconnects.

- Timeout error generation is enabled at each TA.
- Timeout error and target in-band errors are only reported in-band to the L3 initiator.
- Protection violations are reported out-of-band. Error steering is used to distinguish between application or debug errors.

Figure 9-17. L4 Error Reporting

intc-025

9.3.4 L4 Interconnect Programming Guide

9.3.4.1 L4 Interconnect Low-Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L4 interconnect module.

9.3.4.1.1 Global Initialization

9.3.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the L4 interconnect module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the L4 interconnect. For more information, see *L4 Interconnect Integration*.

Table 9-119. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For more information about the configuration of the module, see Chapter 3, Power, Reset, and Clock Management .
Control module	For more information about the configuration of the module, see Control Module .
MPU INT	The MPU INT must be configured to enable the interrupts from the L4 interconnect module. See Chapter 12, Interrupt Controllers .
sDMA	For more information about the configuration of the sDMA, see sDMA .

Table 9-119. Global Initialization of Surrounding Modules (continued)

Surrounding Modules	Comments
L3 interconnect	For more information about the interconnect configuration, see , <i>Interconnect</i> .

9.3.4.1.2 Operational Modes Configuration

9.3.4.1.2.1 L4 Interconnect Error Analysis Mode

9.3.4.1.2.1.1 Main Sequence: L4 Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

[Figure 9-18](#) and [Figure 9-19](#) show the software sequence required in most cases.

[Table 9-120](#) and [Table 9-121](#) show the main sequence for error analysis mode and its subprocess call summary, respectively.

Figure 9-18. Typical Error Analysis Sequence

9.3.4.1.2.1.2 Subsequence: L4 Interconnect Protection Violation Error Identification

This procedure describes the protection violation error identification (see [Table 9-122](#)).

Table 9-122. Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	
Read error code.	L4_IA_ERROR_LOG_L[25:24] CODE	
IF: Is it an inband error?	L4_IA_AGENT_STATUS_L[27] INBAND_ERROR REP	=0x1
Read status bits.	CONTROL.CONTROL_SEC_ERR_STATUS[17:16]	
Write 1 to clear status bits.	CONTROL.CONTROL_SEC_ERR_STATUS[17:16]	0x3
Write 1 to clear IA status bit.	L4_IA_AGENT_STATUS_L[27] INBAND_ERROR REP	0x1
ELSE		
Read status bits.	CONTROL.CONTROL_PROT_ERR_STATUS_DE BUG[17:16]	
Write 1 to clear status bits.	CONTROL.CONTROL_PROT_ERR_STATUS_DE BUG[17:16]	0x3
ENDIF		
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear MError status.	L4_IA_AGENT_STATUS_L[24] MERROR REP	0x1

9.3.4.1.2.1.3 Subsequence: L4 Interconnect Unsupported Command/Address Hole Error Identification

This procedure describes the identification of unsupported command/address hole error (see [Table 9-123](#)).

Table 9-123. Unsupported Command/Address Hole Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	
Read initiator error code.	L4_IA_ERROR_LOG_L[25:24] CODE	
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear inband error status.	L4_IA_AGENT_STATUS_L[27] INBAND_ERROR REP	0x1

9.3.4.1.2.1.4 Subsequence: L4 Interconnect Reset TA and Module

This procedure resets the TA and module (see [Table 9-124](#)).

Table 9-124. Reset TA and Module

Step	Register/Bit Field/Programming Model	Value
Reset TA.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x1
Wait until target module clock = 16 cycles.		
Write 0 to clear TA time-out status.	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	0x0
Write 0 to clear TA reset.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x0
Reset the attached module. ⁽¹⁾		

⁽¹⁾ For more information, see the respective module chapter.

9.3.4.1.2.2 L4 Interconnect Time-Out Configuration Mode

9.3.4.1.2.2.1 Main Sequence: L4 Interconnect Time-Out Configuration Mode

This procedure describes the time-out configuration sequence (see [Table 9-125](#)).

Table 9-125. Time-Out Configuration

Step	Register/Bit Field/Programming Model	Value
Disable time-out.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	0x0
Clear TA time-out error status. ⁽¹⁾	L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT	0x1
Set time-out at TA level. ⁽¹⁾	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	xxx
Set time-out base.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	xxx

⁽¹⁾ Must be done for each TA

9.3.4.1.2.3 L4 Interconnect Firewall Configuration Mode

9.3.4.1.2.3.1 Main Sequence: L4 Interconnect Firewall Configuration Mode

This procedure describes the firewall configuration sequence (see [Table 9-126](#)).

Table 9-126. Firewall Configuration

Step	Register/Bit Field/Programming Model	Value
Define the members of protection group k. ⁽¹⁾	L4_AP_PROT_GROUP_MEMBERS_K_L[15:0] CONNID_BIT_VECTOR	xxx
Define the access type of a protection group k. ⁽¹⁾	L4_AP_PROT_GROUP_ROLES_K_L[15:0] ENABLE	xx
Set region affiliation to protection group. ⁽²⁾	L4_AP_REGION_L_L[22:20] PROT_GROUP_ID	xxx

⁽¹⁾ Must be done for each protection group
⁽²⁾ Must be done for each region

9.3.5 L4 Interconnects Register Manual

A summary of the hardware interface for the L4-Core, L4-Per, L4-Emu, and L4-Wkup interconnects is given in [Table 9-127](#) through [Table 9-130](#), respectively. Each module instance in the design is shown with the module register map and bit definitions for each bit field.

Table 9-127. L4-Core Instance Summary

9.3.5.1 L4 Initiator Agent (L4 IA)

This section provides information on the L4 IA module. Each of the registers within the module instance is described separately in [Table 9-131](#) to [Table 9-132](#).

The initiator OCP interface register block (IA) consists of the status, control, and error log registers that can be used to configure the interface of an initiator OCP. There can be only one register block for each initiator OCP interface.

Table 9-131. L4 IA Register Summary (1)

Register Name	Type	Register Width (Bits)	CORE_IA Physical Address	PER_IA Physical Address	EMU_IA_L3 Physical Address
L4_IA_COMPONENT_L	R	32	0x4804 0800	0x4900 0800	0x5400 6800

9.3.5.2 L4 Target Agent (L4 TA)

This section provides information on the L4 Target agent (TA) register module. Each of the registers within the module instance is described separately in [Table 9-153](#) to [Table 9-177](#).

[Table 9-153](#) to [Table 9-178](#) provide information on the L4 Target Agent having two supplementary registers OCP_CONTROL and OCP_STATUS

The TA register block consists of the status and control registers that can be used to configure the interfaces of the targets.

Table 9-153. CORE_TA Common Register Summary

Table 9-187. L4_TA_AGENT_CONTROL_L

Address Offset	0x020
Physical Address	See Table 9-153 to Table 9-178
Description	Enable error reporting
Type	RW
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
Reserved	SERROR_REP Reserved REQ_TIMEOUT Reserved OCP_RESET

Bits	Field Name	Description	Type	Reset
31:25	Reserved	Read returns 0.	R	0x00
24	SERROR_REP	Enable logging of error	R	0x0
23:11	Reserved	Read returns 0.		
10:8	REQ_TIMEOUT	Timeout Bound. Values are:0 - No timeout 1 - 1x base cycles 2 - 4x base cycles 3 - 16x base cycles 4 - 64x base cycles	RW	0x2
7:1	Reserved	Read returns 0.	R	0x00
0	OCP_RESET	The OCP_RESET field controls the OCP reset signal to the attached core. Setting this bit clears any pending transfers and resets the OCP interface. The bit must be cleared to de-assert the OCP reset signal. When the software reset feature is available on a target agent, the target agent OCP must also have a reset signal directed to the target core.	RW	0

9.3.5.3 L4 Link Register Agent (LA)

This section provides information on the L4-Core link agent (LA) register module. Each of the registers within the module instance is described separately in [Table 9-195](#).

The LA register block contains the initiator subsystem information register and the composite sideband signal mask and status registers.

Table 9-195. L4 LA Register Summary

Reserved		PROT_GROUPS		NUMBER_REGIONS				Reserved								SEGMENTS																																																	

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Read returns 0.	R	0x0
27:24	PROT_GROUPS	The number of protection groups. The PROT_GROUPS field contains read-only configuration information for the address mapping and protection structure of the initiator subsystem. If the PROT_GROUPS field is set to 0, there are no protection group registers.	R	see Table 9-206
23:16	NUMBER_REGIONS	The number of regions. The NUMBER_REGIONS field contains read-only configuration information for the region register of the initiator subsystem.	R	see Table 9-206
15:4	Reserved	Read returns 0.	R	0x000
3:0	SEGMENTS	The number of segments. The SEGMENT fields contains read-only configuration information for the segment register of the initiator subsystem.	R	see Table 9-206

NUMBER_REGIONS	0x64	0x2B	0x1A	0x13
SEGMENTS	0x6	0x5	0x3	0x2

Table 9-207. L4_LA_INITIATOR_INFO_H

Address Offset	0x01C
Physical Address	Please refer to Table 9-195
Description	Contain initiator subsystem information.
Type	R

Bits	Field Name	Description	Type	Reset
31:19	Reserved	Read returns 0.	R	0x0000
18:16	THREADS	The THREADS field specifies the number of initiator threads connected to the interconnect. The field contains read-only configuration information for the initiator subsystem.	R	see Table 9-209
15	Reserved	Read returns 0.	R	0
14:12	CONNID_WIDTH	The initiator subsystem connID width. The CONNID_WIDTH field contains read-only configuration information for the initiator subsystem.	R	see Table 9-209
11	Reserved	Read returns 0.	R	0
10:8	BYTE_DATA_WIDTH_EXP	This field specifies the initiator subsystem data width. 1:2^1 bytes specifies a 16-bit data width and 2:2^2 bytes specifies a 32-bit data width. The BYTE_DATA_WIDTH_EXP field contains read-only configuration information for the initiator subsystem.	R	see Table 9-209
7:5	Reserved	Read returns 0.	R	0x0
4:0	ADDR_WIDTH	This field specifies the initiator subsystem address width. The ADDR_WIDTH field contains read-only configuration information for the initiator subsystem.	R	see Table 9-209

ADDR_WIDTH	0x18	0x14	0x18	0x14

Table 9-210. L4_LA_NETWORK_CONTROL_L

Address Offset	0x020
Physical Address	Please refer to Table 9-195
Description	Control interconnect minimum timeout values.
Type	RW

Bits	Field Name	Description	Type	Reset
31:11	Reserved	Read returns 0.	R	0x000000
10:8	TIMEOUT_BASE	The TIMEOUT_BASE field indicates the timeout period (that is, base cycles) for the highest frequency time-base signal sent from the L4 initiator subsystem to all target agents that have timeout enabled. Values for the field are: 0 - Timeout disabled 1 - L4 interconnect clock cycles divided by 64 2 - L4 interconnect clock cycles divided by 256 3 - L4 interconnect clock cycles divided by 1024 4 - L4 interconnect clock cycles divided by 4096	RW	0x4
7:0	Reserved	Read returns 0.	R	0x00

Table 9-212. L4_LA_NETWORK_CONTROL_H

Address Offset	0x024
Physical Address	Please refer to Table 9-195
Description	Control interconnect global power control
Type	RW

Bits	Field Name	Description	Type	Reset
31:25	Reserved	Read returns 0.	R	0x00
24	CLOCK_GATE_DISABLE	When set to 1 this field disables all clock gating.	RW	0
23:21	Reserved	Read returns 0.	R	0x0
20	THREAD0_PRI	Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads.	R	1
19:9	Reserved	Read returns 0.	R	0x000
8	EXT_CLOCK	When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off.	R	1
7:0	Reserved	Read returns 0.	R	0x00

9.3.5.4 L4 Address Protection (AP)

This section provides information on the L4-Core link agent (LA) register module. Each of the registers within the module instance is described separately in [Table 9-214](#).

The AP register block contains the segment, address region, and protection group registers that can be used to specify the addressing scheme or restrict the access of target address regions.

Table 9-214. L4 AP Register Summary

Register Name	Type	Register Width (Bits)	CORE_AP Physical Address	PER_AP Physical Address

Memory Subsystem

This chapter describes the memory subsystem.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
10.1 General-Purpose Memory Controller	2120
10.2 SDRAM Controller (SDRC) Subsystem	2230
10.3 On-Chip Memory Subsystem	2339

10.1 General-Purpose Memory Controller

10.1.1 General-Purpose Memory Controller Overview

The general-purpose memory controller (GPMC) is the device unified memory controller (UMC) dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

Figure 10-1 shows the environment of the GPMC.

Figure 10-1. GPMC Environment

10.1.1.1 GPMC Features

The GPMC is the device 16-bit external memory controller. The GPMC data access engine provides a flexible programming model for communication with all standard memories. The GPMC supports various accesses:

- Asynchronous read/write access

- Asynchronous read page access (4, 8, 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8, 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8, 16 Word16)
- Address/data-multiplexed access
- Little- and big-endian access

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (non-burst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit nonmultiplexed device with limited address range (2 Kbytes)
- External 16-bit address/data-multiplexed NOR flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-static random access memory (pSRAM) device

The GPMC supports up to eight chip-select regions of programmable size, and programmable base addresses in a total address space of 1 Gbyte.

10.1.2 GPMC Environment

Figure 10-2 and Figure 10-3 show two GPMC external connection options:

- GPMC to 16-bit address/data-multiplexed memory

[Figure 10-2](#) shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed external memory device.

- GPMC to 16-bit NAND device

[Figure 10-3](#) shows a connection between the GPMC and a 16-bit NAND device.

Figure 10-2. GPMC to 16-Bit Address/Data-Multiplexed Memory

gpmc-002

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit-wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0] / gpmc_d[7:0] data bus (rather than D[15:8] / gpmc_d[15:8]) of the GPMC. This limits the use of 8-bit-wide device interfacing to byte-alias access.

Figure 10-3. GPMC to 16-Bit NAND Device

gpmc-003

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit-wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0]/gpmc_d[7:0] data bus (rather than D[15:8]/gpmc_d[15:8]) of the GPMC. This limits the use of 8-bit-wide device interfacing to byte-alias accesses.

Table 10-1 lists the GPMC subsystem I/O pins.

Table 10-1. GPMC I/O Description

Pin Name	I/O	Description
gpmc_a[11:1]	O	Address
gpmc_d[15:0]	I/O	Data
gpmc_ncs[7:0]	O	Chip-selects (active low)
gpmc_clk	I/O	Clock ⁽¹⁾
gpmc_nadv_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
gpmc_noe_nre	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
gpmc_nwe	O	Write enable (active low)
gpmc_nbe0_cle	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.

⁽¹⁾ This output signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

Table 10-1. GPMC I/O Description (continued)

Pin Name	I/O	Description
gpmc_nbe1	O	Byte 1 enable (active low)
gpmc_nwp	O	Write protect (active low)
gpmc_wait[3:0]	I	External wait signal for NOR and NAND protocol memories
gpmc_io_dir	O	gpmc_d[15:0] signal direction control: Low during transmit (for write access: data OUT from GPMC to memory), High during receive (for read access: data IN from memory to GPMC)

Table 10-2 shows the use of address and data GPMC pins based on the type of external device.

Table 10-2. GPMC Pin Multiplexing Options

GPMC Pin	Multiplexed Address Data 16-Bit Device	16-Bit NAND Device	8-Bit NAND Device
gpmc_a[11]	A27	Not used	Not used
gpmc_a[10]	A26	Not used	Not used
gpmc_a[9]	A25	Not used	Not used
gpmc_a[8]	A24	Not used	Not used
gpmc_a[7]	A23	Not used	Not used
gpmc_a[6]	A22	Not used	Not used
gpmc_a[5]	A21	Not used	Not used
gpmc_a[4]	A20	Not used	Not used
gpmc_a[3]	A19	Not used	Not used
gpmc_a[2]	A18	Not used	Not used
gpmc_a[1]	A17	Not used	Not used
gpmc_d[15]	A16/D15	D15	Not used
gpmc_d[14]	A15/D14	D14	Not used
gpmc_d[13]	A14/D13	D13	Not used
gpmc_d[12]	A13/D12	D12	Not used
gpmc_d[11]	A12/D11	D11	Not used
gpmc_d[10]	A11/D10	D10	Not used
gpmc_d[9]	A10/D9	D9	Not used
gpmc_d[8]	A9/D8	D8	Not used
gpmc_d[7]	A8/D7	D7	D7
gpmc_d[6]	A7/D6	D6	D6
gpmc_d[5]	A6/D5	D5	D5
gpmc_d[4]	A5/D4	D4	D4
gpmc_d[3]	A4/D3	D3	D3
gpmc_d[2]	A3/D2	D2	D2
gpmc_d[1]	A2/D1	D1	D1
gpmc_d[0]	A1/D0	D0	D0

Enabling the GPMC.GPMC_CONFIG[1] LIMITEDADDRESS bit forces A[26:11] to 1 on the GPMC I/O side. Thus, only devices with 2 Kbytes of addressing space can be accessed using gpmc_a[11:1].

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

- To minimize the number of IC pins required for the external memory connection, the NOR flash memory controller supports multiplexed address and data memory devices without adding logic externally.

- Multiplexing mode can be selected through the GPMC.GPMC_CONFIG1[i][9] MUXADDATA bit ($i = 0$ to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

10.1.3 GPMC Integration

10.1.3.1 Description

Figure 10-4 shows how the GPMC interacts with other modules in the device.

Figure 10-4. GPMC Integration in the Device

10.1.3.2 Clocking, Reset, and Power-Management Scheme

10.1.3.2.1 Clocking

The GPMC uses a single clock, GPMC_FCLK, which comes internally from the power, reset, and clock-management (PRCM) module and runs at the L3 interconnect frequency. Its source is the PRCM module, CORE_L3_ICLK output. CORE_L3_ICLK belongs to the L3 interconnect clock domain.

For details, see [Chapter 3, Power, Reset, and Clock Management](#).

GPMC_CLK is the external clock provided to the attached synchronous memory or device. The GPMC_CLK clock frequency is the GPMC_FCLK clock frequency divided by 1, 2, 3, or 4, depending on the GPMC.[GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER bit field (where i = 0 to 7).

NOTE: When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL_PADCONF_GPMC_NCS7[24] INPUTENABLE1 = 1). GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at the device boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

10.1.3.2.2 Hardware Reset

A global reset of the GPMC occurs through activation of the CORE_RSTRET signal (CORE power domain) controlled by the PRCM module (see [Chapter 3, Power, Reset, and Clock Management](#)). The CORE_RSTRET signal is activated during IC global power-on and global warm reset, and it resets the controller state machine and configuration registers.

10.1.3.2.3 Software Reset

GPMC modules can be reset under software control through the GPMC.[GPMC_SYSConfig\[1\]](#) SOFTRESET bit. When software reset bit is set, all registers and the finite state-machine (FSM) are reset immediately and unconditionally. The GPMC.[SYSSTATUS\[0\]](#) RESETDONE bit can be polled to check reset status.

10.1.3.2.4 Power Domain, Power Saving, and Reset Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

The GPMC reduces power consumption through auto-idle mode and the idle request/acknowledge process, both of which are configurable:

- Dynamic auto-idle (configurable through the GPMC.[GPMC_SYSConfig\[0\]](#) AUTOIDLE bit): To reduce power consumption, the GPMC internally disables the functional clock when no requests are pending and no accesses are ongoing.
- Idle request/acknowledge (one of three idle modes configurable through the GPMC.[GPMC_SYSConfig\[4:3\]](#) IDLEMODE field):
 - Force-idle: Immediately on receiving an idle request from the PRCM module, the GPMC sends an idle request/acknowledge to let the PRCM module correctly cut the GPMC source clock.
 - No-idle: The GPMC never goes to idle mode.
 - Smart-idle (strongly recommended): The GPMC goes to idle mode when all ongoing transactions are complete.

For detailed information about power management, see [Chapter 3, Power, Reset, and Clock Management](#).

10.1.3.2.5 Hardware Requests

The GPMC uses two hardware requests as shown in [Figure 10-4](#):

- One interrupt request goes from GPMC (GPMC_IRQ) to the microprocessor unit (MPU) subsystem : M_IRQ_20.
- One DMA request goes from GPMC (GPMC_DMA_REQ) to the system DMA (sDMA) : S_DMA_3.

10.1.3.3 GPMC Address and Data Bus

The current application supports GPMC connection to address/data-multiplexed memory and a NAND device. Connection to a nonmultiplexed address/data memory is supported with an address range of only 2 Kbytes.

Depending on the GPMC configuration on each chip-select, address and data-bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

The current application supports GPMC connection to address/data-multiplexed memory, address/data-nonmultiplexed memory with limited address (2 Kbytes), and a NAND device:

- When the GPMC.[GPMC_CONFIG\[1\]](#) LIMITEDADDRESS bit is set to 1, only gpmc_a[11:1] address lines are used. This limits the memory support to 2K-byte addressable memories.
- For address/data-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: gpmc_d[15:8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: gpmc_a[11:1] .
- 8-bit wide NAND devices do not use GPMC I/O: gpmc_a[11:1] and GPMC I/O: gpmc_d[15:8].

CAUTION

Before trying to access a chip-select configured with a nonmultiplexed protocol, set the LIMITEDADDRESS bit control.

10.1.3.3.1 GPMC I/O Configuration Setting (in Default Pinout Mode 0)

NOTE: In this section, the i in [GPMC_CONFIG1_i](#) stands for the GPMC chip-select i where i = 0 to 7.

The address/data-nonmultiplexed device, which is limited to a 2K-byte address range, is selected by programming the following register fields:

- GPMC.[GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field = 0x00
- GPMC.[GPMC_CONFIG1_i\[9\]](#) MUXADDDATA bit = 0
- GPMC.[GPMC_CONFIG\[1\]](#) LIMITEDADDRESS bit = 1

NOTE: The LIMITEDADDRESS field applies only to address/data-nonmultiplexed devices; it has no effect on other device types (address/data-multiplexed, NAND).

To select the address/data-multiplexed device, program the following register fields:

- GPMC.[GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field = 0b00
- GPMC.[GPMC_CONFIG1_i\[9\]](#) MUXADDDATA bit = 1

To select the NAND device, program the following register field:

- GPMC.[GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field = 0b10
- GPMC.[GPMC_CONFIG1_i\[9\]](#) MUXADDDATA bit = 0

10.1.3.3.2 GPMC CS0 Default Configuration at IC Reset

To ensure a correct external boot with a GPMC access from IC reset time on CS0, several external pins are sampled:

- The sys_boot[4:0] pins (device boundary) define the sequence of interfaces and devices to use for booting.
- The sys_boot[5] pin defines which group of booting sequences is preferred: memory booting (sys_boot[5] = 0) or peripheral booting (sys_boot[5] = 1).
- Three additional pins are used to configure reset values in the GPMC.[GPMC_CONFIG1_i](#) register (where i = 0):
 - The bootwaitein input pin (GPMC boundary) enables the monitoring on chip-select 0 of the WAIT pin at IC reset release time for read accesses. The input pin is used to configure the GPMC.[GPMC_CONFIG1_i](#)[22] WAITREADMONITORING bit (where i = 0). Its value comes from the BOOT_WAIT_ENABLE signal generated by the system control module (SCM). When sys_boot[5:0] = 0b111111, the BOOT_WAIT_ENABLE signal is activated, causing the wait pin to be monitored for read access.
 - The bootdevicesize input pin (GPMC boundary) defines the size of the attached device on chip-select 0 and is used to configure the GPMC.[GPMC_CONFIG1_i](#)[13:12] DEVICESIZE bits (where i = 0). A BOOT_DEVICE_SIZE signal is propagated from the SCM. Its value is fixed at 0x1 at IC reset, causing a 16-bit wide external memory to be used.
 - The cs0muxdevice input pin (GPMC boundary) selects whether the attached device to chip-select 0 is a multiplexed address and data device or not. The input pin is used to configure the GPMC.[GPMC_CONFIG1_i](#)[9] MUXADDDATA bit (where i = 0). A CS0_MUX_DEVICE signal is propagated from the SCM. Its value is fixed at 0x1 at IC reset, causing the attached device to be address/data-multiplexed.
 - The waitselectpin input pin selects the WAIT signal at IC reset release time between WAIT0 input pin or WAIT1 input pin. At IC reset release time, these two pins have different polarity.

CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed 2-Kbyte address range device attached to CS0

At reset time, the IC may boot from the internal ROM or from the memory attached to the GPMC chip-select 0. This selection is made outside the GPMC.

Reset values of the timing control parameters are defined to cope with direct boot on address and data multiplexed NOR Flash device, on non-multiplexed NOR Flash device or on any asynchronous device with large timing margins assuming a low GPMC_FCLK frequency (for example, 19.2Mhz) at boot time.

10.1.4 GPMC Functional Description

10.1.4.1 Description

As [Figure 10-5](#) shows, the GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 10-5. GPMC Functional Diagram

gpmc-005

The GPMC can access various external devices through the L3 Interconnect. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

10.1.4.2 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including an 8 * 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-bit/16-bit/32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts $2 * 32$, $4 * 32$, or $8 * 32$ with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the ATTACHEDDEVICEPAGELENGTH field ([GPMC_CONFIG1_i\[24:23\]](#)) according to the effective attached device page length and to enable WRAPBURST bit ([GPMC_CONFIG1_i\[31\]](#)) if the attached device supports wrapping burst.

However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

10.1.4.3 Address Decoder, GPMC Configuration, and Chip-Select Configuration Register File

Address-decoding logic selects for chip-selects according to the address request and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). [Section 10.1.7](#) of this chapter provides the GPMC register locations. For the map of GPMC memory locations, see [Chapter 2, Memory Mapping](#).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

10.1.4.4 Error Correction Code Engine

The GPMC includes an error correction code (ECC) calculation engine that allows ECC calculation during data read or data program (write) operations. Two ECC algorithms are available depending on [GPMC_ECC_CONFIG\[16\]](#) ECCALGORITHM settings: Hamming code or BCH code (Bose-Chaudhuri-Hocquenghem).

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or Word16s read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC [GPMC_ECC_CONFIG\[3:1\]](#) ECCCS bit field.

See [Section 10.1.5.14.3](#) for more information on ECC calculation.

10.1.4.5 Prefetch and Write-Posting Engine

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

For more information about prefetch and write-posting engine programming, see [Section 10.1.5.14.4, Prefetch and Write-Posting Engine](#).

10.1.4.6 External Device/Memory Port Interface

The external port interface controls all address, data, and control signals required for communication with GPMC-supported devices and memories.

10.1.5 GPMC Basic Programming Model

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, Word16, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit-wide devices are supported only in single-synchronous or asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

10.1.5.1 Chip-Select Base Address and Region Size Configuration

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 1-GB contiguous address space. For details, see [Chapter 2 Memory Mapping](#).

The GPMC 1-GB address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16MB to 256MB (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in [Figure 10-6](#) (with A0 as the device system byte-address line). Base address is programmed through the [GPMC_CONFIG7_i\[5:0\] BASEADDRESS](#) bit field
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the [GPMC_CONFIG7_i\[11:8\] MASKADDRESS](#) bit field.

Figure 10-6. Chip-Select Address Mapping and Decoding Mask

NOTE: GPMC can address up to 256MB on cs0 and cs1, support 128MB on cs2 to cs7

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC.[GPMC_CONFIG7_i\[6\] CSVVALID](#) bit (where i stands for the GPMC chip-select value, i = 0 to 7). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Conversely, before trying to access a chip-select, software must ensure that the chip-select is enabled. To account for prefetch engine effects, after the chip-select-enable instruction, an NOP instruction (equivalent to 64 bits) must be executed before the chip-select is accessed.

Any access attempted to a nonvalid GPMC address region (CSVVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select.

Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

CAUTION

Although the GPMC interface can drive up to 8 chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached.

10.1.5.2 Access Protocol Configuration**10.1.5.2.1 Supported Devices**

The access protocol of each chip-select can be independently specified through the GPMC.[GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE parameter (where i = 0 to 7) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

NOTE: NAND flash interfacing requires the parameter settings of generic chip-select 0. For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 10.1.5.14, NAND Device Basic Programming Model](#), and [Section 10.1.5.14.1, NAND Memory Device in Byte or Word 16 Stream Mode](#).

10.1.5.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC.[GPMC_CONFIG1_i\[13:12\]](#) DEVICESIZE field (i = 0 to 7) to interface with a 16-bit wide device or an 8-bit-wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit-wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit-wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

10.1.5.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC.[GPMC_CONFIG1_i\[9\]](#) MUXADDDATA bit (i = 0 to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See [Section 10.1.3, GPMC Integration](#).

NOTE: This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol. See [Section 10.1.5.14, NAND Device Basic Programming Model](#).

10.1.5.2.4 Address and Data Bus

See [Section 10.1.3.3, GPMC Address and Data Bus](#).

10.1.5.2.5 Asynchronous and Synchronous Access

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the GPMC.[GPMC_CONFIG1_i\[29\]](#) READTYPE bit (i = 0 to 7). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the GPMC.[GPMC_CONFIG1_i\[27\]](#) WRITETYPE bit (i = 0 to 7).

Asynchronous and synchronous read (write) access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

NOTE: The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

10.1.5.2.6 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The [GPMC_CONFIG1_I\[30\]](#) READMULTIPLE and [GPMC_CONFIG1_I\[28\]](#) WRITMULTIPLE bits ($i = 0$ to 7) are associated with the READTYPE and WRITETYPE parameters.

NOTE:

- Asynchronous write page mode is not supported.
 - 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITMULTIPLE are don't care).
 - Not applicable to NAND device interfacing.
-

10.1.5.2.7 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, Word16, Word32 requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the [GPMC_CONFIG1_I\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH field ($i = 0$ to 7). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple burst beats. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the [GPMC_CONFIG1_I\[31\]](#) WRAPBURST bit ($i = 0$ to 7) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPCM behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst beat.

NOTE: When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

10.1.5.3 Timing Setting

The GPMC is a signal generator that offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For example, the timing diagram in Figure 10-7 shows an asynchronous single-read access performed on an asynchronous device. For more information about GPMC_CLK and GPMC_FCLK, see [Section 10.1.5.3.6](#).

Figure 10-7. Asynchronous Single Read on a Nonmultiplexed Address/Data Device

10.1.5.3.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME/WRCYCLETIME)

The GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME and GPMC.GPMC_CONFIG5_i[12:8] WRCYCLETIME fields ($i = 0$ to 7) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle.

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (NCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitchy transition. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

If no inactive cycles are required between successive accesses to the same or to a different chip-select (GPMC.GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC.GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where $i = 0$ to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1, the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY:

- The RDCYCLETIME and WRCYCLETIME bit fields are programmable in the GPMC.[GPMC_CONFIG5_i](#) register, i = 0 to 7.
- The RDCYCLETIME and WRCYCLETIME bit fields can be set from 0 to 31 GPMC_FCLK cycles with a granularity of 1 for GPMC.[GPMC_CONFIG1_i\[4\]](#) TIMEPARAGRANULARITY set to 0.
- The RDCYCLETIME and WRCYCLETIME bit fields can be set from 0 to 62 GPMC_FCLK cycles with a granularity of 2 for GPMC.[GPMC_CONFIG1_i\[4\]](#) TIMEPARAGRANULARITY set to 1.

10.1.5.3.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME/CSRDOFFTIME/CSWROFFTIME/CSEXTRADELAY)

The GPMC.[GPMC_CONFIG2_i\[3:0\]](#) CSONTIME field (where i = 0 to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

For a read access, the GPMC.[GPMC_CONFIG2_i\[12:8\]](#) CSRDOFFTIME field defines the nCS signal deassertion time relative to start access time.

For a write access, the GPMC.[GPMC_CONFIG2_i\[20:16\]](#) CSWROFFTIME field defines the nCS signal deassertion time relative to start access time.\

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

nCS signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.[GPMC_CONFIG2_i\[7\]](#) CSEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If asserted, CSEXTRADELAY applies to all parameters controlling nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

10.1.5.3.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME/ADVRDOFFTIME/ADVWROFFTIME/ADVEXTRADELAY)

The GPMC.[GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field (where i = 0 to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

For a read access, the GPMC.[GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME field defines the nADV/ALE signal-deassertion time relative to start access time.

For a write access, the GPMC.[GPMC_CONFIG3_i\[20:16\]](#) ADVWROFFTIME field defines the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after nADV/ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.[GPMC_CONFIG3_i\[7\]](#) ADVEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If asserted, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

See [Section 10.1.5.14](#) for more details about ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME use for command (CLE) and address latch enable (ALE) use for a NAND flash interface.

10.1.5.3.4 *nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME/OEOFETIME/OEEXTRADELAY)*

The GPMC.[GPMC_CONFIG4_i](#)[3:0] OEONTIME field (where i = 0 to 7) defines the nOE/nRE signal assertion time relative to start access time. It is applicable only to read accesses.

The GPMC.[GPMC_CONFIG4_i](#)[12:8] OEOFETIME field defines the nOE/nRE signal deassertion time relative to start access time. It is applicable only to read accesses.

OEONTIME and OEOFETIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFETIME can be used to control an address and byte enable valid hold time control after nOE/nRE assertion.

The nOE/RE signal transitions as controlled through OEONTIME, and OEOFETIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.[GPMC_CONFIG4_i](#)[7] OEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nOE/RE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If asserted, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

nOE/nRE is not asserted during a write cycle.

NOTE: When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

10.1.5.3.5 *nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME/WEOFETIME/WEEXTRADELAY)*

The GPMC.[GPMC_CONFIG4_i](#)[19:16] WEONTIME field (where i = 0 to 7) defines the nWE signal-assertion time relative to start access time. It applies only to write accesses.

The GPMC.[GPMC_CONFIG4_i](#)[28:24] WEOFETIME field defines the nWE signal-deassertion time relative to start access time. It applies only to write accesses.

WEONTIME can be used to control an address and byte enable valid setup time control before nWE assertion. WEOFETIME can be used to control an address and byte enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFETIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.[GPMC_CONFIG4_i](#)[23] WEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If asserted, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

nWE is not asserted during a read cycle.

10.1.5.3.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC.GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where $i = 0$ to 7), with a guaranteed 50-percent duty cycle.
- The GPMC_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC.GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field ($i = 0$ to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.
- When cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.
- When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL_PADCONF_GPMC_NCS7[24] INPUTENABLE1 = 1). GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at the device boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

NOTE: To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME – CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

10.1.5.3.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC.GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field ($i = 0$ to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by half of a GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEEXTRADELAY, or WEEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

10.1.5.3.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently allowing nOE and GPMC data capture timing parameters to be independent of nWE and memory device data capture timing parameters.

RDACCESSTIME is programmed in the GPMC.GPMC_CONFIG5_i[20:16] bit field ($i = 0$ to 7).

WRACCESSTIME is programmed in the GPMC.GPMC_CONFIG6_i[28:24] bit field ($i = 0$ to 7).

RDACCESSTIME and WRACCESSTIME can be set from 0 to 31 GPMC_FCLK cycles with a granularity of one (GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY = 0).

RDACCESSTIME and WRACCESSTIME can be set from 0 to 62 GPMC_FCLK cycles with a granularity of two (GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY = 1).

10.1.5.3.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, RDACCESSTIME field ($i = 0$ to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater GPMC_FCLK cycle value of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK which is sent to the memory device for synchronization with the GPMC, is internally retimed to correctly latch the returned data. RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see [Section 10.1.5.4](#).

10.1.5.3.8.2 Access Time on Write Access

In asynchronous write mode, the [GPMC_CONFIG6_i\[28:24\]](#) WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see [Section 10.1.5.4](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC_CLK edge for a synchronous write access. For details about wait monitoring, see [Section 10.1.5.4](#).

10.1.5.3.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

PAGEBURSTACCESSTIME is programmed in the GPMC.[GPMC_CONFIG5_i\[27:24\]](#) bit field ($i = 0$ to 7). PAGEBURSTACCESSTIME can be set from 0 to 15 GPMC_FCLK cycles with a granularity of one (GPMC.[GPMC_CONFIG1_i\[4\]](#) TIMEPARAGRANULARITY set to 0), or from 0 to 30 GPMC_FCLK cycles with a granularity of two (TIMEPARAGRANULARITY set to 1).

10.1.5.3.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater GPMC_FCLK cycle value of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC_FCLK edge on read access. For details about wait monitoring, see [Section 10.1.5.4](#).

10.1.5.3.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC_CLK edge in synchronous write mode. For details about wait monitoring, see [Section 10.1.5.4](#).

10.1.5.3.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDACYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

10.1.5.4 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC four input wait pins: gpmc_wait3, gpmc_wait2, gpmc_wait1, and gpmc_wait0. These four pins allow direct plugin and control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC.[GPMC_CONFIG1_i\[17:16\]](#) WAITPINSELECT field ($i = 0$ to 7) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC.[GPMC_CONFIG](#) register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured by CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC.[GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC.[GPMC_CONFIG1_i\[21\]](#) WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC.[GPMC_CONFIG1_i\[29\]](#) READTYPE and GPMC.[GPMC_CONFIG1_i\[27\]](#) WRITETYPE bits).

10.1.5.4.1 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.

- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC.GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME field ($i = 0$ to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 10-8 shows wait behavior during an asynchronous single read access.

Figure 10-8. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)

NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

10.1.5.4.2 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (GPMC.GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 0x1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC.GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME fields (i = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
 - This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as synchronous, and even though no clock is provided to the external device. Still, GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.
-

10.1.5.4.3 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC.GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME field (where i = 0 to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC.GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME /= 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.

- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 10-9 shows wait behavior during a synchronous read burst access.

Figure 10-9. Wait Behavior During a Synchronous Read Burst Access

NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

10.1.5.4.4 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to control the effective memory device GPMC_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- The WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME /= 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

NOTE: Wait monitoring is supported for all configurations except for [GPMC_CONFIG1_i\[19:18\]](#) WAITMONITORINGTIME = 0x 0 (where i = 0 to 7) for write bursts with a clock divider of 1 or 2 ([GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER bit field equal to 0x0 or 0x1, respectively).

10.1.5.4.5 WAIT With NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see [Section 10.1.5.14.2, NAND Device-Ready Pin](#).

10.1.5.4.6 Idle Cycle Control Between Successive Accesses

10.1.5.4.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device (that is, control the nCS/nOE de-assertion to data bus in high-impedance delay) must be delayed.

The bus turnaround is a time-out counter starting after nCS or nOE de-assertion time (whichever occurs first) and delays the next access start-cycle time. It is programmed through the [GPMC.GPMC_CONFIG6_i\[3:0\] BUSTURNAROUND](#) bit field (where i = 0 to 7).

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

10.1.5.4.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The [GPMC.GPMC_CONFIG6_i\[7\] CYCLE2CYCLESAMECSEN](#) bit (i = 0 to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the [GPMC.GPMC_CONFIG6_i\[11:8\] CYCLE2CYCLEDELAY](#) field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during Word32 or burst accesses split into successive single accesses when the single-access mode is used ([GPMC_CONFIG1_i\[30\]](#) READMULTIPLE = 0 or [GPMC_CONFIG1_i\[28\]](#) WRITEMULTIPLE = 0).

All control signals are kept in their default states during these idle GPMC_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

10.1.5.4.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If [GPMC_CONFIG6_i\[6\]](#) CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

NOTE: CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in the [GPMC_CONFIG6_i](#) registers to insert idle cycles between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on the access type combination, since bus turnaround does not apply to all access types. See [Section 10.1.5.4.6.1](#) for more details on bus turnaround.

[Table 10-3](#) describes the configuration required for idle cycle insertion.

Table 10-3. Idle Cycle Insertion Configuration

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BTA cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BTA cycles are inserted.
R	> 0	W	Any	Any	0	0	BTA cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.

Table 10-3. Idle Cycle Insertion Configuration (continued)

1st Access Type	BUSTURNAROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

10.1.5.4.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC.GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select value, i = 0 to 7). Increasing all access timing parameters allows support of slow devices.

10.1.5.5 gpmc_io_dir Pin

The gpmc_io_dir pin is used to control I/O direction on the GPMC data bus gpmc_d[15:0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the device, if required.

The gpmc_io_dir pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the gpmc_io_dir pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the gpmc_io_dir pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled:
 - The gpmc_io_dir pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled:
 - After an asynchronous read access, the gpmc_io_dir pin goes from IN to OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
 - After a synchronous read access, the gpmc_io_dir pin goes from IN to OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the gpmc_io_dir pin is OUT (see [Section 10.1.5.3.10, Bus Keeping Support](#)).

To prevent unnecessary toggling, the gpmc_io_dir pin stays IN between two successive read accesses to a nonmultiplexed device (address mapping supports nonmultiplexed 16-bit wide devices with limited address (2 Kbytes)).

[Figure 10-10](#) shows address mapping in nonmultiplexed mode with a limited address range (A[10:1]).

10.1.5.6 Reset

No reset signal is sent to the external memory device by the GPMC. For more information see [Chapter 3, Power, Reset, and Clock Management](#).

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during device warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

10.1.5.7 WRITE PROTECT (nWP)

When connected to the attached memory device, the WRITE PROTECT signal can enable or disable the lockdown function of the attached memory.

The gpmc_nwp output pin value is controlled through the GPMC.GPMC_CONFIG[4] WRITEPROTECT bit, which is common to all CS.

10.1.5.8 BYTE ENABLE (nBE1/nBE0)

BYTE ENABLE signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

10.1.5.9 Asynchronous Access Description

In asynchronous operations:

- GPMC_CLK is not provided outside the GPMC.
- GPMC_CLK is kept low.

10.1.5.9.1 Asynchronous Single Read

10.1.5.9.1.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

Figure 10-10 shows an asynchronous single read operation on a nonmultiplexed device.

Figure 10-10. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device

gpmc-010

In the following section i stands for the chip-select number, i = 0 to 7.

- GPMC.GPMC_CONFIG[1] LIMITEDADDRESS set to 1 (A26-A11 are not modified during an external memory access)
- GPMC.GPMC_CONFIG1_i register settings:
 - GPMC_CONFIG1_i[30] READMULTIPLE bit at 0 (read single access)
 - GPMC_CONFIG1_i[29] READTYPE bit at 0 (asynchronous read)
 - GPMC_CONFIG1_i[9] MUXADDDATA bit at 0 (non multiplexed device)
- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME field. It controls the address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME field.
 - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFETIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC.GPMC_CONFIG5_i[20:16] RDACCESSTIME field.
- The end of the access is defined by the RDCYCLETIME parameter. The read cycle time is defined in the GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 10.1.5.3.10, Bus Keeping Support](#) for more details.

10.1.5.9.1.2 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

[Figure 10-11](#) shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 10-11. Asynchronous Single Read on an Address/Data-Multiplexed Device

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see [Section 10.1.5.2.3, Address/Data-Multiplexing Interface](#).

GPMC.[GPMC_CONFIG1_i](#) register settings ($i = 0$ to 7):

- READMULTIPLE bit at 0 (read single access)
- READTYPE bit at 0 (read asynchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits ([16:1] from a GPMC perspective, [15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits [25:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as nonmultiplexed accesses.

10.1.5.9.2 Asynchronous Single Write

10.1.5.9.2.1 Asynchronous Single Write Operation on a Nonmultiplexed Device

Figure 10-12 shows an asynchronous single write operation on a nonmultiplexed device.

Figure 10-12. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device

gpmc-012

In the following section i stands for the chip-select number, $i = 0$ to 7.

- GPMC.GPMC_CONFIG[1] LIMITEDADDRESS set to 1 (A26-A11 are not modified during an external memory access)
- GPMC.GPMC_CONFIG1_i register settings:
 - WRITEMULTIPLE bit at 0 (write single access)
 - WRITETYPE bit at 0 (write asynchronous)
 - MUXADDDATA bit at 0 (nonaddress/data-multiplexed device)
- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_i[20:16] CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[20:16] ADVWROFFTIME field.

Address and data are driven on their corresponding buses at start-of-cycle time.

- Write enable signal nWE:
 - nWE assertion indicates a write cycle.
 - nWE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[19:16] WEONTIME field.
 - nWE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[28:24] WEOFFTIME field.
- Direction signal DIR:

DIR signal is OUT during the entire access.

- The end of the access is defined by the WRCYCLETIME parameter.

This write-cycle time is defined in the GPMC.GPMC_CONFIG5_i[12:8] WRCYCLETIME field.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 10.1.5.3.10, Bus Keeping Support](#).

In the GPMC, when a 16-bit wide device is attached to the controller, a Word32 write access is split into two Word16 write accesses. For more information about GPMC access size and type adaptation, see [Section 10.1.5.2.7, System Burst Versus External Device Burst Support](#).

Between two successive accesses, if an nCS pulse is needed:

- The GPMC.GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY field can be programmed with GPMC.GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

10.1.5.9.2.2 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

[Figure 10-13](#) shows an asynchronous single write operation on an address/data-multiplexed device.

Figure 10-13. Asynchronous Single Write on an Address/Data-Multiplexed Device

gpmc-013

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address on the address/data muxed bus until WRDATAONADMUXBUS time, and then it drives the data. For more information, see [Section 10.1.5.2.3, Address/Data-Multiplexing Interface](#).

GPMC.GPMC_CONFIG1_i register settings (i = 0 to 7):

- WRITEMULTIPLE bit at 0 (write single access)
- WRITETYPE bit at 0 (write asynchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits [16:1] are placed on the address/data bus at the start of cycle time, and the remaining address bits [26:17] are placed on the address bus.

The nCS, nADV, and nWE signals are controlled in the same way as nonmultiplexed accesses.

Data is driven on the address/data bus at a **GPMC_CONFIG6_i[19:16]** WRDATAONADMUXBUS time.

NOTE: Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

10.1.5.9.3 Asynchronous Multiple (Page Mode) Read

Figure 10-14 shows an asynchronous multiple read operation.

Figure 10-14. Asynchronous Multiple (Page Mode) Read

NOTE: The WAIT signal is active low.

In the following section i stands for the chip-select number, i = 0 to 7.

For read access with GPMC.GPMC_CONFIG1_i register settings:

- READMULTIPLE bit at 1 (read multiple access)
- READTYPE bit at 0 (read asynchronous)
- MUXADDDATA bit at 0 (non-address/data-multiplexed device). The page mode is not supported by address/data-multiplexed devices.

In [Figure 10-14](#), two Word32 read host accesses on the GPMC configured with READMULTIPLE = 1, READTYPE = 0, and MUXADDDATA = 0 are merged into one multiple-read access (page mode of four Word16) on the attached device.

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.[GPMC_CONFIG2_i\[3:0\]](#) CSONTIME field and ensures the address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC.[GPMC_CONFIG2_i\[12:8\]](#) CSRDOFFTIME field and ensures the address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.[GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.[GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC.[GPMC_CONFIG4_i\[3:0\]](#) OEONTIME field.
 - nOE deassertion time is controlled by the GPMC.[GPMC_CONFIG4_i\[12:8\]](#) OEOFETIME field.
- Initial latency for the first read data is controlled by the RDACCESSTIME parameter.
The access time is defined in the GPMC.[GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME field.

During consecutive accesses, the GPMC increments the address after each data read completes.

- Delay between successive read data in the page is controlled by the PAGEBURSTACCESSTIME parameter:
 - This timing is defined in the GPMC.[GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME field.
 - Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.
- Total access time (RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time starting from the nCS deassertion plus the time from RDACCESSTIME to CSRDOFFTIME.
 - The read cycle time is defined in the GPMC.[GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME field.
 - In [Figure 10-14](#), the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).
- Direction signal DIR:
DIR goes from OUT to IN at the same time as nOE assertion time.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 10.1.5.3.10, Bus Keeping Support](#).

10.1.5.10 Synchronous Access

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC.[GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER field (where i = 0 to 7).
- The GPMC.[GPMC_CONFIG1_i\[26:25\]](#) CLKACTIVATIONTIME field specifies that the GPMC_CLK is provided outside the GPMC 0, 1, or 2 GPMC_FCLK cycles after start access time until CycleTime completes.
- When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL_PADCONF_GPMC_NCS7[24] INPUTENABLE1 = 1). GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at device boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

10.1.5.10.1 Synchronous Single Read

Figure 10-15 and Figure 10-16 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 10-15. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

gpmc-015

Figure 10-16. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

gpmc-016

In the following section i stands for the chip-select number, i = 0 to 7.

- GPMC.[GPMC_CONFIG1_i](#) register settings:
 - READMULTIPLE bit at 0 (read single access)
 - READTYPE bit at 1 (read synchronous)
 - MUXADDDATA bit at 0 (non-address/data-multiplexed device)
- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.[GPMC_CONFIG2_i\[3:0\]](#) CSONTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC.[GPMC_CONFIG2_i\[12:8\]](#) CSROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.[GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.[GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC.[GPMC_CONFIG4_i\[3:0\]](#) OEONTIME field.
 - nOE deassertion time is controlled by the GPMC.[GPMC_CONFIG4_i\[12:8\]](#) OEOFETIME field.
- Initial latency for the first read data is controlled by GPMC.[GPMC_CONFIG5_i\[20:16\]](#)

RDACCESSTIME or by monitoring the WAIT signal.

- Total access time (GPMC.GPMC_CONFIG5_i[4:0] RD CYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSWROFFTIME.
- Direction signal DIR:
DIR goes from OUT to IN at the same time as nOE assertion.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 10.1.5.3.10, Bus Keeping Support](#).

10.1.5.10.2 Synchronous Single Write

Figure 10-17. Synchronous Single Write on an Address/Data-Multiplexed Device

NOTE: The WAIT signal is active low.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus until WRDATAONADMUXBUS time (GPMC_CONFIG6_i[19:16]).

The GPMC.GPMC_CONFIG1_i register settings ($i = 0$ to 7) are as follows:

- WRITEMULTIPLE bit at 0 (write single access)
- WRITETYPE bit at 1 (write synchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits [16:1] are placed on the address/data bus at cycle-start time, and the remaining address bits [26:17] are placed on the address bus.

The address phase ends at WRDATAONADMUXBUS.

The nCS, nADV, and nWE signals are controlled in the same way as nonmultiplexed accesses.

First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

10.1.5.10.3 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

Figure 10-18 and Figure 10-19 show a synchronous multiple read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 10-18. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

gpmc-018

NOTE: The WAIT signal is active low.

Figure 10-19. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

NOTE: The WAIT signal is active low.

In the following section i stands for the chip-select number, i = 0 to 7.

- GPMC.GPMC_CONFIG1_i register settings:
 - READMULTIPLE bit at 1 (read multiple access)
 - READTYPE bit at 1 (read synchronous)
 - MUXADDDATA bit at 0 (nonaddress/data-multiplexed device)

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSORTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_i[12:8] CSRDOFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[3:0] OEONTIME field.
 - nOE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[12:8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC.GPMC_CONFIG5_i[20:16] RDACCESSTIME or by monitoring the WAIT signal.
- Successive read data are provided by the memory device each one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the

memory-device internal configuration.

Depending on the device page length, the GPMC can control device page crossing during a new burst request and purposely insert initial latency.

- Total access time (RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus the time from RDACCESSTIME to CSRDOFFTIME.
 - RDCYCLETIME is defined in the GPMC.GPMC_CONFIG5_i register.
 - In [Figure 10-19](#), the RDCYCLETIME programmed value equals RDCYCLETIME0 + RDCYCLETIME1.
- Direction signal DIR:
DIR goes from OUT to IN at the same time as nOE assertion.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 10.1.5.3.10, Bus Keeping Support](#).

- Burst wraparound

The GPMC.GPMC_CONFIG1_i[31] WRAPBURST bit allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary.

10.1.5.10.4 Synchronous Multiple (Burst) Write

Burst write mode provides synchronous single or consecutive accesses.

[Figure 10-20](#) shows a synchronous multiple (burst) write.

Figure 10-20. Synchronous Multiple (Burst) Write

NOTE: The WAIT signal is active low.

In the following section i stands for the chip-select number, i = 0 to 7.

- GPMC.[GPMC_CONFIG1_i](#) register settings:
 - WRITEMULTIPLE bit at 1 (write multiple access)
 - WRITETYPE bit at 1 (write synchronous)
 - MUXADDDATA bit at 1 (address/data-multiplexed device)

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.[GPMC_CONFIG2_i\[3:0\]](#) CSONTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time controlled by the GPMC.[GPMC_CONFIG2_i\[20:16\]](#) CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.[GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.[GPMC_CONFIG3_i\[20:16\]](#) ADVWROFFTIME field.
- Write enable signal nWE:

- nWE assertion indicates a write cycle.
- nWE assertion time is controlled by the GPMC.[GPMC_CONFIG4_i\[19:16\]](#) WEONTIME field.
- nWE deassertion time is controlled by the GPMC.[GPMC_CONFIG4_i\[28:24\]](#) WEOFFTIME field.

NOTE: The nWE falling edge must not be used to control the time when the burst first data is driven in the address / data bus because some new devices require the nWE signal at low during the address phase.

- First write data is driven by the GPMC at WRDATAONADMUXBUS ([GPMC_CONFIG6_i\[19:16\]](#)), when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until WRCYCLETIME completes.
 - WRACCESSTIME is defined in the GPMC.[GPMC_CONFIG5_i](#) register.
 - The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.
- Total access time (WRCYCLETIME) corresponds to WRACCESSTIME plus the address hold time from nCS deassertion, plus time from WRACCESSTIME to CSWROFFTIME.
 - WRCYCLETIME is defined in the GPMC.[GPMC_CONFIG5_i](#) register.
 - In [Figure 10-20](#), the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1.
- Direction signal DIR:
DIR is OUT during the entire access.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 10.1.5.3.10, Bus Keeping Support](#).

[Figure 10-21](#) shows the same synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 10-21. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

The first data of the burst is driven on the a/d bus at [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS.

10.1.5.11 pSRAM Basic Programming Model

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. These devices can be accessed by the GPMC with the GPMC.[GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field ($i = 0$ to 7).

The pSRAM devices support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

In both pSRAM cases, the GPMC configuration for this chip-select must be set according to the specifications of the attached device.

10.1.5.12 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC.[GPMC_ERR_TYPE](#) register and the address of the illegal access is stored in the GPMC.[GPMC_ERR_ADDRESS](#) register. The GPMC only keeps the first error abort information until the GPMC.[GPMC_ERR_TYPE](#) register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC.[GPMC_ERR_TYPE](#)[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1 Kbyte.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC.[GPMC_TIMEOUT_CONTROL](#) register and enabled with the GPMC.[GPMC_TIMEOUT_CONTROL](#)[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

10.1.5.13 Boot Configuration

See [Section 10.1.3.3.2, GPMC CS0 Default Configuration at IC Reset](#).

10.1.5.14 NAND Device Basic Programming Model

NAND (8-bit and 16-bit) memory devices using a classical NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to chip enable dont care NAND devices since the chip-select allocated to the NAND device has to be de-asserted if accesses to other chip-selects are requested.

10.1.5.14.1 NAND Memory Device in Byte or Word16 Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or Word16).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

10.1.5.14.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC.[GPMC_CONFIG7_i](#) register (where $i = 0$ to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC.[GPMC_CONFIG1_i](#) register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in [Table 10-4](#). Failure to comply with these settings corrupts the NAND interface protocol.

Table 10-4. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] ⁽¹⁾	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26:25]	00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13:12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9]	0	Nonmultiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

⁽¹⁾ $i = 0$ to 7

The GPMC.[GPMC_CONFIG1_i](#) to GPMC.[GPMC_CONFIG4_i](#) register (where $i = 0$ to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

10.1.5.14.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The CPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC.[GPMC_NAND_COMMAND_i](#) and GPMC.[GPMC_NAND_ADDRESS_i](#) register locations ($i = 0$ to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC.[GPMC_NAND_COMMAND_i](#) register location and to the GPMC.[GPMC_NAND_ADDRESS_i](#) register location must be posted for faster operations ($i = 0$ to 7). The GPMC.[GPMC_CONFIG\[0\]](#) NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC.[GPMC_STATUS\[0\]](#) EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

GPMC.[GPMC_NAND_COMMAND_i](#) and GPMC.[GPMC_NAND_ADDRESS_i](#) ($i = 0$ to 7) are Word32 locations, which means any Word32 or Word16 access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use Word32 or Word16 access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to GPMC.[GPMC_NAND_COMMAND_i](#) and GPMC.[GPMC_NAND_ADDRESS_i](#) can be used, and any of the four byte locations of the registers are valid.

The same applies to a GPMC.[GPMC_NAND_COMMAND_i](#) and a GPMC.[GPMC_NAND_ADDRESS_i](#) ($i = 0$ to 7) Word32 write access to a 16-bit wide NAND device (split into two Word16 accesses). In the case of a Word16 write access, the MSByte of the Word16 value must be set according to the NAND device requirement (usually 0). Either Word16 location or any one of the four byte locations of the registers is valid.

10.1.5.14.1.3 Command Latch Cycle

Writing data at the GPMC.[GPMC_NAND_COMMAND_i](#) location ($i = 0$ to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFETIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 10-22 shows the NAND command latch cycle.

Figure 10-22. NAND Command Latch Cycle

NOTE: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte enable signals.

10.1.5.14.1.4 Address Latch Cycle

Writing data at the GPMC.GPMC_NAND_ADDRESS_i location ($i = 0$ to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFETIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 10-23 shows the NAND address latch cycle.

Figure 10-23. NAND Address Latch Cycle

NOTE: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

10.1.5.14.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC.[GPMC_NAND_DATA_i](#) location ($i = 0$ to 7) mapped in the chip-select-associated control register region. GPMC.[GPMC_NAND_DATA_i](#) is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC.[GPMC_NAND_DATA_i](#) location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFETIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and device IC timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 10-24 shows the NAND data read cycle.

Figure 10-24. NAND Data Read Cycle

gpmc-024

Writing data to the GPMC.[GPMC_NAND_DATA_i](#) location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFETIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 10-25 shows the NAND data write cycle.

Figure 10-25. NAND Data Write Cycle

gpmc-025

10.1.5.14.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFETIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses. For more information about optimal prefetch engine access, see [Section 10.1.5.14.4, Prefetch and Write-Posting Engine](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

10.1.5.14.1.7 Read and Write Access Size Adaptation

10.1.5.14.1.7.1 8-Bit Wide NAND Device

Host Word16 and Word32 read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0:D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

10.1.5.14.1.7.2 16-Bit Wide NAND Device

Host Word32 read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write Word16 accesses to the NAND memory device. Word16 access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a Word16 basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or Word16 read access gets the next Word16 NAND location. For a write access, the invalid byte part of the Word16 is driven to FF, and the next byte or Word16 write access programs the next Word16 NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

10.1.5.14.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the four WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 μ s) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

NOTE: If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC.[GPMC_CONFIG1_i\[21\]](#) WAITWRITEMONITORING and GPMC.[GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bits to 0, where $i = 0$ to 7), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit ($n = 0$ to 3) of the [GPMC_STATUS](#) register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC.[GPMC_IRQENABLE](#) register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the [GPMC_STATUS](#) register.

The READWAITMONITORING bit method must be used for memories other than NAND flash, if they require the use of a WAIT signal.

10.1.5.14.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC.[GPMC_STATUS](#) WAITxSTATUS bit ($x = 0$ to 3). The software must monitor the ready pin only when the signal is declared valid. See the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

10.1.5.14.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC.[GPMC_CONFIG](#) WAITxPINPOLARITY bits ($x = 0$ to 3) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1

to the WAITxEDGEDETECTIONSTATUS bit ($x = 0$ to 3) of the GPMC.[GPMC_IRQSTATUS](#) register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC.[GPMC_IRQENABLE](#) register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC.[GPMC_IRQSTATUS](#) register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC.[GPMC_IRQSTATUS](#) register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

10.1.5.14.3 ECC Calculator

The general-purpose memory controller includes an error code correction (ECC) calculator circuitry that enables on-the-fly ECC calculation during data read or data program (that is, write) operations.

The user can choose from two different algorithms with different error correction capabilities: Hamming code (for 1-bit error code correction), and BCH code (for 4- or 8-bit error correction) through the [GPMC_ECC_CONFIG\[16\]](#) ECCALGORITHM bit. Only one ECC context can be active at any given time through the [GPMC_ECC_CONFIG\[3:1\]](#) ECCCS bit. Even if two CSs use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts, because some of the ECC registers are common to all types of algorithms.

10.1.5.14.3.1 Hamming Code

All references to ECC in this section refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming code. The parity accumulation is done for a programmed number of bytes or Word16 read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

10.1.5.14.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC.[GPMC_ECCj_RESULT](#), $j = 1$ to 9) to store ECC computation results when the specified number of bytes or Word16s has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The GPMC.[GPMC_ECCj_RESULT](#) register value is valid only when the programmed number of bytes or Word16s has been accumulated, which means that the same number of bytes or Word16s has been read from or written to the NAND device in sequence.

The GPMC.[GPMC_ECC_CONTROL](#)[3:0] ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The GPMC.[GPMC_ECCj_RESULT](#) register value ($j = 1$ to 9) can be considered valid when ECCPOINTER equals $j + 1$. When GPMC.[GPMC_ECCj_RESULT](#) (where $j = 9$) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC.[GPMC_ECC_CONTROL](#)[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC.[GPMC_ECCj_RESULT](#) register, $j = 1$ to 9), the number of bytes or Word16s used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits ($j = 1$ to 9) in the GPMC.[GPMC_ECC_SIZE_CONFIG](#) register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC.[GPMC_ECCj_RESULT](#)).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or Word16s used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or Word16s used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 Word16, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-Kbyte data page 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC.[GPMC_ECCj_RESULT](#) registers ($j = 1$ to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8]RESULTSIZE bits are set to 0, and the ECC9RESULTSIZE bit is set to 1.

10.1.5.14.3.1.2 ECC Enabling

The GPMC.[GPMC_ECC_CONFIG](#)[3:0] ECCCS field selects the allocated chip-select. The GPMC.[GPMC_ECC_CONFIG](#)[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSIZE (where $j = 1$ to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 10-5 describes the ECC enable settings.

Table 10-5. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0 -7	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0 -7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0 -7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00 -0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00 - 0xFF	Defines ECCSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

10.1.5.14.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in [Figure 10-26](#) and [Figure 10-27](#). The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

$P1o = \text{bit7 XOR bit5 XOR bit3 XOR bit1}$ on each byte of the data stream

$P1e = \text{bit6 XOR bit4 XOR bit2 XOR bit0}$ on each byte of the data stream

$P2o = \text{bit7 XOR bit6 XOR bit5 XOR bit4}$ on each byte of the data stream

$P2e = \text{bit5 XOR bit4 XOR bit1 XOR bit0}$ on each byte of the data stream

$P4o = \text{bit7 XOR bit6 XOR bit5 XOR bit4}$ on each byte of the data stream

$P4e = \text{bit3 XOR bit2 XOR bit1 XOR bit0}$ on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 10-26. Hamming Code Accumulation Algorithm (1/2)

gpmc-026

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

$P8e = \text{row0 XOR row2 XOR row4 XOR row254}$

$P8o = \text{row1 XOR row3 XOR row5 XOR row255}$

$P16e = \text{row0 XOR row1 XOR row4 XOR row5 XOR row252 XOR row253}$

$P16o = \text{row2 XOR row3 XOR row6 XOR row7 XOR row254 XOR row255}$

Figure 10-27. Hamming Code Accumulation Algorithm (2/2)

gpmc-027

Unused parity bits in the result registers are set to 0.

[Figure 10-28](#) shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 10-28. ECC Computation for a 256-Byte Data Stream (Read or Write)

gpmc-028

[Figure 10-29](#) shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

Figure 10-29. ECC Computation for a 512-Byte Data Stream (Read or Write)

gpmc-029

For a 2-Kbytes page, four 512-byte ECC calculations plus one for the spare area are required. Results are stored in the [GPMC_ECCj_RESULT](#) registers ($j = 1$ to 9).

10.1.5.14.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

10.1.5.14.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

10.1.5.14.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the [GPMC_ECC_CONFIG\[7\]](#) ECC16B bit must be set to 0 when interfacing an 8-bit wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while they are computed on columns for a 16-bit based ECC. [Figure 10-30](#) and [Figure 10-31](#) show a 128 Word 16 ECC computation scheme and a 256 Word16 ECC computation scheme.

Figure 10-30. 128 Word16 ECC Computation

gpmc-030

Figure 10-31. 256 Word16 ECC Computation

gpmc-031

10.1.5.14.3.2 BCH Code

All references to ECC in this section refer to the 4- or 8-bit error correction BCH code.

10.1.5.14.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first, the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses.

Typical page write sequence:

- Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.

- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array.

Typical page read sequence:

- Sequential read of a page. ECC is calculated on-the-fly.
- ECC module buffers status determines the presence of errors.

- Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
 - Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to $8 * 512$ -byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.
- The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
- NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.
 - The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

10.1.5.14.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message $M(x)$. In our standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} - 1 = 4095$, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction. The ECC is a remainder polynomial $R(x)$ of degree 103 (or 51, depending on the selected mode). The complete codeword $C(x)$ is the concatenation of $M(x)$ and $R(x)$ as shown in [Table 10-6](#).

Table 10-6. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message $M(x)$			ECC $R(x)$		
Bit number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message $M(x)$ of degree $((512 + 3) * 8) - 1 = 4119$, for a total of $3+13 = 16$ spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in [GPMC_BCH_RESULT0_i](#), [GPMC_BCH_RESULT1_i](#), [GPMC_BCH_RESULT2_i](#), and [GPMC_BCH_RESULT3_i](#) (where $i = 0$ to 7).

10.1.5.14.3.2.2.1 Memory-Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LS bit) represents a segment of polynomial $b7 * x^{(7+i)} + b6 * x^{(6+i)} + \dots + b0 * x^i$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

NOTE: The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 10-7 and **Table 10-8** describe the mapping of the same 512-byte vector (typically a BCH message) in the NAND memory space. The byte "address" is only an offset modulo 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and M($2^{12}-1$) of the codeword mapping given previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAMs data word boundaries.

Table 10-7. Aligned Message Byte Mapping in 8-bit NAND

Byte Offset	8-Bit Word
0x000	(msb) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (lsb)

Table 10-8. Aligned Message Byte Mapping in 16-bit NAND

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(msb) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...
0x1FE	Byte 0 (0x0)	(lsb) Byte 1 (0x1)

Table 10-9 through **Table 10-14** show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. The message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded; they can still be used by the BCH module, but as part of the next message section (for example, on another sector ECC).

Table 10-9. Aligned Nibble Mapping of Message in 8-bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Less Significant Nibble
1	(msb) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...
S/2 - 2	Nibble 3	Nibble 2
S/2 - 1	Nibble 1	Nibble 0 (lsb)

Table 10-10. Misaligned Nibble Mapping of Message in 8-bit NAND

...
(S+3)/2 - 4	Nibble 2	Nibble 1	Nibble 4
(S+3)/2 - 2			Nibble 3
			Nibble 0 (lsb)

Many cases exist other than the ones previously given; for example, where the message does not start on a word boundary.

10.1.5.14.3.2.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 bytes) from the modules interface, and then store them to the NAND spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error has been detected. The creation of this codeword must be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

10.1.5.14.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see [Section 10.1.5.14.3.2.3](#).

For each mode:

- A sequence describes the mode in pseudo-language, with the size and the buffer used for ECC processing (if ON) for each section. The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) one unused nibble to remain byte-aligned.

10.1.5.14.3.2.2.4 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses: we must program size0 = 5, size1 = 3).

NOTE: In the following figures size and size0 are the same parameter.

Figure 10-32. Manual Mode Sequence and Mapping

gpmc-032

Section processing sequence:

- One time with buffer
 - size0 nibbles of data, processing ON
 - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

10.1.5.14.3.2.2.5 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

10.1.5.14.3.2.2.6 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - 1 nibble pad spare, processing OFF
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

10.1.5.14.3.2.2.7 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

10.1.5.14.3.2.2.8 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

10.1.5.14.3.2.2.9 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S - size1)

10.1.5.14.3.2.2.10 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

10.1.5.14.3.2.2.11 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

10.1.5.14.3.2.2.12 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON

- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

10.1.5.14.3.2.2.13 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

10.1.5.14.3.2.2.14 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

10.1.5.14.3.2.2.15 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

10.1.5.14.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 10.1.5.14.3.2.2.1](#).

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

A table on the left summarizes the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where :

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares; that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, programmed sizes, and sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
 - all sectors: $(512) + P + E$
- Spares pooled and protected by sector 0 (below: see M5-M6):
 - sector 0 codeword: $(512) + P + E$
 - other sectors: $(512) + E$
- Unprotected spares (below: see M4-M7-M8-M11-M12):
 - all codewords $(512) + E$

10.1.5.14.3.2.3.1 Per-Sector Spare Mappings

In the schemes in [Figure 10-33](#), each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of :

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the sector ECC

Figure 10-33. NAND Page Mapping and ECC: Per-Sector Schemes

10.1.5.14.3.2.3.2 Pooled Spare Mapping

In the schemes in [Figure 10-34](#), the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0.

10.1.5.14.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MCU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine uses an embedded 64 bytes (32 Word16) FIFO to prefetch data

from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MCU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MCU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC.[GPMC_PREFETCH_CONFIG1\[23\]](#) PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC.[GPMC_PREFETCH_CONFIG1\[19:16\]](#) PFPWWIGHTEDPRIO field.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access). The engine does not include an address generator, and the request is limited to chip-select target identification. The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

NOTE: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

10.1.5.14.4.1 General Basic Programming Model

The engine can be configured only if the GPMC.[GPMC_PREFETCH_CONTROL\[0\]](#) STARTENGINE bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC.[GPMC_PREFETCH_CONFIG1\[26:24\]](#) ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine uses byte or Word16 access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes.

When the GPMC.[GPMC_PREFETCH_CONFIG1\[7\]](#) ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the GPMC.[GPMC_NAND_COMMAND_i](#), GPMC.[GPMC_NAND_ADDRESS_i](#), and GPMC.[GPMC_NAND_DATA_i](#) registers (where i = 0 to 7).

The FIFO entry on the L3 interconnect port can be accessed with byte, Word16, or Word32 access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC.GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC.GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of Word32 or Word16 read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location). There is no underflow or overflow error reporting in the GPMC.

10.1.5.14.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC.GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MCU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC.GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (configured, reset, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC.GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the GPMC.GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see [Section 10.1.5.14.2.2](#). The GPMC.GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to ensure that the FIFO is always filled with as much data as acceptable, until the programmed GPMC.GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT field is completed.

Table 10-15. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 7	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select

Table 10-15. Prefetch Mode Configuration (continued)

Bit Field	Register	Value	Comments
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17:16]	0 to 3	(If SynchroMode = 1) Selects wait pin edge detector
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 10.1.5.14.4.6 .
CYCLOOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

10.1.5.14.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC.GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER field or through the GPMC.GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC.GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC.GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC.GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC.GPMC_IRQENABLE[1] TERMINALCOUNTENABLE bit is set. At prefetch completion, thee TERMINALCOUNT interrupt event is also logged, and the GPMC.GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is triggered only when COUNTVALUE reaches 0 (that is, when the prefetch engine automatically goes from an active to inactive state).

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC.GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOThreshold, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

10.1.5.14.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC.GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MCU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC.GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MCU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC.GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC.GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MCU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 10-16. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTION	GPMC_PREFETCH_CONFIG1[26:24]	0 to 7	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOThreshold	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 10.1.5.14.4.6 .
CYCLOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		

Table 10-16. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

10.1.5.14.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC.GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC.GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC.GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC.GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC.GPMC_IRQENABLE[1] TERMINALCOUNTENABLE bit is set. When the interrupt is fired, the GPMC.GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0 (that is, when the posting engine automatically goes from active to inactive).

In DMA filling mode, the DMAMode bit field in the GPMC.GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

10.1.5.14.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no

accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC.GPMC_NAND_DATA_i location, i = 0 to 7) are never optimized.

The GPMC.GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC.GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFETIME, and WEOFETIME timing parameters.

Figure 10-36 highlights that, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION field.

Figure 10-36. NAND Read Cycle Optimization Timing Description

gpmc-036

10.1.5.14.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC.GPMC_PREFETCH_CONFIG1[23]

PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC.GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

10.1.6 GPMC Use Cases and Tips

10.1.6.1 How to Set GPMC Timing Parameters for Typical Accesses

10.1.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

10.1.6.1.2 Typical GPMC Setup

Table 10-17 lists some of the I/Os of the GPMC module.

Table 10-17. GPMC Signals

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	I/O	External clock provided to the external device for synchronous operations
gpmc_a[11: 1]	O	Address
gpmc_d[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_ncs	O	Chip-select
gpmc_nadv_ale	O	Address valid enable
gpmc_noe_nre	O	Output enable (read access only)
gpmc_nwe	O	Write enable (write access only)
gpmc_wait[3:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

[Figure 10-37](#) shows the typical connection between the GPMC module and an attached NOR flash memory.

Figure 10-37. GPMC Connection to an External NOR Flash Memory

gpmc_037

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

10.1.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz ($f = 104$ MHz; $T = 9,615$ ns).

[Table 10-18](#) shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

[Table 10-19](#) shows how to calculate timings for the GPMC using the memory parameters.

[Figure 10-38](#) shows the synchronous burst read access.

Table 10-18. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80

Table 10-18. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One burst of data is processed in one clock cycle ($T = 9,615 \text{ ns}$). The read access time between two bursts of data is $tBACC = 5,2 \text{ ns}$. Therefore, data setup time is a clock period - $tBACC = 4,415 \text{ ns}$ of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 10-19. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94,03: (9,615 + 80 + 4,415)	10 : roundmax (94,03 / 9,615)	ACCESSTIME = 0x0A
PageBurstAccessTime	roundmax (tBACC)	roundmax (5,2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	AccessTime + max (tCEZ, tOEZ)	101, 03: (94, 03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC ⁽¹⁾	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC ⁽²⁾	12	2	ADVRDOFFTIME = 0x02
OeOnTime ⁽³⁾	(ClkActivationTime + tACH) < OeOnTime < (ClkActivationTime + tIACC)	-	3 for instance.	OEONTIME = 0x3
OeOffTime	RdCycleTime	-	11	OEOFETIME = 0x0B

⁽¹⁾ The external clock provided to the NOR flash is not yet available.

⁽²⁾ AdvRdOffTime - AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.

⁽³⁾ OeOnTime must guarantee that addresses are available. It must not exceed the availability of the first burst of data.

Figure 10-38. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)

10.1.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz ($f = 104$ MHz; $T = 9,615$ ns).

[Table 10-20](#) shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

[Table 10-21](#) shows how to calculate timings for the GPMC using the memory parameters.

[Figure 10-39](#) shows the asynchronous read access.

Table 10-20. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$\text{RdCycleTime} = \text{RdAccessTime} + \text{AccessCompletion} = \text{RdAccessTime} + 1 \text{ clock cycle} + \text{tOEZ}$$

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in [Table 10-20](#): the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

The GPMC side requires some hold to allow the data to be captured correctly and the access to be finished.

- To read the data correctly, the GPMC must capture it with enough data setup time; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is 1 clock cycle (AccessTime + 1).

- To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

Table 10-21. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
AccessTime	round max (tCE)	80	9	ACCESSTIME = 0x09
PageBurstAccess Time	n/a (single access)			
RdCycleTime	AccessTime + 1cycle + tOEZ	96, 615	11	RDCYCLETIME = 0x0B
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	AccessTime + 1 cycle	89, 615	10	CSRDOFFTIME = 0x0A
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0X1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3 for instance	OEONTIME = 0x3
OeOffTime	AccessTime + 1cycle	89, 615	10	OEOFDTIME = 0x0A

Figure 10-39. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)

10.1.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 10-23 shows how to calculate timings for the GPMC using the memory parameters.

Table 10-22 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 10-40 shows the synchronous burst write access.

Table 10-22. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccessCompletion: 1 cycle is required for data hold time (nCS deassertion).

Table 10-23. GPMC Timing parameters for Asynchronous Single Write

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime		n/a (asynchronous mode)		
AccessTime		Applicable only to WAITMONITORING (the value is the same as for read access)		
PageBurstAccessTime		n/a (single access)		
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVVROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x05

10.1.6.2 How to Choose a Suitable Memory to Use With the GPMC

This section explains how to select a suitable memory device to interface with the GPMC.

10.1.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, OneNAND™)
- 8- and 16-bit NAND flash device

NOTE: Nonmultiplexed NOR flash devices are supported by the GPMC, but their use is highly limited. Because only ten address pins are available on the GPMC interface, the maximum device size supported is 2KB.

10.1.6.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the supported GPMC memories.

Table 10-24. Supported Memory Interfaces

Function	16-Bit Address/Data Muxed pSRAM or NOR Flash ⁽¹⁾	OneNAND	16-bit NAND	8-bit NAND
gpmc_a11	A27			
gpmc_a10	A26			
gpmc_a9	A25			
gpmc_a8	A24			
gpmc_a7	A23			
gpmc_a6	A22			
gpmc_a5	A21			
gpmc_a4	A20			
gpmc_a3	A19			
gpmc_a2	A18			
gpmc_a1	A17			
gpmc_d15	D15 or A16		IO15	
gpmc_d14	D14 or A15		IO14	
gpmc_d13	D13 or A14		IO13	
gpmc_d12	D12 or A13		IO12	
gpmc_d11	D11 or A12		IO11	
gpmc_d10	D10 or A11		IO10	
gpmc_d9	D9 or A10		IO9	
gpmc_d8	D8 or A9		IO8	
gpmc_d7	D7 or A8			IO7
gpmc_d6	D6 or A7			IO6
gpmc_d5	D5 or A6			IO5
gpmc_d4	D4 or A5			IO4
gpmc_d3	D3 or A4			IO3
gpmc_d2	D2 or A3			IO2
gpmc_d1	D1 or A2			IO1
gpmc_d0	D0 or A1			IO0

⁽¹⁾ Addresses seen from the device side. When interfacing to the external IC, A1 is connected to the memory A0, A2 to the memory A1, and so on.

Table 10-24. Supported Memory Interfaces (continued)

Function	16-Bit Address/Data Muxed pSRAM or NOR Flash ⁽¹⁾	OneNAND	16-bit NAND	8-bit NAND
gpmc_clk	CLK			
gpmc_ncs0	nCS0 (chip select)		nCE0 (chip enable)	
gpmc_ncs1	nCS1		nCE1

gpmc_wait2	WAIT2		R/nB2	
gpmc_wait3	WAIT3		R/nB3	

10.1.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device (that is, read and write accesses are done by pages). NAND achieves density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density, NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. Because of its nonvolatility, NAND is a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 10-25 summarizes the level of the NAND interface signals applied to external devices or memories.

Table 10-25. NAND Interface Bus Operations Summary

Bus operation	CLE	ALE	nCE	nWE ⁽¹⁾	nRE ⁽¹⁾	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H ⁽²⁾	H ⁽²⁾	H ⁽²⁾	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L ⁽³⁾

⁽¹⁾ RE stands for rising edge, FE stands for falling edge.

⁽²⁾ Can be either nCE high, or WE and nRE high

⁽³⁾ nWP must be biased to CMOS high or CMOS low for standby.

10.1.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable (that is, it is designed to be a random access device). NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it has slow write and erase functions compared to NAND architecture.

[Table 10-26](#) summarizes the level of the NOR interface signals applied to external devices or memories.

Table 10-26. NOR Interface Bus Operations Summary

Bus operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

10.1.6.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

OneNAND is a high density and low-power memory device. OneNAND is based on a single- or multilevel-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR flash; it also has synchronous write capability. It reads faster than conventional NAND and writes faster than conventional NOR flash. Therefore, it is appropriate for both mass storage and code storage.

pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash; it also has synchronous write capability.

10.1.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

10.1.6.2.2 GPMC Features and Settings

This section lists the GPMC features and settings:

- Supported device type: up to eight NAND or NOR protocol external memories or devices
- Operating voltage: 1.8 V
- Maximum operating frequency provided externally: up to 100 MHz (single device) with an L3-clock of 100 MHz. Up to 83 MHz (L3-clock divided by two) with an L3-clock of 166 MHz.
- Maximum GPMC addressing capability: 1 GB divided into eight chip-selects
- Maximum supported memory size: 256 MB (must be a power-of-2)
- Minimum supported memory size: 16 MB (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping and bus turnaround

10.1.7 GPMC Register Manual

10.1.7.1 GPMC Instance Summary

Table 10-27 describes the GPMC instance.

10.1.7.3 GPMC Register Description

This section provides a description of GPMC registers.

NOTE: All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to [GPMC_NAND_DATA_i](#) register, are little endian. If the [GPMC_NAND_DATA_i](#) register location is accessed, the endianness is access-dependent.

10.2 SDRAM Controller (SDRC) Subsystem

This section describes the SDRAM controller (SDRC) subsystem.

10.2.1 SDRC Subsystem Overview

The SDRC subsystem module provides connectivity between the device POP-ed SDRAM memory components. The module includes support for low-power double-data-rate SDRAM (LPDDR1).

The SDRC subsystem provides a high-performance interface to a variety of fast memory devices. It comprises two submodules:

- The SDRAM memory scheduler (SMS), consisting of scheduler and virtual rotated frame-buffer (VRFB) modules
- The SDRC

CAUTION

DDR SDRAM and SDR SDRAM memory types cannot be connected simultaneously to the SDRC memory interface.

Figure 10-41 shows the SDRC subsystem environment.

Figure 10-41. SDRC Subsystem Environment

sdrc-001

10.2.1.1 Features

The main features of the SDRC subsystem module are:

- VRFB module
 - Minimizes SDRAM page-miss penalty when accessing graphics buffer in nonnatural raster-scan order
 - Supports rotations of 0, 90, 180, and 270 degrees
 - Transparent to software applications
 - 12 concurrent rotation contexts
- Memory-access scheduler
 - Optimizes latency and bandwidth usage between initiators
 - Per-system initiator group quality-of-service (QoS) control
 - 8 * 8 * 64 request queue FIFO for optimal scheduling
 - Programmable arbitration scheme
 - Focus on real-time memory processes (DSS display, camera interface)

- Focus on MPU/DSP memory latency
- Fair arbitration between other system initiators (DMAs, video subsystem, GFX accelerator)
- Exclusive read-write transaction support
- SDRAM Controller
 - Support for two independent CSs, with their corresponding register sets, and independent page tracking
 - Supports the following memory types:
 - Mobile Single Data Rate SDRAM (M-SDR)
 - Low-Power Double Data Rate SDRAM (LPDDR)
 - Memory device capacity:
 - 16 Mbits, 32 Mbits, 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit, 2 Gbits, and 4 Gbits device support
 - Memory device organization
 - 2-bank support for 16 Mbits and 32 Mbits
 - 4-bank support for 64 Mbits to 4 Gbits
 - Flexible row/column address multiplexing schemes
 - Bank linear addressing
 - 16- or 32-bit data path to external SDRAM memory
 - 1GB maximum addressing capability
 - Device driver strength feature for mobile DDR supported
 - New flexible address-muxing scheme lets users choose different bank mapping allocations by configuring the bank and column address decoding ordering.
 - Fully pipelined operation for optimal memory bandwidth usage
 - Burst support
 - Memory burst support
 - System burst for SDR SDRAM: system burst translated into memory burst of 2
 - System burst for mobile DDR SDRAM: system burst translated into memory burst size of 4
 - Read interrupt by read, write interrupt by write
 - CAS latency support 1, 2, 3, 4, 5
 - Fully programmable ac timing parameters (on a per-parameter basis). Parameters are set according to the memory interface clock frequency with respect to the attached memory device timing specifications.
 - Fine tuning of the controlled delay elements when operating with DDR memory
 - Dynamic endianness support
 - 9 * 64 bit lookahead FIFO in the SDRAM controller with a maximum of four transaction entries
 - Low-power management support
 - Dynamic power-saving features (internal clock gating)
 - Static power-saving features
 - Support for all standard low-power memory features
 - Support for enhanced low-power features (mobile devices)
 - Very low-power controlled-delay technology for optimal performance with DDR memory
 - Can operate with mobile DDR memory at very low clock rates
 - Autorefresh and self-refresh management

NOTE: The device does not support regular devices, SDR or DDR, because of electrical incompatibility.

10.2.2 SDRC Subsystem Environment

10.2.2.1 SDRC Subsystem Description

Figure 10-42 shows the SDRC subsystem interfacing with one 16- and one 32-bit SDR external memories. Figure 10-43 shows the SDRC subsystem interfacing with one 16- and one 32-bit DDR memories.

Figure 10-42. SDRC Subsystem Connections to SDR SDRAM

sdrc-002

Figure 10-43. SDRC Subsystem Connections to DDR SDRAM**CAUTION**

Both memory types (SRD/DDR SDRAM) cannot be connected simultaneously to the SDRC memory interface.

Table 10-95 lists SDRC subsystem I/O pins.

Table 10-95. SDRC Subsystem I/O Description

Pin	Type	Description
sdrc_d[31:0]	I/O	32-bit wide data bus
sdrc_ba[1:0]	O	Bank address 1-0
sdrc_a[14:0]	O	Address bus

Table 10-95. SDRC Subsystem I/O Description (continued)

Pin	Type	Description
sdrc_ncs[1:0]	O	Chip-select 1-0 (active low)
sdrc_clk	O	Clock ⁽¹⁾
sdrc_nclk	O	Clock invert (DDR only)
sdrc_cke0	O	Clock enable (CS0)
sdrc_cke1	O	Clock enable (CS1)
sdrc_nras	O	Row address strobe (active low)
sdrc_ncas	O	Column address strobe (active low)
sdrc_nwe	O	Write enable (active low)
sdrc_dm[3:0]	O	Data mask/OE for SDR read operation
sdrc_dqs[3:0]	I/O	Data output strobe (DDR only)

⁽¹⁾ This output signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

10.2.2.2 External Interface Configuration

10.2.2.2.1 CS0, CS1 Memory Spaces

The SDRC can be connected independently to two external SDRAM memories.

Mobile SDR SDRAM memory is supported in sizes of 16 Mbits, 32 Mbits, 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit, 2 Gbits, and 4 Gbits. See [Section 10.2.4.4.1](#) for more information on CS memory spaces.

NOTE: The device does not support regular devices, SDR or DDR (see [Section 10.2.5.3.1](#), *Chip-Select Configuration*).

10.2.2.2.2 AC Timing Control

The SDRC permits the configuration of many of the ac timing parameters controlling the SDRAM transaction timing.

It is required to adapt the transaction timing parameters to any memory device attached to the SDRC.

A totally independent, complete set of parameters exists for each CS. The ac parameters and their quantification are summarized in [Section 10.2.5.3.1](#), *Chip-Select Configuration*.

10.2.2.2.3 Address Multiplexing

A flexible address scheme has been added to support any new type of address scheme and SDRAM density. This new address-muxing scheme lets users choose a different bank mapping allocation by configuring the order of the bank and row address decoding (column address always remains the same). The SDRC.[SDRC_MCFG_p\[7:6\]](#) BANKALLOCATION field defines the order of the bank and row decoding of the incoming system address. The BANKALLOCATION field can be set on a CS basis. For more details about the flexible address scheme, see [Section 10.2.4.4.3](#), *Address Multiplexing*.

The programming model is compatible with the legacy fixed address scheme and with the new flexible address scheme. This section describes the fixed address multiplexing configurations for both SDRAM components.

The legacy fixed address scheme is selected when the SDRC.[SDRC_MCFG_p\[19\]](#) ADDRMUXLEGACY bit is set to 0 (where p = 0 or 1 for SDRC CS0 or CS1). The fixed address multiplexing configurations are described in this section, for both SDRAM components. An address multiplexing scheme is chosen by programming the SDRC.[SDRC_MCFG_p\[24:20\]](#) ADDRMUX field of the SDRC_MEMCFG registers on a per chip select basis (p = 0 or 1 for CS0 or CS1). [Table 10-96](#) and [Table 10-97](#) show all predefined address multiplexing schemes for SDRAM memory components.

Table 10-96. SDRC Address Multiplexing Scheme Selection vs SDRAM Configurations (x16 Memory Interface)

x16 Memory Interface

								1	64M x 32
BA1, BA0	2	A0-A9	10	A0-A14	15	MUX29	4096	1	128M x 32
BA1, BA0	2	A0-A9; A11	11	A0-A12	13	MUX15	2048	4	64M x 8
								2	64M x 16
								1	64M x 32

Table 10-96 is valid per CS (in the table, the total size in Mbits corresponds to a single CS). Both chips must use the same address scheme, but can use different address multiplexing configurations.

[Figure 10-44](#) through [Figure 10-46](#) show all the SDRAM MUX schemes, including the mapping of the 32-bit system address of the column and row addresses of the memory device.

NOTE: The bank-select bit (BA1) does not exist for 2-bank devices.

10.2.3 SDRC Subsystem Integration

Figure 10-47 shows how the SMS and SDRC modules are integrated into the device and how they interact with the PRCM module.

Figure 10-47. SDRC Integration to the Device

sdrc-007

10.2.3.1 Clocking, Reset, and Power Management Scheme

10.2.3.1.1 Clocking

10.2.3.1.1.1 SMS

The SMS is a single clock domain module. The same clock is used for the interconnect system interface, the SDRC interface, and all internal operations.

SMS_CLK comes internally from the PRCM module and runs at the L3 interconnect frequency. It is also used as a functional clock for the SMS module.

The source of the SMS_CLK is the PRCM CORE_L3_ICLK output: CORE_L3_ICLK belongs to the L3 interconnect clock domain.

10.2.3.1.1.2 SDRC

The SDRC is a single-clock domain module. The same clock is used for the interconnect and the memory interface. The SDRC_CLK clock comes from the PRCM and runs at the L3 interconnect frequency. SDRC_CLK is also used as a functional clock for the SDRC.

The SDRC_CLK clock source is the PRCM CORE_L3_ICLK output: CORE_L3_ICLK belongs to the L3 interconnect clock domain.

An SDRC_CLKX2 clock is provided by the PRCM at a double frequency of the SDRC_CLK clock. This clock can be used in the LPDDR write path, depending on the configuration.

As a power-saving feature, when the SDRC no longer requires the clock domain, the software can disable it at the PRCM level by setting the EN_SDRC bit in the PRCM.CM_ICKLEN1_CORE[1] register.

NOTE: The domain clock is shut down only if all other modules that receive the clock are capable and ready to accept this idle request and have IdleAck asserted.

For details, see [Chapter 3, Power, Reset, and Clock Management](#).

10.2.3.1.2 Hardware Reset

Global reset of the SDRC is done by activating the CORE_RST signal in the CORE_RST domain (see [Chapter 3, Power, Reset, and Clock Management](#)).

There is one global reset signal, SDRC_GLOBALRESET, which is qualified by the signal SDRC_POWERON. This qualification differentiates whether the signal is a cold reset or a warm reset.

- On a cold reset (that is, the power-on reset, when SDRC_POWERON = 0 and SDRC_GLOBALRESET is applied), all registers and state-machines within the SDRC are asynchronously reset.
- On a warm reset (that is, any other system reset condition under control of the chip top-level power manager, SDRC_POWERON = 1 when SDRC_GLOBALRESET is applied), the SDRC registers and the FSM are not reset, but the external SDRAM memory can be optionally placed in self-refresh mode, depending on the configuration of the SDRC.[SDRC_POWER_REG](#)[7] SRFRONRESET bit.

10.2.3.1.3 Software Reset

The SMS and SDRC modules can be reset under software control through the SMS.[SMS_SYSCONFIG](#)[1] SOFTRESET and SDRC.[SDRC_SYSCONFIG](#)[1] SOFTRESET bits, respectively.

A software reset has the same action as a hardware cold reset; that is, the FSM and all registers are reset immediately and unconditionally.

10.2.3.1.4 Power Management

The SDRC power is supplied by the CORE power domain. For details, see [Chapter 3, Power, Reset, and Clock Management](#).

The dynamic voltage and frequency scaling (DVFS) technic is described in the following section while other power-saving features and different idle modes are described in [Section 10.2.4.4, SDRC](#).

10.2.3.1.4.1 Dynamic Voltage and Frequency Scaling

If the input clock SDRC_CLK from the PRCM module is changed during operations, the DLL may enter an undefined state and memory accesses may be corrupted. For this reason, it is necessary to manually assert the SDRC_IDLEREQ signal before any clock frequency change. This manual access is done through a register in the chip clock controller. The SDRC then finishes processing all open transactions. If this option is activated in the SDRC_POWER_REG[6] SRFRONIDLEREQ bit, it puts the memory into self-refresh. When done, it unlocks the DLL and puts it into a power-down state, through the SDRC.[SDRC_DLL_CTRL](#)[6:5] DLLMODEONIDLEREQ field. The SDRC then asserts the

SDRC_SIDLEACK signal and the input clock frequency can be changed or stopped, depending on the scenario. After the input clock is stable again, SDRC_IDLEREQ is de-asserted. The DLL then relocks and the SDRC can be accessed normally. Putting the DLL in idle mode during the clock frequency change is required because it cannot automatically relock. It might get into a non-functional state and a new manual DLL configuration phase would then be required, with the risk of corrupting accesses in the mean time.

10.2.4 SDRC Subsystem Functional Description

The SMS optimizes the SDRAM memory usage to provide:

- The QoS level required by each of the initiators in the system
- A VRFB module (also called the 2D rotation engine) that minimizes the SDRAM page-miss penalty when accessing rotated (that is, nonsequentially addressed) lines in a graphic frame buffer

10.2.4.1 SDRAM Memory Scheduler

The SMS module is split into the following subsystems:

- L3 interconnect slave port
- VRFB: Rotation engine (RE)
- Configuration register file
- Request buffers
- Arbitration logic
- SDRC interface: master port
- Debug port
- Response buffer

Figure 10-48 shows the top-level diagram of the SMS.

Figure 10-48. SMS Top-Level Diagram

10.2.4.1.1 Memory Access Scheduling

NOTE: For a description of the SMS mode of operation and arbitration policy, see [Section 10.2.6, SDRC Use Cases and Tips](#).

The SMS includes a set of FIFOs to queue the requests received from the system interconnect or processed by the RE. The FIFO entry contains a complete interconnect request, plus internal qualifiers added by the RE which are required to correctly process the requests modified (or generated) by the RE.

The SMS also includes a response FIFO, which is shared by all response threads. This FIFO provides full support for the response flow-control interconnect extension (handshake protocol).

When a memory transaction request arrives in the memory-access scheduler after being processed by the VRFB module, the request is sent to one of eight FIFO queues.

The allocation to a particular queue is fixed and depends on the source of the request. To prioritize concurrent transactions and optimize memory usage, each FIFO queue (and hence the memory-access request source) is categorized into one of these three arbitration classes:

- Class 0 (highest priority): For bandwidth-sensitive devices with severe real-time constraints. The system fails when the bandwidth requirement is not met. DSS or video display cores, camera capture cores belong to this category.
- Class 1: For latency-sensitive devices where system performance degrades severely when the average memory-access latency increases. These initiators also generally have some significant bandwidth requirements. All CPU cores are class 1 initiators.
- Class 2: For all other devices, possibly with high-bandwidth requirements but without being too latency-sensitive. Associated initiators may also have significant requirements in terms of bandwidth, but if the bandwidth budget requirement cannot be serviced, the system performance degrades, but remains functional (the system does not fail). General-purpose system DMA, multimedia accelerators (graphics, imaging, video) belong to this category.

The arbitration between Class 1 and Class 2 is programmable.

[Table 10-98](#) shows the mapping of FIFO queues and memory-access request sources to arbitration classes.

Table 10-98. Arbitration Class Allocation

Class	FIFO Queue	Source Device
0	6	D2D
	7	Display and Camera subsystems
1	0	MPU subsystem (instruction and data access)
	1	IVA2 subsystem (instruction, data access, and MMU)
2	2	IVA2 subsystem DMA (read and write), sDMA WR
	3	SGX
	4	USB (HS + FS), DAP
	5	sDMA (read)

A 2-level arbitration scheme determines the FIFO queue from which the next memory transaction is granted.

NOTE: In the register description, a group represents a FIFO queue of requests from the initiator.

10.2.4.1.2 Arbitration Policy

A 2-level arbitration scheme is implemented to grant access to the SDRC. The arbitration uses fully combinatorial logic, and the granted request is clocked before being issued on the interface master port of the SDRC.

- Intra-class arbitration: A first level of arbitration is done in parallel within each class between the different thread groups (request FIFOs).
- Interclass arbitration: A second level of arbitration is done among the three winners of the in-class arbitration.

10.2.4.1.2.1 Arbitration Policy Within a Burst and at a Burst Boundary

Arbitration is performed on the transaction boundary. The transaction can be either a single transaction or a burst transaction.

- Within a burst, if the thread cannot provide the subsequent request of the burst, a mechanism provides a wait for one idle cycle before moving the arbitration grant to the next thread. If only one idle cycle appears on one thread, an arbitration grant must not move (the next request served must be from the same thread). One idle cycle is then inserted in the SDRC request path.
- If the thread still cannot provide the request in the next cycle, the slot can be awarded to another initiator to avoid locking the SDRAM resource, if a thread cannot supply a subsequent request within the burst. In this case, there must not be a second idle cycle insertion in the SDRC request path. A burst with fewer than two idle cycles cannot be interrupted by a higher priority request.
- On burst boundary, the arbitration does not wait one idle cycle before moving the arbitration grant. As soon as the thread cannot request one transaction at a burst boundary, the arbitration grant can move to the next thread.

This is also valid within the ExtendedGrant and NOFsServices windows; as soon as the thread cannot request a transaction, the arbitration grant can move to the next thread. For more information, see the following descriptions of the ExtendedGrant and NOFsServices features.

10.2.4.1.2.2 Burst-Complete Feature (BURST-COMPLETE Field in *SMS_CLASS_ARBITER0*, *SMS_CLASS_ARBITER1*, and *SMS_CLASS_ARBITER2*)

A burst request can be submitted to the arbitration either as soon as the first request of the burst is received by the SMS or when at least one complete burst is buffered into the FIFO. The behavior is programmable on a per-group basis using the BURST-COMPLETE field of the *SMS_CLASS_ARBITER0*, *SMS_CLASS_ARBITER1*, and *SMS_CLASS_ARBITER2* registers. A per-FIFO counter tracks the number of complete bursts in a FIFO.

10.2.4.1.2.3 ExtendedGrant Feature (EXTENDEDGRANT Field in *SMS_CLASS_ARBITER0*, *SMS_CLASS_ARBITER1*, and *SMS_CLASS_ARBITER2*)

EXTENDEDGRANT is a programmable control field that allows a group to be granted for N consecutive transactions (single or burst), assuming the group is still requesting service (FIFO is not empty). EXTENDEDGRANT is applicable on a single/burst boundary. This multiple-service grant is intended to take advantage of the high probability of two consecutive transactions within a group accessing consecutive memory addresses (that is, in the same SDRAM page). This mechanism does not apply to consecutive transactions that have been split by the RE. The maximum number of consecutive grants is given in the EXTENDEDGRANT field of the *SMS_CLASS_ARBITER0*, *SMS_CLASS_ARBITER1*, and *SMS_CLASS_ARBITER2* registers. The allowed range is 1 to 3.

The ExtendedGrant logic is in the internal class arbitration but must be propagated to the interclass arbitration. The flag qualifying a second-service request is provided to the interclass arbiter so the extended grant scheme can be applied at the second level of arbitration.

- Class 0 requests can still override the ExtendedGrant scheme of class 1/class 2. Within an ExtendedGrant window, hand-over to another class/thread (granting another thread) can occur as soon as one idle cycle appears in the thread at burst or single boundary.
- The PWM counter of the interclass arbitration obeys the ExtendedGrant completion before handing priority to the other class.
- When a split transaction from the RE is interleaved within an ExtendedGrant window, completion of the ExtendedGrant window starts with the last ExtendedGrant counter value (not the initial value), because there are two independent counters for ExtendedGrant and NOFsServices. The ExtendedGrant counter is reloaded to its programmed value when it reaches 0.

10.2.4.1.2.4 NOFSERVICES Feature (SMS.SMS_CLASS_ROTATIONm[4:0] NOFSERVICES Field)

NOFSERVICES is a programmable control field that allows consecutive transactions (single or burst) coming from the VRFB (with an RE_split qualifier) to be granted consecutively, assuming the group is still requesting service (FIFO is not empty). NOFSERVICES is applicable to the RE single/burst boundary. The maximum number of consecutive grants is given by the NOFSERVICES field of the SMS.SMS_CLASS_ROTATIONm registers. The allowable range is 1 to 31.

The NOFSERVICES logic is in the internal class arbitration, but must be propagated to the interclass arbitration. The flag qualifying a second-service request is provided to the interclass arbiter so the extended grant scheme can be applied at the second level of arbitration.

- Class 0 requests can still override the NOFSERVICES scheme of class 1/class 2. Within a NOFSERVICES window, hand-over to another class/thread (granting another thread) can occur as soon as one idle cycle appears in the thread at burst or single boundary. A burst with fewer than two idle cycles cannot be interrupted by a class 0 request.
- The PWM counter of the interclass arbitration obeys the NOFSERVICES completion before handing priority to the other class.
- When a split transaction from the RE is interleaved within an ExtendedGrant window, completion of the NOFSERVICES window starts with the last NOFSERVICES counter value (not the initial value), because there are two independent counters for ExtendedGrant and NOFSERVICES.

If a transaction split by the VRFB follows a nonsplit transaction currently being executed on the SDRC side, an arbitration slot occurs on the nonsplit transaction boundary, regardless of the status of the ExtendedGrant counter. This is because the chances of a nonsplit transaction and a split transaction accessing the same SDRAM page are low. Similar behavior would be observed for a split transaction followed by a nonsplit transaction. The NOFSERVICES counter is reloaded with its programmed value when it reaches 0.

10.2.4.1.3 Internal Class Arbitration

Class 0, class 1, and class 2 internal arbitrations are performed according to the following rules:

- Within a class, a standard least-recently-used (LRU) policy is applied. The LRU thread, if not empty, is granted when an arbitration decision occurs. LRU is applied taking into account the ExtendedGrant/NOFSERVICES counter status. Grant is given to another nonempty LRU thread only if the current thread is serviced for ExtendedGrant/NOFSERVICES times.
- On top of the LRU policy, a high-priority group can be defined through the SMS.SMS_CLASS_ARBITER0[7:6] HIGHPRIOVECTOR field. The high-priority group is unique and programmable. If a high-priority thread in a class, which was previously empty, starts requesting service, the current thread that has been given grant is completely serviced as per ExtendedGrant/NOFSERVICES strategy and then the grant is given to the high-priority thread.

10.2.4.1.3.1 Interclass Arbitration

The interclass arbitration is managed using a time-varying policy driven by the following rules:

- The interclass arbitration is a PWM-like (Pulse Width Modulation) logic that defines two request-based windows:
 - Class 1 has higher priority than class 2 during M requests of class 1, where M is defined by the CLASS1PRIO parameter.
 - Class 2 has higher priority than class 1 during the next N requests of class 2, where N is defined by the CLASS2PRIO parameter. For more information on priority between classes, see [Section 10.2.6.2.2.3](#).
- The PWM counter is decremented each time the class is processing a single 64-bit request in its high-priority window.
- A class 0 request always has the highest priority. The PWM counter is frozen while class 0 requests are being serviced.
- A class 1 transaction can be serviced during the class 2 high-priority window if class 2 is not requesting service (conversely, a class 2 transaction can be serviced during the class 1 high-priority window if class 1 is not requesting service). The PWM counter is frozen when the grant is given to the

thread that is not in its high-priority window.

- NOfServices/ExtendedGrant have higher priority than the PWM counter.
- The PWM counter is reloaded with M and N when it reaches 1 and an arbitration decision must be made.
- The priority order is as follows:
 - Current burst service lock (assuming subsequent burst requests available when required)
 - Class 0
 - ExtendedGrant and NOfServices atomicity (assuming subsequent burst requests available when required)
 - Class 1 if PWM priority is to class 1; class 2 if PWM priority is to class 2
 - Class 2 if PWM priority is to class 1; class 1 if PWM priority is to class 2

10.2.4.1.4 Firewalls

Access permissions can be defined in the target memory address space on a per-initiator basis. Initiators are differentiated using the interconnect ConnID extension.

Permissions are allocated to the various initiators on a per-region basis. The memory regions are programmable using a start address and an end address that are defined with 64K-byte granularity. Up to seven distinct regions can be defined; the software must ensure that they do not overlap.

The remaining memory space (total memory space minus the protected areas) is defined as region 0.

Depending on whether the access is a read or a write, and depending on the in-band request qualifiers, a region may be given specific access permissions. When an access is received by the SMS, the access checked against the access attributes.

- The read permission is initiator-based and is controlled using the SMS.[SMS_RG_RDPERMi](#) register.
- The write permission is initiator-based and is controlled using the SMS.[SMS_RG_WRPERMi](#) register.
- The REQINFO bits taken into account are the incoming MReqInfo attributes: Debug, privilege, and attribute, along with the host parameter decoded in the SMS module (see the SMS.[SMS_RG_ATTi\[31:0\]](#) REQINFO field). For the SMS firewall, the host parameter is set for the MPU initiator and the sDMA initiator. The decoding of the host parameter, based on the MPU ConnID and sDMAConnID generic parameters (defined at design time), is done inside the SMS module.
- Whether the access is accepted (there is one valid bit for each ReqInfo pattern) can be specified for each ReqInfo pattern. ReqInfo permission is controlled using the region attributes register SMS.[SMS_RG_ATTi\[31:0\]](#) REQINFO field.

[Table 10-99](#) lists the ReqInfo parameters ordering.

Table 10-99. ReqInfo Parameters Ordering

Host	Privilege	Reserved for Non-GP Devices	Debug	Type	Req Info	SMS. SMS_RG_ATTi[31:0] REQINFO Field
0: Nonhost 1: Host	0: User 1: Supervisor	Reserved	0: Functional 1: Debug	0: Data Transfer 1: Opcode Fetch		
		N/A ⁽¹⁾				0b0...00000000
0	0	0	0	0	0	0b0...00000001
0	0	0	0	0	1	0b0...00000010
0	0	0	1	0	2	0b0...000000100
					...	
0	1	1	1	0	14	0b0...000001...00
0	1	1	1	1	15	0b0...00001...000
1	0	0	0	0	16	0b0...0001...0000
1	0	0	0	1	17	0b0...001...00000
					...	
1	1	1	0	1	29	0b0010...000000

⁽¹⁾ Access to the region is not allowed

Table 10-99. ReqInfo Parameters Ordering (continued)

Host	Privilege	Reserved for Non-GP Devices	Debug	Type	Req Info	SMS.SMS_RG_ATTi[31:0] REQINFO Field
0: Nonhost 1: Host	0: User 1: Supervisor	Reserved	0: Functional 1: Debug	0: Data Transfer 1: Opcode Fetch		
1	1	1	1	0	30	0b0100...000000
1	1	1	1	1	31	0b1000...000000

When all [**SMS.SMS_RG_ATTi\[31:0\]**](#) REQINFO bits are set to 0 the access to the region is not allowed.

Set the REQINFO[0] bit to 1 when NonHost-User-Functional-Data accesses are permitted in this region.

Set the REQINFO[1] bit to 1 when NonHost-User-Debug-Data accesses are permitted in this region.

Set the REQINFO[31] bit to 1 when Host-Supervisor-Debug-Opcode accesses are permitted in this region.

Any bit of the [**SMS.SMS_RG_ATTi\[31:0\]**](#) REQINFO field corresponds to a particular combination of the five attribute bits. When all [**SMS.SMS_RG_ATTi\[31:0\]**](#) REQINFO bits are set to 1 the region is full-access allowed.

The firewall unit performs the following checks to authorize or reject an access to the external memory:

- Compute the Region ID based on the transaction address.
- Generate a violation if overlapping of firewall regions is detected.
- From the Region ID, get the attributes for the region that has been hit.
- Check the transaction REQINFO attributes with respect to the region attributes (debug, privilege, type, and host).
- Reject the transaction if the attributes are not compatible.
- From the Region ID and the transaction qualifiers (MCmd, ConnID), check the initiator permissions for performing the access (read, write).
- Reject the transaction if there is no permission.

The protection regions are organized in priority levels (from Level 0 to Level 2) to prevent problems with overlapping region and corner cases associated with them; the lowest level has the lowest priority (see [Figure 10-49](#)).

Figure 10-49. Region Organization

sdrc-009

Region 0 (default region containing the whole memory space): Level 0

Region 1 (allows dynamic reprogramming of regions): Level 2

Regions 2-7 (protection regions): Level 1

Region 1 has the highest priority to perform dynamic masking of other already-programmed regions when they are reprogrammed.

Overlapping regions of the same priority level is forbidden and results in a violation when an access to the concerned region occurs. This violation is reported in the error-log register. Priority-level handling is done in the hardware; it does not involve any specific software development.

All transactions are checked, including those the RE has processed.

When detecting a violation on an incoming request, the SMS respects the response ordering within the faulty thread.

A violation flag is raised internally and the MThreadID field is logged. Generation of the interconnect error response is then local to the SMS; the response buffer must be used to manage the potential response collision with regular SDRC responses.

10.2.4.1.5 Rotation Engine

Smartphone applications must often perform image rotation between the orientation of images stored in external memory and the orientation with which they must be displayed. The device offers a hardware mechanism that allows rotation tasks to be implemented efficiently, transparent to software applications, thereby keeping the MPU and DSP CPUs free for other tasks. For a description of the RE mechanism, see [Section 10.2.6, SDRC Use Cases and Tips](#).

The SMS includes address processing support for rotated DSS displays (90, 180, and 270 degrees). This function is realized by the VRFB submodule, also called the rotation engine (RE) in this document.

The primary goal of the VRFB is to eliminate the SDRAM page-miss penalty when reading graphics data in nonnatural raster scan order (that is, top to bottom, bottom to top, right to left).

The 2D-rotation module (the VRFB) is included as a black box that intercepts incoming requests when addressed to the virtual frame buffer. If the address of the request targets the VRFB address space, the request is sent to the RE. It processes the address and reinserts the modified request in the SMS request path. The SMS translates the virtual address into physical SDRAM addresses and reinserts a request or multiple requests in the SMS request path to the SDRC.

NOTE: The use of the word *virtual* does not refer to the usual CPU-related MMU concept; the word is used in a more general context of the address remapping feature, which decouples the system from the actual storage physical organization of the graphics data in the external memory.

The VRFB can be abstracted as a 3-port module:

- Interconnect input port
- Interconnect output port
- Configuration port; all programmable control registers are part of the SMS register file, which is described in [Section 10.2.4.1.5.3, VRFB Configuration Port](#).

10.2.4.1.5.1 VRFB Input Port

The VRFB receives a 29-bit address, and two decoding signals, from the SMS module. The 29-bit address is decoded to determine the context and the rotation view of the request.

The VRFB address space is a 768-MB address space split into two non-contiguous virtual address spaces:

- Address space 0: 256 MB in quarter Q1 (start address: 0x7000 0000, end address: 0x7FFF FFFF)
- Address space 1: 512 MB in quarter Q3 (start address: 0xE000 0000, end address: 0xFFFF FFFF)

It can manage up to 12 concurrent rotation contexts. [Table 10-100](#) details the address space of each context.

Table 10-100. VRFB Contexts Virtual Address Spaces vs Rotation Angle

Context Number	0°	90°	180°	270°
0	0x7000 0000	0x7100 0000	0x7200 0000	0x7300 0000
1	0x7400 0000	0x7500 0000	0x7600 0000	0x7700 0000
2	0x7800 0000	0x7900 0000	0x7A00 0000	0x7B00 0000
3	0x7C00 0000	0x7D00 0000	0x7E00 0000	0x7F00 0000
4	0xE000 0000	0xE100 0000	0xE200 0000	0xE300 0000
5	0xE400 0000	0xE500 0000	0xE600 0000	0xE700 0000
6	0xE800 0000	0xE900 0000	0xEA00 0000	0xEB00 0000
7	0xEC00 0000	0xED00 0000	0xEE00 0000	0xEF00 0000
8	0xF000 0000	0xF100 0000	0xF200 0000	0xF300 0000
9	0xF400 0000	0xF500 0000	0xF600 0000	0xF700 0000
10	0xF800 0000	0xF900 0000	0xFA00 0000	0xFB00 0000

Table 10-100. VRFB Contexts Virtual Address Spaces vs Rotation Angle (continued)

Context Number	0°	90°	180°	270°
11	0xFC00 0000	0xFD00 0000	0xFE00 0000	0xFF00 0000

CAUTION

There is no protection in hardware for accesses outside the image resolution. Users can access the full virtual address range for a given context (there is no error reporting). Accessing outside of the image resolution creates aliasing within the image and is also translated as an additional physical memory space requirement on the external memory (some data outside of the image range can be overwritten by mistake). The following formula can be used to calculate the extra memory that will be accessed: $\text{extra_mem_size} = (2048 - \text{image_width_roundedup}) * \text{page_height} * \text{pixel_size}$ with $\text{image_width_roundedup} = \text{ROUNDUP}(\text{image_width} * \text{pixel_size}/\text{page_width}) * \text{page_width}/\text{pixel_size}$.

10.2.4.1.5.2 VRFB Output Port

The VRFB output port can be a delayed copy of the input port, with the address field transformed. Depending on the rotated view that is active, an incoming transaction can also be split into several internal transactions.

The pipeline delay between the input and the output ports is three clock periods.

10.2.4.1.5.3 VRFB Configuration Port

The configuration port allows 12 concurrent rotation settings.

The VRFB address space is a 768 MB (256 + 512) address space split into two noncontiguous spaces. It can manage up to 12 concurrent rotation settings.

The VRFB configuration port includes all the settings required to control the 12 rotation contexts. This is an input-only port. All settings are provided from the SMS control register file.

For each of the 12 contexts, the buffer physical base address, image height and width, and pixel size can be configured through the following registers (where n is the context number, from 0 to 11):

- SMS.[SMS_ROT_PHYSICAL_BAn](#)[30:0] PHYSICALBA field
- SMS.[SMS_ROT_SIZEn](#)[26:16] IMAGEHEIGHT and SMS.[SMS_ROT_SIZEn](#)[10:0] IMAGEWIDTH fields
- SMS.[SMS_ROT_CONTROLn](#)[1:0] PS field

The memory arrangement for the pixels of a frame buffer accessed through the RE is tile-based. A tile is a rectangular array of pixels. The tile size should match the page size of the SDRAM component attached to the controller for optimal performance.

The tile size is defined using the SMS.[SMS_ROT_CONTROLn](#)[10:8] page height (PH) and [6:4] page width (PW) fields.

The image height and image width (SMS.[SMS_ROT_SIZEn](#)[26:16] IMAGEHEIGHT and [10:0] IMAGEWIDTH fields, expressed in bytes) must be multiples of the tile height and width, respectively. Some padding is required if the image size does not fit this requirement.

For a configuration example, see [Section 10.2.5.1.2, VRFB Context Configuration](#).

10.2.4.1.6 Violation Reporting

The SMS firewall can detect violations and report them to the overall system by using the following qualifiers:

- The in-band error response to a non-authorized access

- The out-of-band error signal generation using two out-of-band error signals

Based on the fact that there is no way to prevent the debugger from generating firewall violations during debug, and that users cannot stop checking for functional violations, two out-of-band violation signals are set when:

- A functional violation is detected
- A debug violation is detected

These signals are asserted on each error detection from a read, write, or posted write faulty access: they are deasserted when the software clears the error bit in the [SMS_ERR_TYPE](#) register.

10.2.4.2 Module Power Saving

Power-saving is managed through the SMS.[SMS_SYSCONFIG](#) register.

The [SMS_SYSCONFIG\[4:3\]](#) SIDLEMODE field defines the power management strategy (force idle mode, no idle mode, or smart idle mode). See [Section 10.2.4.3](#) for more details about the system power management.

By default, the internal interface clock gating strategy is enabled as the [SMS_SYSCONFIG\[0\]](#) AUTOIDLE bit is set to 0x1 after reset. When all FIFO queues are empty and no ongoing transactions remain, the L3 interconnect clock is disabled inside the SMS thus reducing power consumption. The L3 interconnect clock can be disabled after a programmable delay defined in the [SMS_POW_CTRL\[7:0\]](#) IDLEDELAY bit field.

When there is new activity on the interconnect interface, the interconnect clock is restarted without any latency penalty. It is recommended to enable this mode to reduce power consumption.

There is an internal interface clock gating strategy within the SDRC. This power-saving feature is always active.

10.2.4.3 System Power Management

The SMS can be configured through the SMS.[SMS_SYSCONFIG](#) register to be in one of these idle modes:

- No-idle mode (the SMS.[SMS_SYSCONFIG\[4:3\]](#) SIDLEMODE field is set to 0x1): The module never goes into idle state.
- Force-idle mode (the SMS.[SMS_SYSCONFIG\[4:3\]](#) SIDLEMODE field is set to 0x0): The module goes into idle state immediately after receiving the request from the PRCM.
- Smart-idle mode (the SMS.[SMS_SYSCONFIG\[4:3\]](#) SIDLEMODE field is set to 0x2): SidleAck is asserted once the module has confirmed there are no more outstanding transactions with the SDRC.

10.2.4.4 SDRC

The SDRC provides two configurable memory areas. Each supports mobile SDR SDRAM and low-power DDR SDRAM from 16 Mbits to 4 Gbits, depending on the memory organization.

Flexible row/column addressing schemes are possible with 2-bank support for 16 Mbits and 32 Mbits memories, and 4-bank support for 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit, 2 Gbits, and 4 Gbits memories.

[Figure 10-50](#) shows the architecture of the SDRC.

Figure 10-50. SDRC Architecture

sdrc-010

10.2.4.4.1 CS0-CS1 Memory Spaces

10.2.4.4.1.1 Chip-Select 0 Start Address

- CS0 always starts at address 0 with respect to the local interconnect address.
- The valid CS0 range is 0 - CS0max, where CS0max is defined in the SDRC.[SDRC_MCFG_p\[17:8\]](#) RAMSIZE field where p = 0 (for CS0), and by the number of banks.

10.2.4.4.1.2 Chip-Select 1 Start Address

- CS1 start address is programmable.
- The default base address for CS1 after reset is defined in the register description.
- The SDRC 1G-byte/8G-bit address space is segmented so that 7 possible CS1 start address locations (8 in total minus 1 reserved for CS0) are defined by the SDRC.[SDRC_CS_CFG\[3:0\]](#) CS1STARTHIGH field as shown in [Figure 10-51](#).
- Each 128M-byte address space is also segmented into 32M-byte address spaces defined by the SDRC.[SDRC_CS_CFG\[9:8\]](#) CS1STARTLOW field so that 64 possible CS1 start address locations are defined by the SDRC.[SDRC_CS_CFG\[3:0\]](#) CS1STARTHIGH and SDRC.[SDRC_CS_CFG\[9:8\]](#) CS1STARTLOW fields.
- The valid CS1 range is:

CS1 start address slot - CS1max, where CS1max is defined by SDRC.[SDRC_MCFG_p\[17:8\]](#) RAMSIZE where p = 1 (for CS1) and SDRC.[SDRC_CS_CFG](#) registers.

Figure 10-51. CS0/CS1 Chip-Select Start Address Slots

sdrc-011

10.2.4.4.1.3 SDRAM Memory Combinations on CS1 and CS0

The combinations of SDR and DDR memories/SDRAMs are defined as follows:

- SDR and DDR memories can be connected on either CS1 or CS0.
- The only restriction on the coexistence of SDRAMs on CS0 or CS1 is that a combination of SDR on one CS and DDR on the other CS is not allowed.

The SDRAM data bus width on each CS is determined by the SDRC.[SDRC_SHARING\[11:9\]](#) CS0MUXCFG and SDRC.[SDRC_SHARING\[14:12\]](#) CS1MUXCFG fields of the memory-sharing registers.

10.2.4.4.2 Bank Tracking

The main state-machine controls all the accesses to external memories.

The SDRC contains hardware for tracking open pages on a per-bank basis. Up to four open pages are tracked per CS, for a maximum of eight open pages tracked.

To pipeline accesses efficiently, the SDRC includes a request look-ahead FIFO that analyzes interconnect requests with respect to the status of the target banks. A bank status can be any of the following:

- Bank open on another row
- Bank closed
- Bank open on the same row

The SDRC state-machine generates the appropriate sequence of memory commands. All precharge and active commands are hidden as much as possible, to optimize the memory bandwidth usage.

The look-ahead FIFO depth is $9 * 64$ -bit requests, with a limit of four different transactions. As soon as the look-ahead FIFO stores four complete transactions or when it is full, the SCmdAccept is deasserted and any incoming request is blocked.

Requests sent to the SDRC are treated in order. The four transactions limit in the SDRC look-ahead FIFO ensures that high-priority requests performance is not hampered by a succession of SDRAM page close/page open cycles due to previous lower priority requests already accepted by the SDRC. With this limit, requests not accepted by the SDRC will have to go through the SMS arbitration at a later time. If a high-priority request has arrived in the SMS in the mean time, it will be passed to the SDRC before any lower-priority request, as defined in the regular SMS arbitration scheme.

10.2.4.4.3 Address Multiplexing

A flexible address scheme allows for the support of any new type of SDRAM address multiplexing and density.

The programming model has changed but is still compatible with the legacy fixed address scheme. Both chips, hence both CS must use the same address scheme (fixed or flexible), but can use different address multiplexing configurations.

A dedicated bit controls the address scheme used: the legacy fixed address scheme or the new flexible address scheme:

- The legacy fixed address scheme is selected when the SDRC.[SDRC_MCFG_p\[19\]](#) ADDRMUXLEGACY bit is set to 0 (where p = 0 or 1 for SDRC CS0 or CS1).
- A new flexible address-muxing scheme configuration is selected with the SDRC.[SDRC_MCFG_p\[19\]](#) ADDRMUXLEGACY bit set to 1 (where p = 0 or 1 for SDRC CS0 or CS1).

To use this new flexible address scheme, configure the row address width and the column address with the SDRC.[SDRC_MCFG_p\[26:24\]](#) RASWIDTH and SDRC.[SDRC_MCFG_p\[22:20\]](#) CASWIDTH fields.

For more information about fixed address multiplexing configurations for SDRAM components, see [Section 10.2.2.2.3, Address Multiplexing](#).

10.2.4.4.4 Bank Allocation Setting

10.2.4.4.4.1 System Address Decoding

The SDRC has a 64-bit slave interface connected to the L3 main system interconnect. The regular allocation is to see the system address bus as the concatenation bank-row-column. The SDRC translates the interconnect request (read or write to memory for instance) into a series of commands and bank, row, column signals. The commands are sent to the external SDRAM through the sdrc_ncs, sdrc_nras, sdrc_ncas and sdrc_nwe signals. The bank, row and column addresses are sent through sdrc_a and sdrc_ba with the associated command. Those words can be defined as follow:

- Bank: the address of one of the four (or two) banks
- Row: the address of a page
- Column: the address of a word in a page

The bank signals are used to select which of the bank is accessed when transferring data from or to the SDRAM. In the first cycle, the SDRAM memory latches the row address (nRAS low): the adequate bank and row are activated. Next cycle, the SDRAM memory latches the column address (nCAS low): the adequate column is activated. The address is hence decoded: memory cells are sensed by sense amplifier and data is read from or written to output buffers.

[Figure 10-52](#) shows a block diagram of a 512 Mbits SDRAM memory (8M x 16 x 4 banks). The data bus DQ[15:0] has a 16-bit width. Rows are addressed through A0-A12 (8192 rows) and columns through A0-A9 (1024 columns).

Figure 10-52. SDRAM Controller Block Diagram

sdrc-042

10.2.4.4.4.2 SDRC Commands

Before any read or write command can be issued to a bank in the external memory, a row in that bank must be opened. This is accomplished by the active command, by which the bank and the row are selected. More than one bank (up to four according to the memory used) can be active at one time. Once a row is opened, a read or write command can be issued to that row. The row remains active until a precharge or read/write to another row in the same bank or a refresh to the bank occurs.

Autorefresh command is used during normal operation mode. This command is non-persistent (that is, it must be issued each time a refresh is required). The device requires a refresh of all rows in a periodic interval. This command takes some time (according to the memory used), and during this phase no read or write command can be processed. A precharge-all (that is, a precharge command affecting all banks) is issued before any autorefresh sequence.

An active command to a row of a bank for which another row is already active can be issued only after the previous row has been closed. The precharge command is used to deactivate the open row in a particular bank. The bank is available for a subsequent row access some time after the row precharge command is issued. A minimum time is needed to close and open a new row.

A subsequent active command to another bank can be issued while the first bank is being accessed without closing the row in the first bank. This results in a reduction of row access time in the same bank. In this case, it is not necessary to deactivate (with a precharge command) the row in the other banks. Up to four banks, depending on the memory used, can be activated at the same time. In each bank, one row can be selected at a time.

10.2.4.4.4.3 BANKALLOCATION Parameter

To optimize SDRAM memory accesses in a throughput point of view, the SDRC supports various bank-row-column allocation. The bank-row-column allocation choice depends on many parameters, such as the number of initiators in the use case, the memory usage (accesses bandwidth, frequency), and so on.

The SDRC not only supports the regular allocation where the system address bus is seen as the concatenation bank-row-column, but it also supports two other types of allocation. The **SDRC_MCFG_p[7:6]** BANKALLOCATION bit field (where p = 0 or 1 for CS0 or CS1) selects the type of allocation. This feature modifies the bank, row, and column address decoding order:

- BANKALLOCATION = 0x0: Bank-row-column
- BANKALLOCATION = 0x1: Bank1-row-bank0-column
- BANKALLOCATION = 0x2: Row-bank-column

Only the flexible address-muxing scheme allows choosing different bank mapping allocations throughout the BANKALLOCATION parameter (that is, the legacy address-muxing scheme does not).

The flexible address-muxing scheme ([SDRC_MCFG_p\[19\]](#) ADDRMUXLEGACY = 0x1) allows choosing different bank mapping allocations. The SDRC.[SDRC_MCFG_p\[7:6\]](#) BANKALLOCATION bit field (p = 0 or 1 for CS0 or CS1) defines the ordering of the bank, and the column and row decoding of the incoming system address. The BANKALLOCATION bit field can be set on a CS basis.

In the usual allocation, the system address bus is seen as a concatenation of bank-row-column. The system address received from the interconnect into the SDRC is composed of:

- 2 system address bits used as the bank address (going to SDRC sdrc_ba[1:0] pins)
- 13 system address bits used as the row address (going to SDRC sdrc_a[12:0] pins)
- 10 system address bits used as the column address (going to SDRC sdrc_a[12:0] pins)

Setting the BANKALLOCATION bit field to 0x1 or 0x2 changes the order of the system address decoding, as shown in [Figure 10-53](#).

Figure 10-53. Address Multiplexing Scheme According to BANKALLOCATION

[Figure 10-54](#) compares bank-row-column and row-bank-column memory accesses.

Figure 10-54. Simplified View of Bank-Row-Column vs Row-Bank-Column Bank Allocation

sdrc_044

The latency to charge another row in the same bank (that is, to close the opened page and to open another one) is bigger than the latency involved with an access to a given row in another bank. By moving bank select signals ahead of column and after row addresses, bank interleaving is likely to happen more often. More frequent use of the interleaved mode means less overall SDRAM access time and, thus, yields to better overall performance.

In some use cases, several initiators access the same bank (bank0 for instance) in external SDRAM memory at the same time. With this kind of scenario, a lot of penalties are added because of rows opening and closing. The BANKALLOCATION setting improves the latency for reading and writing operations by optimizing memory accesses through the reduction of deactivate sequence use, thereby reducing time penalties.

The bank1-row-bank0-column allocation is a good compromise between the legacy bank allocation (bank-row-column) and the full interleaving bank allocation (row-bank-column). In some use cases, it may be necessary to keep only half of the memory refreshed (on bank0 and bank1 for instance) while the other two banks are unused. In full interleaving bank allocation, the memory must be refreshed through the self-refresh mode, while with bank1-row-bank0-column, the memory can be refreshed through self-refresh mode or through partial array self-refresh mode.

In the following, an example of latency is given based on a 512-Mbit SDRAM memory data sheet. **Table 10-101** gives the duration for some AC timing parameters. The frequency used in the example is 133 MHz (that is, tCK = 7.5 ns). The CAS latency = 3.

Table 10-101. Mobile DDR SDRAM AC Timing Parameters

AC Timing Parameter	Description	Duration (ns)
tRFC	Autorefresh cycle time	80 (min)
tRP	Row precharge time	22.5 (or 3 tCK)

Table 10-101. Mobile DDR SDRAM AC Timing Parameters (continued)

AC Timing Parameter	Description	Duration (ns)
tRC	Row cycle time	67.5 (or 9 tCK)
tRAS	Row active time	45 (or 6 tCK)
tRCD	nRAS to nCAS delay time	22.5 (or 3 tCK)
tRRD	Row active to row active delay time	15 (or 2 tCK)

The latency to access another row in the same bank depends on tRP and tRAS timings because a precharge command followed by an active command must be issued. Therefore, 6 tCK are needed to close the current row and open another one.

When accessing another bank, the latency to access another row depends on tRAS timing only because the closing of the current row is not mandatory. In other words only an active command must be issued. Therefore, 3 tCK are needed to open another row in a different bank.

Single initiator use case:

When the initiator wants to access a page in a bank for the first time, it opens only this page. It takes 3 tCK. When the initiator is done with this page, it closes this page and opens another one. It takes 6 tCK.

Two initiators use case:

When one initiator wants to access a page in the same bank, it must necessarily close the current page and open the page it wants to access. It takes 6 tCK.

When one initiator wants to access a page this time in another bank, there can be less page opening and closing. For instance, if the initiator wants to open a page in another bank where no page is open, it takes only 3 tCK, rather than 6 tCK if it was another page in the same bank.

10.2.4.4.5 Data Multiplexing During Write Operations

10.2.4.4.5.1 External Bus Combinations

The SDRC pin allocation scenarios are provided in [Table 10-102](#). These scenarios are defined on a per-CS basis for maximum flexibility. The pin allocation configurations allow implementation of combinations of the 16-/32-bit external interfaces listed in this table. The data multiplexer receives a 64-bit word from the SDRAM command queue and partitions the data into a series of 16-bit or 32-bit accesses. The data multiplexer also steers the data to the appropriate data lane. The data partitioning and data steering are determined by the SDRC.[SDRC_SHARING\[11:9\]](#) CS0MUXCFG and SDRC.[SDRC_SHARING\[14:12\]](#) CS1MUXCFG fields.

Table 10-102. SDRC Data Lane Configurations

Device pins	sdrc_d[31:24]	sdrc_d[23:16]	sdrc_d[15:8]	sdrc_d[7:0]	
	DataLane[31:16]				DataLane[15:0]
	DQS3	DQS2	DQS1	DQS0	
	DQM3	DQM2	DQM1	DQM0	SDRC. SDRC_SHARING[14:9] CSnMUXCFG field
	D[31:0]				0x0, 0x1
	D[15:0]				0x2, 0x7
			D[15:0]		0x3
					0x4, 0x5, 0x6: Reserved

10.2.4.4.5.2 Endianness-Aware Unpacking

Data transactions can be either big or little endian; the transaction endianness is determined by an in-band interconnect qualifier. Muxing 64-bit data to 16-/32-bit data is performed according to this qualifier.

For a 64-bit interconnect little-endian write transaction on a 16-/32-bit memory, Data[15(31):0] is written at the lowest memory address, and Data[63:48(32)] is written at the highest memory address.

For a 64-bit interconnect big-endian write transaction on a 16-/32-bit memory, Data[15(31):0] is written at the highest memory address, and Data[63:48(32)] is written at the lowest memory address.

Figure 10-55 shows the data multiplexing scheme.

Figure 10-55. Data Multiplexing Scheme

sdrc-012

10.2.4.4.6 Data Demultiplexing During Read Operations

10.2.4.4.6.1 External Bus Combinations

The SDRC pin allocation scenarios are shown in [Table 10-102](#). These scenarios are defined on a per-CS basis for maximum flexibility. The pin allocation configurations allow implementation of combinations of 16-/32-bit external interfaces. The data demultiplexer receives 16-/32-bit data from the relevant SDRC data lane, and then performs a data packing function. The packing function formats the data into 64-, 32-, 16-, or 8-bit format. The data demultiplexer also steers the data from the appropriate data lane. The data partitioning and data steering are determined by the SDRC.[SDRC_SHARING\[11:9\]](#) CSOMUXCFG and SDRC.[SDRC_SHARING\[14:12\]](#) CS1MUXCFG bit fields.

Figure 10-56 shows the data demultiplexing scheme.

Figure 10-56. Data Demultiplexing Scheme

10.2.4.4.6.2 Endianness-Aware Packing

Data transactions can be big or little endian; their endianness is determined by an in-band interconnect qualifier. Demuxing 16-/32-bit memory data to 64-bit interconnect data is performed according to this qualifier.

For a 64-bit interconnect little-endian read transaction on a 16-/32-bit memory, Data[15(31):0] is read from the lowest memory address, and Data[63:48(32)] is read from the highest memory address.

For a 64-bit interconnect big-endian read transaction on a 16-/32-bit memory, Data[15(31):0] is read from the highest memory address, and Data[63:48(32)] is read from the lowest memory address.

To preserve data integrity in all situations, that is, regardless of the effective scalar size of the transferred data (byte, Word16, Word32, or DWord64), the endianness specified during the read operation must match that specified during the write operation. If there is no match, the packing and unpacking operations are not consistent. There is no attempt to perform endianness conversion in the SDRC; only endian-aware width conversion is performed.

10.2.4.4.7 Refresh Management

Refresh management can be divided as follows:

- Self-refresh management
- Autorefresh management (programmable refresh period)

10.2.4.4.7.1 Self-Refresh Management

Self-refresh is entered to place an attached SDRAM into an autonomous refresh mode, typically when the device enters an idle mode and switches off the SDRAM clock.

In self-refresh, the SDRAM supplies the row address generation required to refresh and retain data in the absence of external clocking.

Self-refresh can be entered using any of the following methods:

- Manually, under software control per CS
- Upon a reset event: Automatically on a warm reset event (if the SDRC is programmed to enter self-refresh on warm reset)
- Upon a hardware request: Automatically on an idle request sent by the system power manager (if the SDRC is programmed to enter self-refresh on idle request)
- Automatically after a (programmable) period of inactivity on the interconnect interface (if enabled by setting the SDRC.[SDRC_POWER_REG\[5:4\]](#) CLKCTRL bit field to 0x2)

Self-refresh can be exited as follows:

- Manual software command (exit from self-refresh mode; see [Section 10.2.5.3.4, DLL/CDL Configuration](#))
- Automatically after receiving a read or write transaction to access memory

10.2.4.4.7.2 Autorefresh Management

When autorefresh is enabled, a programmable hardware counter within the SDRC generates a periodic event that triggers either a single refresh or a burst of consecutive refresh commands. This is the standard refresh mode used when the system is active, while the running applications regularly access the SDRAM.

An autorefresh command can also be applied using the SDRC.[SDRC_MANUAL_p](#) register (see [Section 10.2.5.3.4, DLL/CDL Configuration](#)). This method can be used to generate a device-specific initialization sequence after power up or after the memory device exits from a low-power mode (self-refresh or deep-power-down).

The autorefresh request period is a user-controlled parameter programmed to meet the specification of the memory devices. Each time an autorefresh request is issued, the SDRC can service the autorefresh using any of the following commands:

- Single autorefresh command
- Burst of four autorefresh commands
- Burst of eight autorefresh commands

When a burst of four or eight is selected, the programmed period value is automatically scaled in hardware by 4 or 8. Consequently, the value to be programmed does not depend on the selected burst length.

10.2.4.4.8 System Power Management

Unlike the SMS, the SDRC can be configured only in smart-idle mode by setting the SDRC.[SDRC_SYSConfig\[4:3\]](#) IDLEMODE field to 0x2. Once all asserted output interrupts are acknowledged, the SDRC goes into idle state after it receives the request from the PRCM module.

The SDRC acknowledge is conditioned by the internal activity of the SDRC.

NOTE: As soon as the SDRC goes out of idle state, stalled accesses can be accepted and processed:

- In SDR mode, the access can be immediately processed (unstalled).
- In DDR fixed delay mode, the access is processed (unstalled) after expiration of MODEFIXEDDELAYINITLAT.

10.2.4.4.9 Power-Saving Features

In the SDRC there are three ways to save power and they can be applied simultaneously:

- Page opening/closure policy
- Dynamic low-power mode
- Static low-power mode

10.2.4.4.9.1 Page Opening/Closure Policy

The device supports only one page policy. The SDRC.[SDRC_POWER_REG\[0\]](#) PAGEPOLICY bit must be set to 1.

The SDRC tracks open pages, if any, and determines whether the current access is to an open or a closed page. If the accessed page is open, the SDRC executes the access immediately. The SDRC performs the following procedure:

1. If the current page is already open on this bank the SDRC automatically issues a *precharge* command to close that bank.
2. Opens the accessed page by issuing an *active* command to that bank
3. Executes the access by issuing a *read* or *write* command

Up to four pages can be open simultaneously with a limit of one page per bank. The pages remain open until one of the following occurs:

- New read or write request to another page in the same bank
- Autorefresh request (a *precharge all* command is issued first)
- Self-refresh entry request (a *precharge all* command is issued first)
- Manual *precharge all* command

10.2.4.4.9.2 Dynamic Low-Power Operating Modes

The dynamic low-power operating modes of the SDRC are designed to:

- Control the external SDRAM clock(s)
- Control the internal clock gating of the SDRC when the interconnect interface is idle
- Control the self-refresh functionality

The external SDRAM is controlled through the SDRC.[SDRC_POWER_REG\[3\]](#) EXTCLKDIS and SDRC.[SDRC_POWER_REG\[2\]](#) PWDENA bits. The EXTCLKDIS bit is used to disable the external clock when no access is ongoing on the memory interface, whereas the PWDENA bit is used to activate the power-down mode of the target memory by pulling the relevant CKE low each time the memory interface is idle.

When the PWDENA bit is enabled but the EXTCLKDIS bit is not enabled, the SDRC still provides a free-running clock to the external memories: clock gating is done internal to the memory component for power savings.

EXTCLKDIS should be modified only when no access is in progress on the SDRAM interface. Software control is required to make sure the interface is idle.

CKE is dynamically controlled based on the current memory command. There is a zero-latency penalty when this mode is enabled.

The SDRC has three modes of automatic internal clock-gating behavior when the interconnect interface is idle, that is, there are no outstanding active transactions in progress. These modes are controlled through the SDRC.[SDRC_POWER_REG\[5:4\]](#) CLKCTRL and SDRC.[SDRC_POWER_REG\[23:8\]](#) AUTOCOUNT fields.

- Mode 0: The autoclock gating feature is disabled. No internal clock gating is performed in the SDRC in response to the detection of an idle state on the interconnect interface.
- Mode 1: A 16-bit counter starts decrementing when an interconnect idle condition is detected. The counter start value is loaded from the AUTOCOUNT 16-bit field. When this counter times out, internal clock gating within the SDRC is enabled.
- If an interconnect active command is received before the counter times out, or if an internal autorefresh request is issued, the procedure is aborted, the counter stops decrementing, and the request is serviced immediately.
- Mode 2: This mode is similar to mode 1, but before the internal clock gating, the SDRC places the SDRAM into self-refresh mode and turns off the external SDRAM clock. This is the lowest power mode.

To achieve maximum power savings, TI recommends the use of the PWDENA-, EXTCLKDIS-, and CLKCTRL-related features.

[Table 10-103](#) explains the different power-saving configurations that can be programmed with the SDRC.[SDRC_POWER_REG\[3\]](#) EXTCLKDIS, SDRC.[SDRC_POWER_REG\[2\]](#) PWDENA, and SDRC.[SDRC_POWER_REG\[5:4\]](#) CLKCTRL bits.

Table 10-103. Dynamic Power Saving Configurations

CLKCTRL	EXTCLKDIS	PWDENA	CKE	External SDRC CLK ⁽¹⁾	SDRAM State	Latency When Exiting Power Mode
0	0	0	Always high	Always on	Keep previous state	
0	0	1	Low when no access	Always on	Power-down	Zero-latency penalty
0	1	0	Always high	Off when no access	Keep previous state	
0	1	1	Low when no access	Off when no access	Power-down	One cycle penalty
1	0	0	Always high	Always on	Keep previous state	
1	0	1	Low when no access	Always on	Power-down	Zero-latency penalty
1	1	0	Always high	Off when no access	Keep previous state	
1	1	1	Low when no access	Off when no access	Power-down	One cycle penalty
2	0	0	Low when no access	Off when no access after AUTOCOUNT expiration	Enter self-refresh after AUTOCOUNT expiration	
2	0	1	Low when no access	Off when no access after AUTOCOUNT expiration	Enter self-refresh after AUTOCOUNT expiration	
2	1	0	Low when no access	Off when no access	Enter self-refresh after AUTOCOUNT expiration	
2	1	1	Low when no access	Off when no access	Enter self-refresh after AUTOCOUNT expiration	

⁽¹⁾ EXTCLK can be set to 1 all the time for power optimization purposes, except when manual commands are sent. In this case, users must set EXTCLKDIS to 0 to ensure that a clock signal is provided to the memory device.

NOTE: When connected to a DDR memory, the SDRC never gates the clock provided to the DLL components so that the DLL remains locked during these idle modes. This avoids the maximum of 500 clock cycles latency required for relocking the DLL when the DLL clock is switched off.

All settings for the power-saving features are common to the two CSs. When two CSs are used, however, only the accessed CS exits self-refresh or deep-power-down mode.

If the SDRC.[SDRC_POWER_REG](#)[6] SRFRONIDLEREQ bit is enabled, the SDRC enters self-refresh mode on a hardware idle request from the PRCM. The memory clock is automatically switched off, after which the SDRC sends an acknowledge back to the PRCM. In this situation, the power manager can switch the SDRC clock off. Therefore, if the SDRC is connected to a DDR memory, and if the DLL is enabled and in TrackingDelay mode, the SDRC waits for the lock status bit of the DLL to be asserted before accessing the memory when the system exits the idle state. The WAKEUPPROC bit of the [SDRC_POWER_REG](#) register enables the SDRC to automatically wait for 500 cycles (DLL relocking maximum time) before accessing the memory instead of using the LOCK signal. These 500 wait cycles are obeyed only when the DLL is set in TrackingDelay mode. For SDR mode and DLL ModeFixedDelay mode, the access is processed immediately. This mechanism is independent of the CLKCTRL field.

NOTE: DLL Behavior Upon a Warm Reset Assertion:

Upon a warm reset (the [SDRC_DLLA_CTRL](#)[3] ENADLL bit is not reset as it is not sensitive to warm reset but the DLL will be in unlock mode since DLL is reset. To lock the DLL again, the [SDRC_DLLA_CTRL](#)[3] ENADLL needs to be made 0 and then made 1 again. This will trigger a locking sequence.

10.2.4.4.9.3 Static Low-Power Operating Modes

The software-driven controls for low-power operation modes include:

- Possibility to put the memory in self-refresh using the manual command register ([SDRC_SDRC_MANUAL_p](#) (where p = 0 or 1 for SDRC CS0 or CS1). Each CS can be controlled independently. If both CSs are in self-refresh, the external SDRAM clock can be switched off by setting the SDRC.[SDRC_POWER_REG](#)[3] EXTCLKDIS control bit to 1. Self-refresh can be exited automatically if an access is initiated onto the CS. Only DPD must be exited manually.
- Possibility to put the memory in deep-power-down mode, if supported by the SDRAM, using the manual command register. Each CS can be controlled independently. The external SDRAM clock can be switched off if both CSs are either in self-refresh or deep-power-down mode by setting the SDRC.[SDRC_POWER_REG](#)[3] EXTCLKDIS control bit to 1. Another manual command must be used for the memory to exit deep-power-down mode. After a memory exits from that mode all data are lost, and a full initialization sequence must be sent to the device, before it can be used.

10.2.4.4.10 SDRC Power-Down Mode

In some applications, the SDRC power domain can be powered down while the external memory is in self-refresh mode.

When the SDRC is powered off, an isolation stage prevents an unwanted exit from self-refresh when the context is restored. SDRC outputs that control the SDRAM are set to maintain self-refresh or deep-power-down (CKE low).

When a reset occurs, the default reset state of the SDRC is power-down enable (PDE).

When exiting the off mode:

- Power is restored to the SDRC.
- The software reconfigures all registers. If the NOMEMORYMRS bit is set, the MR and EMR registers can be set through the SDRC.[SDRC_MR_p](#) and SDRC.[SDRC_EMR2_p](#) registers (see [Section 10.2.4.5, Mode Registers](#)).
- Exit from self-refresh mode is achieved through the SDRC.[SDRC_MANUAL_p](#) CMDCODE field. Because exit from the self-refresh field is unconditional (that is, the current state of the SDRC state-machine is not considered), ensure that autorefresh is disabled.

Once the context is successfully restored, the software can reinitialize the SDRAM or return the SDRAM to self-refresh. When the device successfully exits self-refresh, autorefresh must be re-enabled.

10.2.4.4.11 Controlled Delay Line

The DLL/CDL module is a hard macro composed of one master delay-locked loop (DLL) and five slave-controlled delay lines (CDL). It is used to generate precise delays suitable for DDR read and write operations. DLL delays are tracked at high frequency on process dispersion, and voltage and temperature variations (PVT).

A CDL is a component with a clock input signal, a clock output signal, and a delay value input. The output signal is the input signal delayed according to the delay value.

The DLL output is a command that controls the CDLs (plus the controlled voltage) and assures an output signal with 90-degree delay with respect to its input signal. The DLL contains five CDL blocks.

10.2.4.4.11.1 Purpose of the DLL/CDL Module

In DDR applications, the DLL and CDL combination helps provide a data strobe (DQS) with a delay suitable to the main read and write RAM operations that exceed 83 MHz. The DLL functions within a locking range of 83 to 200 MHz. Below 83 MHz, the DLL must be used in unlocked mode. For lower clock frequencies, set the DLL to bypass mode.

DLL/CDL is used to delay the incoming DQS in case of DDR read, or delay the output DQ (data lines) in case of DDR write (and, hence, to increase the ac timing margin). DQS is used only with DDR memory. There is no need to use the DLL/CDL for the SDR DRAM because data is strobed every clock cycle. The DQS signals are left unconnected for SDR SDRAM memories.

DQS is propagated with the data (thus reducing the impact of the propagation delay) and is used by the receiver to sample the data.

The DLL/CDL combination minimizes the negative effects caused by skews and jitters of clock signals. The delay introduced by the CDL base unit depends on PVT conditions. Moreover, the CDL timing delay is not a linear function of the DLL counter offset. By means of the DLL feedback loop, the delay value is updated in real time and is adjusted according to voltage and temperature variations.

DDR interfaces transmit data on both edges of the DQS bidirectional data strobe. Address and control signals transmit at half the data frequency (that is, at the DDR clock frequency) and latch only on the rising edge of the transmit clock.

The bidirectional data strobe (DQS) is transmitted externally, along with data, for use in data capture at the receiver. `sdrc_dqs[3:0]` is an SDRC I/O that connects the SDRC with DDR SDRAM DQS pins. See [Figure 10-43](#) for an overview of DDR SDRAM connection with the SDRC. DQS is transmitted by the DDR SDRAM during reads and by the SDRC during writes. DQS is edge-aligned with data for reads and center-aligned with data for writes, as shown in [Figure 10-57](#).

[Figure 10-57](#) shows the generic DDR data-write and data-read waveforms.

Figure 10-57. Generic DDR Data-Write and Data-Read Waveforms

sdrc-014

Figure 10-58 shows the DDR SDRAM data and data strobe DQS signals exiting synchronously and in phase during a data read. DQS signals are used to sample incoming data internally and, hence, must be delayed to create data-setup and data-hold time at the synchronization flip-flop inputs, as shown in the bottom waveform of Figure 10-58. This is the goal of the DLL/CDL module.

Figure 10-58. Required Synchronization DFF Input Signals

sdrc-015

10.2.4.4.11.2 DLL/CDL Module Architecture

Figure 10-59 shows how the DLL/CDL interacts with the synchronization flip-flops. See Table 10-102 for more information on device pins and SDRC data-lane configurations regarding DQS.

Figure 10-59. DLL/CDL Architecture

sdrc-016

Figure 10-60 shows a simplified block diagram of the DLL/CDL module.

Figure 10-60. Simplified DLL/CDL Block Diagram

sdrc-017

The DLL circuit contains four delay elements in series. Therefore, the DLL output code and regulator output voltage determine a delay equivalent to one fourth of the reference input period in a stand-alone DLL/CDL (those CDLs are delay elements integrated into the DLL and are not shown in Figure 10-59). In other words, the DLL/CDL delay is equivalent to 90 degrees without DLL/DCDL.

10.2.4.5 Mode Registers

10.2.4.5.1 Mode Register (MR)

This register is common to all SDR and DDR SDRAMs. It is a 12-bit register and controls the following parameters:

- Write burst mode (SDRC.**SDRC_MR_p[9]** WBST bit (where p = 0 or 1 for SDRC CS0 or CS1)
- CAS latency (SDRC.**SDRC_MR_p[6:4]** CASL field)
- Serial/interleaved mode (SDRC.**SDRC_MR_p[3]** SIL bit)
- Burst length (SDRC.**SDRC_MR_p[2:0]** BL field)

MR is accessible through SDRC.**SDRC_MR_p** (where p = 0 or 1 for SDRC CS0 or CS1). Writing to SDRC.**SDRC_MR_p** initiates an implicit load mode register command qualified by BA1, BA0 = 0, 0.

10.2.4.5.2 Extended Mode Register 2 (EMR2)

This register is specific to low-power SDR and mobile DDR SDRAM devices. It is a 12-bit register and controls the following parameters:

- Temperature-compensated self-refresh (SDRC.**SDRC_EMR2_p[4:3]** TCSR field)
- Partial array self-refresh (SDRC.**SDRC_EMR2_p[2:0]** PASR field)

EMR2 is accessible through SDRC.**SDRC_EMR2_p** (where p stands for CS0 or CS1). Writing to SDRC.**SDRC_EMR2_p** initiates an implicit load mode register command qualified by BA1, BA0 = 1, 0.

NOTE: PASR Setting Before Entering Self-Refresh Mode:

Partial array self-refresh (PASR) allows memory accesses to all banks when the attached memory is not in self-refresh. Software must ensure that after a self-refresh mode with PASR field enabled on banks, only accesses to the refreshed parts of the memory are performed. Failure to do so may result in fetching corrupted data.

10.2.5 SDRC Subsystem Basic Programming Model

This section contains programming guides on setting up the SMS and SDRC registers according to the required application.

10.2.5.1 SMS Basic Programming Model

10.2.5.1.1 SMS Firewall Usage

Because region 0 always has level 0 priority, it can be masked by any protected region.

To configure a region:

1. Set the SMS.[SMS_RG_ATTi](#) register (where i is the region index from 0 to 7).
2. Set the SMS.[SMS_RG_RDPERMi](#) register.
3. Set the SMS.[SMS_RG_WRPERMi](#) register.
4. Set the SMS.[SMS_RG_STARTj](#) register (except for region 0. j is the region index from 1 to 7).
5. Set the SMS.[SMS_RG_ENDj](#) register (except for region 0. j is the region index from 1 to 7).

Region 0 is always active. There are no start and an end address for region 0. As soon as the SMS.[SMS_RG_STARTj\[30:16\]](#) STARTADDRESS and SMS.[SMS_RG_ENDj\[30:16\]](#) ENDADDRESS registers (where j = 1 to 7) are programmed, the firewall is activated. To prevent unexpected violations, ensure that the protection regions do not overlap.

Region 1 ensures the proper dynamic programming of protection for regions 2 through 7. For example, the protected region A is set and currently accessed, but it must be enlarged. To avoid deactivating region A and exposing its content to unwanted leakage, region 1 can be used to mask this whole area during reprogramming. When region A is correctly reprogrammed, region 1 can be deactivated.

When all the required regions are programmed, the locking mechanism allows freezing the configuration, thus ensuring no further reprogramming.

10.2.5.1.2 VRFB Context Configuration

Using the RE requires several initialization programming steps. After an RE context is set up, an application can use it transparently, as if addressing a frame buffer object with a standard raster-based memory arrangement.

1. Define the page configuration. This operation usually depends only on the external memory device. The same page settings are then applied to any newly created rotated frame buffer.
Consider an SDRAM device with 1024-byte pages. The page can be defined as a 16 * 64 array. The page is not necessarily a square (32 * 32 is also a suitable value). It is recommended that the longest side corresponds to the access direction requiring the maximum bandwidth.

In terms of register settings, in any context that uses that page size:

Page (page) width = 2^{pw} bytes (that is, pw = 6)

Page (page) height = 2^{ph} rows (that is, ph = 4)

2. The application must allocate the appropriate amount of memory in the SDRAM address space, as required by the size of the frame buffer object.

Example: Create a 400 x 300 frame buffer, 16 bits per pixel

- Pixel size = 2^{ps} bytes (that is ps = 1)
- Number of pages per line: $400 * 2/64 = 12.5$, rounded up to 13
- Number of pages per column: $300/16 = 18.75$, rounded up to 19

In terms of register settings, the image size parameters correspond to the enlarged image, and are programmed to:

- Image width = w pixels (that is, $w = 13 * 64 / 2 = 416$)
- Image height = h pixels (that is, $h = 19 * 16 = 304$)

NOTE: In this example, the values obtained are not integer values, but are rounded up to the closest integer value. This results in a loss of physical memory, generally negligible compared to the total size of the image.

In terms of memory allocation (in the physical memory), this corresponds to a $416 * 304 * 2 = 252,928$ -byte buffer.

The physical base address of this buffer must be aligned on a page boundary (in that example, a 1024-byte boundary; that is, the 10 LSBs of the base address must be all zeros). This buffer must be allocated as a contiguous memory segment.

All these parameters, once determined, must be loaded in the registers of the chosen context (there are 12 VRFB contexts with 12 independent sets of registers).

Example, context 1:

- Configure the physical base address of the frame buffer. Example: 512M bytes, start of CS0, SMS.[SMS_ROT_PHYSICAL_BAn](#)[30:0] PHYSICALBA = 0x20000000 (where n = 1)
 - Configure the image height and width:
Image width (416): SMS.[SMS_ROT_SIZEn](#)[10:0] IMAGEWIDTH = 0x1A0 (where n = 1)
Image height (304): SMS.[SMS_ROT_SIZEn](#)[26:16] IMAGEHEIGHT = 0x130
 - Configure the control parameters:
Pixel size (example: 2 bytes, 2^1 bytes): SMS.[SMS_ROT_CONTROLn](#)[1:0] PS = 0x1 (where n = 1)
Page (page) size (example: 1024 bytes = 64 bytes * 16 bytes)
Page height (example: 16 rows, 2^4 rows): SMS.[SMS_ROT_CONTROLn](#)[10:8] PH = 0x4
Page width (example: 64 bytes, 2^6 bytes): SMS.[SMS_ROT_CONTROLn](#)[6:4] PW = 0x6
3. The frame buffer just created is now ready for use by the different system initiators (MPU, sDMA, DSS controller, etc.).

From the perspective of these modules, the frame buffer object can be accessed at the following VRFB address-space memory locations:

- Context 1 0-degree view: 0x7400 0000
- Context 1 90-degree view: 0x7500 0000
- Context 1 180-degree view: 0x7600 0000
- Context 1 270-degree view: 0x7700 0000

The start address of the view corresponds to the logical origin of the image ($x = 0, y = 0$). The image pitch parameter, commonly defined as the distance between two vertically adjacent pixels, is fixed to 2048 pixels.

Example of usage by the application:

In a system using an 400 * 300 LCD panel that has a native landscape orientation, the natural scan order is as shown in [Figure 10-61](#).

Figure 10-61. Natural Scan Order

sdrc-018

The display buffer is the one created in the example sequence.

When the application is running and uses the portrait orientation for the display (typically, a PDA-type application):

- The DSS controller accesses the frame buffer using the 0-degree view.
- The processor and other initiators, such as 2D DMA or 3D accelerators, use the 90-degree view.

When the application is running and uses the landscape orientation for the display (typically, a video recorder/player or gaming application):

- The DSS controller still accesses the frame buffer using the 0-degree view.
- The processor and other initiators, such as 2D DMA or 3D accelerators, also use the 0-degree view. See [Section 10.2.6.1.1](#).

10.2.5.1.3 Memory-Access Scheduler Configuration

The memory-access scheduler is configured as follows:

- For each of the three classes, the arbitration parameters are:
 - SMS.[SMS_CLASS_ARBITER0](#) through SMS.[SMS_CLASS_ARBITER2](#)
 - One high-priority FIFO queue in the class (HIGHPRIVECTOR field)
 - Number of consecutive transactions to perform (EXTENDEDGRANT field)
 - Burst transaction submitted for arbitration immediately or after the burst has been buffered (BURST-COMPLETE field)

10.2.5.1.4 Error Logging

All data transfers in the SMS are full handshake. The SMS uses this capability to signal the system when a transaction error is detected.

The SMS captures the address of the faulty access in the SMS.[SMS_ERR_ADDR](#) register. The error type is logged in the SMS.[SMS_ERR_TYPE](#) register. Once a faulty access is logged and the SMS.[SMS_ERR_TYPE\[0\]](#) ERRORVALID bit is set, the next faulty accesses cannot be logged before clearing the ERRORVALID bit.

In the case of an interconnect transaction, an error response is generated if any of the following occur:

- An incoming request arrives after an idle request from the PRCM.
- An illegal command is received.
- A protection region overlap is detected.
- Protection errors.

It is assumed that the system interconnect on which the SMS is plugged is responsible for signaling the error event to the host MPU based on the interconnect response. The MPU error handler can then consult the error logging registers.

10.2.5.2 SDRC Configuration

10.2.5.2.1 IP Revision

The IP revision code can be read in the SDRC.[SDRC_REVISION\[7:0\]](#) REV field.

10.2.5.2.2 Reset Behavior

The reset behavior of the SDRC can be classified into three subgroups:

- Asynchronous cold-reset (power-on reset) behavior
- Asynchronous warm reset behavior
- Synchronous soft-reset behavior

When the system-wide power-on reset is applied through cold reset, all flops are reset to their default values, and all state-machines are returned to their idle states.

The programming model for data recovery following a warm reset is as follows:

- Program the SDRC.[SDRC_POWER_REG](#) register to enable the SDRC.[SDRC_POWER_REG\[7\]](#) SRFRONRESET bit.

A warm reset condition is then issued.

- The SDRC enters self-refresh mode since the SRFRONRESET bit is set.
- The SDRC does not execute global SDRC reset since the reset is not qualified as cold.
- The SDRC state-machine maintains the external memory device in self-refresh.

The first SDRC access to the configuration register must then be:

1. Check the SDRC configuration.
2. Exit self-refresh mode using the manual command register.

A software-controlled reset is also available by using the SDRC.[SDRC_SYSConfig\[1\]](#) SOFTRESET bit (set this bit to 1 to activate the reset). The completion of the reset can be determined by reading the SDRC.[SDRC_SYSSTATUS\[0\]](#) RESETDONE bit.

When the SDRC is reset due to the presence of either a soft or cold reset, all SDRC flops are reset.

NOTE: SDRC Requirement at First Power-Up to Have sdrc_cke Pin High

To comply with the JEDEC standard, sdrc_cke pins values are forced to 1 during the initial memory power-up phase: software must ensure that sdrc_cke pin is released after the initialization phase; it happens only at first power-up (on a cold reset). Thus, at the end of the initial SDRC power-up sequence and before programing the PWDENA field, software must ensure that the sdrc_cke pin is driven by the SDRC module. Then the value of the PWDENA field can be modified. See [Section 10.2.5.4.1](#) for more details on sdrc_cke driving.

NOTE: Set the INPUTENABLE0 bit of CONTROL.CONTROL_PADCONF_SDRC_CLK to assure the synchronization of sdrc_clk. For more information, see [Chapter 13, System Control Module](#).

10.2.5.3 SDRC Setup

A number of device parameters must be set before executing the initialization sequence.

10.2.5.3.1 Chip-Select Configuration

CS0 always starts at 0x8000 0000 (with respect to the 32-bit interconnect address). There is no restriction on the presence of any SDRAM on CS0 or CS1.

The total address space of the SDRC is 1G byte/8G bits. The total address space is divided into 8 * 128M-byte partitions as shown in [Figure 10-51](#). Each partition is a possible start address for CS1, except for the partition occupied by CS0.

The start address for CS1 is defined by the SDRC.[SDRC_CS_CFG\[9:8\]](#) CS1STARTLOW and SDRC.[SDRC_CS_CFG\[3:0\]](#) CS1STARTHIGH fields.

Space 0, selected by the SDRC using the CS0 (nCS0) output pin, is always at offset 0 from the SDRAM memory space base address. The size of this area is programmable through the SDRC.[SDRC_MCFG_p\[17:8\]](#) RAMSIZE field, where p = 0. Space 1, selected by the SDRC using the CS1 (nCS1) output pin, is at an offset from the SDRAM memory space base address; this offset is programmable in 128M-byte increments. The size of this area is programmable through the SDRC.[SDRC_MCFG_p\[17:8\]](#) RAMSIZE field, where p = 1. The type of device for each area is programmable through the SDRC.[SDRC_MCFG_p](#) register (where p = 0 or 1 for SDRC CS0 or CS1).

NOTE: Ensure that space 0 and space 1 do not overlap each other or extend farther than the maximum 1G-byte SDRC memory space, as explained in [Section 2.2, Global Memory Space Mapping](#), of [Chapter 2, Memory Mapping](#).

10.2.5.3.2 Memory Configuration

The memory configuration is defined on a per-CS basis through the SDRC.[SDRC_MCFG_p](#) register (where p = 0 or 1 for SDRC CS0 or CS1).

[Table 10-104](#) lists the memory configuration.

Table 10-104. Memory Configuration

Bit Field	Comments
ADDRMUXLEGACY	Address multiplexing scheme
RAMSIZE	Defines the physical RAM address space in terms of 2M -byte chunks
B32NOT16	External device data bus width.
DEEPPD	Set this bit if the memory supports deep-power-down mode. (This bit is only a flag for software. It does not affect any SDRC function.)
DDRTYPE	Mobile DDR
RAMTYPE	Single Data Rate or Double Data Rate SDRAM

NOTE: Exported Register Reset Values and Lock Bit

The reset values of SDRC.[SDRC_MCFG_p](#) and SDRC.[SDRC_SHARING](#) are exported in the control module. At reset, these registers take the value previously stored in the control module. A new bit is added to each register to provide the capability to lock these three registers into read-only accesses:

- SDRC.[SDRC_MCFG_p\[30\]](#) LOCKSTATUS bit (p = 0 or 1 for CS0 or CS1)
- SDRC.[SDRC_SHARING\[30\]](#) LOCK bit

The reset value of each lock bit is also imported from the control module.

10.2.5.3.3 SDRAM AC Timing Parameters

The AC parameters described in [Table 10-105](#) can be independently programmed (standard JEDEC LPDDR1 terminology is used here) in clock cycles for each of the two memory areas through registers SDRC.[SDRC_ACTIM_CTRLA_p](#) and SDRC.[SDRC_ACTIM_CTRLB_p](#) (p = 0 or 1, depending on the CS area).

Table 10-105. Programmable AC Parameters

SDRC AC Parameter	Description	Range (Clock Ticks)
tRFC	AUTO REFRESH to ACTIVE / AUTO REFRESH command period (autoReFresh Cycle time)	0 - 31
tRC	ACTIVE to ACTIVE command period (Row Cycle time)	0 - 31
tRAS	ACTIVE to PRECHARGE command period	0 - 15
tRP	PRECHARGE command period (Row Precharge time)	0 - 7
tRCD	ACTIVE to READ or WRITE delay (Row-to-Column Delay time)	0 - 7
tRRD	ACTIVE bank A to ACTIVE bank B delay	0 - 7
tWR	WRITE Recovery time (also known as tDPL)	0 - 7
tDAL	Auto precharge write recovery + precharge time	0 - 31
tWTR	Internal Write to Read command delay (also known as tCDLR)	1 - 3
tCKE	CKE min pulse width (high and low pulse width)	1 - 7
tXP	Exit Power-Down to next valid command delay	1 - 7
tXSR	Self-Refresh exit to next valid command delay	0 - 255

Example of configuration:

If there is a minimum tRC requirement of 88 ns at 100 MHz, $88/10 = 9$ (8.8 is rounded up). Therefore, nine clock cycles must be set.

The SDRC AC parameters described in [Table 10-106](#) are hard-coded.

Table 10-106. Nonprogrammable AC Parameters

SDRC AC Parameter	Description	Range (Clock Ticks)	Comment
tMRD	MODE REGISTER SET command period	3	
tDQSS	Write command to first DQS latching transition	1 (0.75 - 1.25 CK)	
tRPRE	Read preamble	1 (0.9 - 1.1 CK)	DQS is held low for read when driving on the same cycle as the read command is stopped.

NOTE: The SDRC uses tXSR only when exiting self-refresh mode, regardless of the first command issued. The SDRC systematically inserts an autorefresh command before it serves the first request.

10.2.5.3.4 DLL/CDL Configuration

The DLL unit is configured by writing to the SDRC.[SDRC_DLL_A_CTRL](#) register. This register contains the following fields:

- FIXEDDELAY
- MODEFIXEDDELAYINITLAT
- DLLMODEONIDLEREQ
- DLLIDLE
- ENADLL
- LOCKDLL

To support low-frequency DDR access, set the DLL in fixed delay mode by setting the [SDRC_DLLA_CTRL](#) [2] LOCKDLL bit to 0x1. In this mode, the [SDRC_DLLA_CTRL](#) [31:24] FIXEDDELAY field allows the programming of the CDL delay. This provides the correct fixed DCB code based on the input frequency. Only the voltage precharge part of the DLL is still used to control the CDL instances in this mode, but the control loop is broken and the voltage control is inactive.

When fixed delay mode is enabled, a counter (programmable through the [SDRC_DLLA_CTRL](#) [23:16] MODEFIXEDDELAYINITLAT field) based on the input frequency allows the SDRC to stall all incoming requests. Once this counter expires, the SDRC starts accessing the memory. The DLL characterization shows that this feature is not useful and that this value shall be set to 0x0, leading actually to a null delay.

The DLL can be put in idle mode using the [SDRC_DLLA_CTRL](#)[4] DLLIDLE bit. When in idle mode, the DLL lock is lost. The precharge voltage is kept stable to enable faster relock when going back to a functional state. If set, this bit overrides the ENADLL bit. Thus, avoid completely powering down the DLL by keeping the precharge voltage and cutting off the analog loop. Exiting from this idle mode saves some clock cycles compared to exiting from power-down mode. Refer to the note (DLL behavior upon a warm reset assertion) in [Section 10.2.4.4.9.2, Dynamic Low-Power Operating Modes](#). Furthermore, the [SDRC_DLLA_CTRL](#)[6:5] DLLMODEONIDLEREQ field defines the modes (power-down/DLLIDLE/No action) of the DLL that are automatically entered upon an Idle_req assertion. The DLL mode (TrackedDelay or ModeFixedDelay mode) is updated only when Idle_req/Idle_ack handshake protocol occurs, warm reset occurs, PWRDN is enabled, or DLLIDLE mode enabled. Power-down mode is asserted upon warm reset assertion. If power-down and DLLIDLE are asserted simultaneously, power-down overwrites DLLIDLE mode inside the DLLCDL cell.

To modify the SDRC input clock when the DLL is locked and active, the DLL must first enter either its idle mode or its power-down mode. The SDRC input frequency can be changed by using any of the following scenarios:

- Internal signals handshaking protocol with PRCM module
- Warm reset event
- DLLIDLE mode
- Power-down mode

The ENADLL bit controls the PWRDN mode of the DLL module.

The LOCKDLL bit sets the DLL in TrackedDelay (lock) or ModeFixedDelay (unlock) mode. ModeFixedDelay mode is supported up to 83 MHz.

See [Section 10.2.4.4.11](#) for more information on the CDL/DLL module.

DLLMODEONIDLEREQ is of no importance to the Idle_ack generation. In case DLLMODEONIDLEREQ = 2 and Idle_req occurs, Idle_ack can be generated and SDRC/core can go to idle; however, recovery from this state may be incorrectly performed and the DLL cannot relock. If this happens, the only solution to recover is to disable and then re-enable the DLL. DLLMODEONIDLEREQ = 2 is not a valid configuration under Idle_req assertion and must not be used. DLLMODEONIDLEREQ can be set 0 or 1, depending on whether the priority is shorter wake-up latency or lower power consumption.

10.2.5.3.5 Mode Register Programming and Modes of Operation

The SDRC contains a group of registers known as the memory mode registers. These registers define the operational modes of the target SDRAM.

- MR: Mode register used to define operational parameters common to SDR and DDR SDRAMs.
- EMR1: Extended mode used to define operational parameters exclusive to DDR SDRAM (irrelevant to the SDRC since regular DDRs are not supported).
- EMR2: Extended mode used to define operational parameters exclusive to mobile SDRAM.

10.2.5.3.5.1 Mode Register (MR)

The 12-bit SDRC.[SDRC_MR_p](#) register ($p = 0$ or 1 for CS0 or CS1) is common to all SDR and DDR SDRAMs and controls the following parameters:

- Write burst mode

- CAS latency
- Serial/interleaved mode
- Burst length

When programming the SDRC.[SDRC_MR_p](#) bit fields (where p = 0 or 1 for SDRC CS0 or CS1), consider the following:

- CAS latencies of 1, 2, 3, 4, and 5 are supported (CASL).
- Only serial mode (not interleaved mode) is supported (SIL = 0x0).
- A burst length of 2 is supported for SDR SDRAM (BL = 0x2).
- A burst length of 4 is supported for DDR SDRAM (BL = 0x4).
- Burst lengths of 1 (BL = 0x0), 8 (BL = 0x3), and full page (BL = 0x7) are not supported.

Writing to SDRC.[SDRC_MR_p](#) initiates an implicit Load Mode register command qualified by BA1,BA0 = 0,0 except if the NOMEMORYMRS bit is set.

10.2.5.3.5.2 Extended Mode Register 2 (EMR2)

The SDRC.[SDRC_EMR2_p](#) register (p = 0 or 1 for CS0 or CS1) is specific to mobile SDRAM devices. It is a 12-bit register that controls the following standard parameters:

- Partial Array Self-Refresh (PASR)
- Temperature Compensated Self-Refresh (TCSR)
- Driver Strength (DS)

The SDRC.[SDRC_EMR2_p](#)[2:0] PASR field programs the partial array self-refresh feature. The low power SDR SDRAM granularity is much finer than the granularity available in a mobile DDR SDRAM. The SDRC.[SDRC_EMR2_p](#)[4:3] TCSR field programs the temperature compensated self-refresh feature. The TCSR granularity available in a low power SDR is much finer than the granularity available in a mobile DDR.

Writing to SDRC.[SDRC_EMR2_p](#) initiates an implicit load mode register command qualified by BA1, BA0 = 1,0 except if [SDRC_SYS CONFIG](#)[8] NOMEMORYMRS is set.

10.2.5.3.6 Autorefresh Management

The SDRAM refresh configuration register group controls refresh management in normal operation. This group contains two SDRC.[SDRC_RFR_CTRL_p](#) registers that are defined on a per-CS basis and contain the following bit fields:

- SDRC.[SDRC_RFR_CTRL_p](#)[1:0] ARE (where p = SDRC CS value 0 or 1)
- SDRC.[SDRC_RFR_CTRL_p](#)[23:8] ARCV (where p = SDRC CS value 0 or 1)

These bit fields can enable and disable autorefresh. Autorefresh bursts of 1, 4, and 8 are programmed using these fields. The autorefresh burst starts when the 16-bit autorefresh counter decrements to 0. The ARCV field loads the autorefresh counter with a 16-bit autorefresh value. The ARCV value is calculated using the following formula:

$$\text{Refresh value} = (\text{refresh interval} / \text{clock period} / \text{number of rows}) - \text{margin}$$

Note: Memory refresh interval in time unit. Margin is 50 (cycles).

The margin considers the possibility of an ongoing access when the counter expires, thus delaying the effective refresh sequence.

The value to be programmed is independent of the burst-refresh configuration: if a burst-refresh is configured, the value is automatically scaled in hardware to the burst-refresh size.

Autorefresh is enabled by programming the SDRC.[SDRC_MANUAL_p](#)[3:0] CMDCODE field to 0x2 (where p = 0 or 1 for SDRC CS0 or CS1).

10.2.5.3.7 Page Closure Strategy

The page closure strategy is defined on a per-bank basis by setting the SDRC.[SDRC_POWER_REG\[0\]](#)PAGEPOLICY bit. SDRC defines one type of page closure strategy:

1. High power/high bandwidth: Bandwidth consumption is critical.

The SDRC tracks open pages. The SDRC determines whether the current access is an open page or a closed page. The SDRC does the following:

1. If the current page is already open on this bank the SDRC automatically issues a *precharge* command to close that bank.
2. Opens the accessed page
3. Executes the access

In the worst case, four pages (one page per bank) may be opened simultaneously.

The PAGEPOLICY bit must be set to 1 to enable this mode.

10.2.5.4 Manual Software Commands

The manual commands register SDRC.[SDRC_MANUAL_p](#) (where p = 0 or 1 for SDRC CS0 or CS1) is used to implement software-driven commands:

- NOP command
- Precharge All command
- Autorefresh command
- Enter deep-power-down command
- Exit deep-power-down command
- Enter self-refresh command
- Exit self-refresh command
- Set CKE high command
- Set CKE low command

These commands are described in the following section:

- NOP (CMDCODE: 0x0)

When the SDRC.[SDRC_MANUAL_p\[3:0\]](#) CMDCODE field is programmed with 0x0, the SDRC issues a NOP/inhibit command. The following table lists the status of the SDRC memory port signals.

NOP does not initiate any new operation, but it is needed to complete operations that require more than a single clock cycle-like autorefresh.

Inhibit is also a NOP. nCS high disables the command decoder so that nRAS, nCAS, nWE, and all the address inputs are ignored.

Command	nCS	nRAS	nCAS	nWE
Inhibit	H	X	X	X
NOP	0	H	H	H

- Precharge all (CMDCODE: 0x1)

When the SDRC.[SDRC_MANUAL_p\[3:0\]](#) CMDCODE field is programmed with 0x1, the SDRC issues a precharge all command. The following table lists the status of the SDRC memory port signals.

During the command, address A10 remains high, and bank information (BA0 and BA1) is don't care.

All banks can be precharged at the same time by using the precharge all command.

At the end of tRP, after performing precharge on all of the banks, they enter the idle state.

Command	A10	nCS	nRAS	nCAS	nWE
Precharge all	H	L	L	H	L

- Autorefresh (CMDCODE: 0x2)

When the SDRC.[SDRC_MANUAL_p\[3:0\]](#) CMDCODE field is programmed with 0x2, the SDRC issues an autorefresh command. The following table lists the status of the SDRC memory port signals.

In addition to the signal status mentioned below, the CKE signal is at logic high for autorefresh.

The autorefresh command can only be asserted when all banks are in idle state and the device is not in power-down mode (CKE is high in the previous cycle).

The autorefresh command must be followed by NOPs until the autorefresh operation completes.

All banks are in the idle state at the end of the autorefresh operation.

Command	nCS	nRAS	nCAS	nWE
Autorefresh	L	L	L	H

- Enter deep-power-down (CMDCODE: 0x3)

When the SDRC.[SDRC_MANUAL_p\[3:0\]](#) CMDCODE field is programmed with 0x3, the SDRC executes an enter DPDM command. This command is used for low-power devices (that is, LPSDR or MDDR devices that support deep-power-down mode). The following table shows the status of the SDRC memory port signals.

The device enters deep-power-down mode by having nCS and nWE held at logic low with nRAS and nCAS high at the rising edge of the clock, while CKE is low.

Command	nCS	nRAS	nCAS	nWE	CKE
Enter DPDM	L	H	H	L	L

- Exit deep-power-down command (CMDCODE: 0x4)

When the SDRC.[SDRC_MANUAL_p\[3:0\]](#) CMDCODE field is programmed with 0x4, the SDRC executes an exit deep-power-down command. The device exits deep-power-down mode when the inhibit command is sampled with CKE held at logic high.

- Enter self-refresh (CMDCODE: 0x5)

When the SDRC.[SDRC_MANUAL_p\[3:0\]](#) CMDCODE field is programmed with 0x5, the SDRC puts the memory into self-refresh. The signal status is the same as defined in autorefresh, and CKE is held at logic low during the self-refresh entry command.

The self-refresh mode is entered from the all-banks-idle state by asserting nCS, nRAS, nCAS, and CKE low, and nWE high.

Once the self-refresh mode is entered, only the CKE state being low matters; all other inputs, including the clock, are ignored and remain in self-refresh mode.

- Exit self-refresh (CMDCODE: 0x6)

When the SDRC.[SDRC_MANUAL_p\[3:0\]](#) CMDCODE field is programmed with 0x6, the SDRC executes the self-refresh exit command and, after meeting the tXSR timing parameter, executes one autorefresh command to adhere to the memory protocol. It is an exit self-refresh command when CKE is detected high with a NOP command.

Self-refresh is exited by restarting the external clock and then asserting CKE high. This must be followed by NOPs for a minimum time of tXSR before the SDRAM reaches idle state to begin normal operation.

- Set the CKE signal high (CMDCODE: 0x7)

When the SDRC.[SDRC_MANUAL_p\[3:0\]](#) CMDCODE field is programmed with 0x7, CKE is set to high. An example of where this command is used is during DDR memory initialization.

- Set the CKE signal low (CMDCODE: 0x8)

When the SDRC.[SDRC_MANUAL_p\[3:0\]](#) CMDCODE field is programmed with 0x8, CKE is set to low. An example of where this command can be used is to put memory in power-down mode.

10.2.5.4.1 Low-Power SDR/Mobile DDR Initialization Sequence

The initialization sequence is executed after the following occur:

1. Power is applied.
2. The clock is stable.
3. The power-on reset sequence is executed.

The initialization sequence is executed by programming the following manual command registers, in the SDRC.[SDRC_MANUAL_p\[3:0\]](#) CMDCODE bit field, on a per-CS basis:

1. Set CMDCODE to 0x0 (NOP command), for a minimum delay of 200 μ s. Another way to stabilize the connected device internal circuits is to deactivate the corresponding CS for the same amount of time.

CAUTION

Programmers must ensure that the next command (precharge-all command) is sent after a minimum delay of 200 μ s. Other timings, such as tRP timing between the precharge-all command and autorefresh command, are handled automatically by the SDRC depending on the timing values programmed in the appropriate registers.

2. Set CMDCODE to 0x1 (precharge all command) to precharge all banks.
3. Set CMDCODE to 0x2 (autorefresh command). The autorefresh command is automatically generated after a time of tRP, hence [SDRC_ACTIM_CTRLA_p\[17:15\]](#) TRP (where p = 0 or 1, for CS0 or CS1) must be programmed as stated in the external memory datasheet.
4. A second autorefresh command must be programmed. Set CMDCODE to 0x2 another time.
5. Then configure the mode register [SDRC_MR_p](#) (p = 0 or 1) with BA0 and BA1 set to 0.

Because the mode register powers up in an unknown state, it must be loaded before applying any operational command.

When MR is reprogrammed, a suitable time must elapse before an active command is issued. The hardware ensures this by fixing tMRD to two clock cycles. The SDRC can handle CKE as force on CKE is released through the control module.

After VDD initialization sdrc_cke0 and sdrc_cke1 signals are forced outside the SDRC subsystem by the control module. When the external SDRAM device is correctly initialized the control module must release the force on these sdrc_cke signals by clearing the corresponding MUXMODE bit fields in CONTROL.CONTROL_PADCONF_SAD2D_SBUSFLAG[18:16] and CONTROL.CONTROL_PADCONF_SDRC_CKE1[2:0] bit fields for sdrc_cke0 and sdrc_cke1 respectively. See [Section 10.2.5.2.2](#) for more information on reset behavior.

10.2.5.4.2 Read/Write Access

The commands required for a normal read/write access are automatically generated as a function of the following:

- The read/write command
- The address bus. A10 defines precharge all
- The relevant [SDRC_MR_p](#) / [SDRC_EMR2_p](#) registers

10.2.5.4.3 Memory Power Management

10.2.5.4.3.1 Clock Enable Management

The SDRC supports two autonomous clock enable pins CKE0 and CKE1. Each CS (CS0 or CS1) has its own CKE signal. Power management of the CS0 memory is controlled by CKE0. Power management of the CS1 memory is controlled by CKE1. This allows the SDRAM memories associated with CS0 or CS1 to be independently placed in power-down, deep-power-down (DPD) or self-refresh (SR) mode. This is achieved using the manual control register SDRC.[SDRC_MANUAL_p\[3:0\]](#) CMDCODE field which is defined on a per chip select basis. Entry and exit of these low-power modes is achieved using the relevant CMDCODE.

Once the memory associated with a CS has been powered down in deep-power-down mode it cannot be powered up by dynamic power management features. It can only exit the low-power state through the programming of the relevant CMDCODE. The SDRC can automatically exit other low-power modes.

10.2.5.4.3.2 Clock-Controlled Memory Power Management

The SDRC power-management register (SDRC.[SDRC_POWER_REG](#)) contains the EXTCLKDIS field, which controls suspension of the external clock on a per-CS basis. Writing 1 to this field in the relevant register freezes the clock with a latency dependent on the SDRC.[SDRC_POWER_REG](#) register programming. Subsequently, writing 0 to this field in the relevant register enables the clock with a latency dependent on the SDRC.[SDRC_POWER_REG](#) register programming.

10.2.5.4.3.3 Manual Power-Down Mode Power Management

For dynamic power-down mode refer to [Section 10.2.4.4.9.2, Power-Saving Features](#). The programming model for manual power-down mode is different for an SDR and a DDR.

SDR Mechanism/Power-Down Mode Entry

1. Ensure that no accesses are pending or active.
2. Program the CMDCODE field of the relevant manual command register to 0001.
This ensures that all banks are idle by executing a precharge all command.
3. Wait two clock cycles.
4. Program the CMDCODE field of the relevant manual command register to 0000.
This executes a NOP command.
5. Program the CMDCODE field of the relevant manual command register to 1000.
This sets CKE low.
6. Maintain the clock at a stable value.

SDR Mechanism/Power-Down Mode Exit

1. Provide clock.
2. Program the CMDCODE field of the relevant manual command register to 0111.
This sets the relevant CKE high.
3. Program the CMDCODE field of the relevant manual command register to 0000.
This executes a NOP command.
4. Program the CMDCODE field of the relevant manual command register to 0001.
This ensures that all banks are idle by executing a precharge.

The length of time the SDRC spends in power-down mode must not exceed the refresh period; otherwise, data becomes corrupted.

For a DDR, the sequence is as follows:

DDR Mechanism/Power-Down Mode Entry

1. Ensure that no access is currently pending or active.
2. To reduce power consumption (not mandatory): disable DLL by setting the ENADLL field of the relevant SDRC.[SDRC_DLLA_CTRL](#) register to 0x0.
3. Program the CMDCODE field of the relevant manual command register to 0001.
This ensures that all banks are idle by executing a precharge all command.
4. Program the CMDCODE field of the relevant manual command register to 0000.
This executes a NOP command.
5. Program the CMDCODE field of the relevant manual command register to 1000.
This sets the relevant CKE low.
6. Maintain the clock at a stable value.

DDR Mechanism/Power-Down Mode Exit

1. Provide clock.
 2. Program the CMDCODE field of the relevant manual command register to 0111.
This sets the relevant CKE high.
 3. Program the CMDCODE field of the relevant manual command register to 0000.
This executes a NOP command.
 4. Program the CMDCODE field of the relevant manual command register to 0001.
This ensures that all banks are idle by executing a precharge all command.
 5. Enable DLL by setting the ENADLL field of the relevant SDRC.[SDRC_DLLA_CTRL](#) register to 0x1.
- The amount of time the SDRC spends in power-down mode must not exceed the refresh period; otherwise, data becomes corrupted.

10.2.5.4.3.4 Deep-Power-Down Mode Power Management

When in deep-power-down mode the power distribution to the entire memory array is cut. The programming model for deep-power-down mode is as follows:

Deep-power-down Mode Entry

- Precharge all banks (CMDCODE: 0x1). This ensures that all banks are idle.
- Enter deep-power-down mode (CMDCODE: 0x3).

Deep-power-down Mode Exit

- Exit deep-power-down mode (CMDCODE: 0x4).

The MR and EMR values are retained upon exiting deep-power-down mode.

NOTE: Because power-down entry/exit sequences depend on memory devices, see the memory specification for the complete sequence.

10.2.5.4.3.5 Manual Self-Refresh Mode Power Management

The programming model for entering and exiting self-refresh mode is as follows:

Self-Refresh Entry

- Precharge all banks (CMDCODE: 0x1).
- NOP (CMDCODE: 0x0)
- Enter self-refresh mode (CMDCODE: 0x5).

There is no need for the software to disable the autorefresh in the SDRC.[SDRC_RFR_CTRL_p](#) register before entering self-refresh. The autorefresh counter is reset in hardware so that an autorefresh cycle is automatically generated immediately after a self-refresh exit, and before any other command.

Self-Refresh Exit

- Exit self-refresh mode (CMDCODE: 0x6).
- If needed, reconfigure SDRC registers as required.
- Enable autorefresh by programming:
 - The relevant SDRC.[SDRC_RFR_CTRL_p](#)[23:8] ARCV field
 - The relevant SDRC.[SDRC_RFR_CTRL_p](#)[1:0] ARE field to the desired refresh burst

10.2.5.5 Error Management

All data transfers in the SDRC operate a system of full handshaking. A valid read or write request that is presented to the SDRC by the L3 interconnect sequencer results in the SDRC acknowledging the transfer by raising the SCmdAccept flag. Failure to do this within a defined temporal window constitutes an error. Errors can arise from the following sources:

- Any transaction while the memory is in deep-power-down mode

- An illegal initiator access. The address of the last illegal access is captured in the SDRC.[SDRC_ERR_ADDR](#) register

If an error occurs, the software error handler performs the following actions:

- Interrogates the ERRORVALID field of the SDRC.[SDRC_ERR_TYPE](#) register to verify the presence of an error
- Interrogates the ERRORDPD field of the SDRC.[SDRC_ERR_TYPE](#) register to determine whether a transaction error resulting from the device being in deep-power-down mode is present
- Interrogates the ERRORCONNID field of the SDRC.[SDRC_ERR_TYPE](#) register to determine whether a transaction error resulting from an illegal access by an interconnect initiator is present
- Interrogates the ERRORADD field of the SDRC.[SDRC_ERR_TYPE](#) register to determine whether a transaction error resulting from an illegal address is present:
 - Interconnect access to an address outside the memory space (0x0)
 - Interconnect access to an address outside the register space (0x1)
- Writes 0 to the ERRORVALID field of the SDRC.[SDRC_ERR_TYPE](#) register to clear the active error status
- Executes error recovery from software

10.2.6 SDRC Use Cases and Tips

10.2.6.1 How to Program the VRFB

10.2.6.1.1 VRFB Rotation Mechanism

An inherent limitation of SDRAM technology is high-memory latency caused by page-miss penalties incurred when downloading to a memory cache. For example, switching from one page to another in external memory can cause a page-miss, indicating that the page accessed for the current pixel is different from that for the previous pixel.

A DMA engine is used to rotate pictures in external DRAM, but this rotation method increases the number of page misses.

The efficient way to rotate image data in external SDRAM is to use the VRFB module, which is an RE embedded in the SMS of the device, as shown in [Figure 10-62](#). It is configured in the SMS registers.

Figure 10-62. SDRC Subsystem Overview

sdrc-019

Accessing images stored in external SDRAM in a non-natural order requires an address transaction: the virtual address of an image is translated into a physical address in the corresponding buffer. Address translation causes an image to be rotated in 0-, 90-, 180-, or 270-degree views. With multiple views of the image, the RE can change addresses and issue multiple requests to the SDRC so that a maximum of consecutive accesses is performed, thus decreasing the number of page-miss penalties. The RE cannot reorder requests to the SDRAM.

A VRFB context defines the configuration used to access a picture in external SDRAM. For each VRFB context, a set of registers in the SMS describes:

- The size of the page (height and width)
- The picture parameters before rotation (width, height, and pixel format)
- The rotation angle (0-, 90-, 180-, or 270-degree)
- The physical base address in external memory

Any initiator in the device can access up to 12 images simultaneously, each image having an independent context. These 12 contexts are considered virtually addressed image buffers. Each context is assigned to a physical image buffer.

The virtual address space of each context is subdivided into four separate address regions pointing to the same physical image buffer but corresponding to the four possible rotations: 0/90/180/270.

After the VRFB context is configured, all data accesses to an address space are automatically translated when accessing SDRAM through the RE.

10.2.6.1.2 Setting a VRFB Context

NOTE: YUV Format

The YUV standard shows a color space with three elements:

- Y for luminance
- U for chrominance
- V for chrominance

As shown in [Figure 10-63](#), pixel format (not pixel size) used in the YUV standard is spread onto a 32-bit data structure:

- This 32-bit data structure represents a packet of two pixels: P0 and P1.
- Each element (Y0, Y1, U, and V) is coded in 8 bits.
- P0 = Y0; U, V, and P1 = Y1, U, V.

There are 24 bits of information per pixel (Y, U, and V); however, because the chrominance elements U and V are common to both P0 and P1 pixels, only 16 bits are used to store a pixel in YUV format. The YUV standard uses a 32-bit data structure to represent 2 pixels; the pixel format uses 32 bits (4 bytes).

Thus, when defining YUV image parameters, the image width must be set to one-half the number of pixels per row and the pixel format must be set to 4 bytes, because the YUV pixel data is spread onto a 32-bit word representing 2 pixels.

[Figure 10-63](#) shows the pixel representation of the YUV format.

Figure 10-63. YUV Format: Pixel Representation

sdrc-020

[Figure 10-64](#) shows a generic way to configure a VRFB context to perform a rotation view on pixel data in external DRAM.

Figure 10-64. VRFB Context Configuration

sdrc-021

Figure 10-65 is an example of VRFB context configuration using both RGB and YUV image formats. This example represents the configuration of a 1024-byte page size (32 * 32 byte page) and a 240 * 240 image size using VRFB context 1.

Figure 10-65. Example of VRFB Context 1 Configuration

sdrc-022

Table 10-107 lists guidelines for calculating image size.

Table 10-107. Calculating Image Size⁽¹⁾ ⁽²⁾

Steps		RGB16 Format (16-Bit Pixel Format)		YUV Format (32-Bit Pixel Format)	
		IMAGEWIDTH	IMAGEHEIGHT	IMAGEWIDTH	IMAGEHEIGHT
1	Calculate the required number of pages per line and per column.	240 pixels/32 bytes * 2 bytes per pixel = 15 pages per line	240/32 rows = 7.5, rounded to 8 pages per column	120 pixels/32 bytes * 4 bytes per pixel format = 15	240/32 rows = 7.5, rounded to 8
2	Using the number of pages calculated in Step 1, calculate the image size in pixels.	15 * 32 bytes/2 bytes per pixel = 240	8 * 32 rows = 256	15 * 32 bytes/4 bytes per pixel format = 120	256

⁽¹⁾ Working on a page basis, the image size must be a multiple of the page size.

⁽²⁾ Depending on the page dimensions and the image size, the programmed image size (256) is larger than the actual image size (240).

To use VRFB rotation, each initiator must configure its DMA engine correctly; an additional offset to the base address may be required. For details, see [Chapter 7, Display Subsystem](#).

10.2.6.1.3 Applicative Use Case and Tips

Use Case Scenario: Display a Rotated QVGA Image

[Figure 10-66](#) shows the use case for displaying a rotated QVGA image. The camera captures an image with a particular rotation and stores the pixel data in external memory. Displaying the image on the DSS requires a different orientation.

Figure 10-66. Display a Rotated QVGA Image

sdrc-023

The following components interact while displaying the rotated image:

- SDRC subsystem
- Camera subsystem
- Display subsystem
- External DDR
- VRFB

The following conditions exist for this application:

- QVGA image size is 320 * 240 (width * height).
- Pixel format is YUV4:2:2 (YUV2) in little endian.
- The rotation view is 90 degrees.
- The VRFB context is VRFB context 1.
- The camera module writes QVGA images to external DRAM at 15 fps.
- The display subsystem reads QVGA images from external DDR32 at 60 fps and displays them on the LCD screen.

- Read and write initiators use burst mode:
 - The camera uses 8 * 64-bit burst size.
 - The display uses 8 * 32-bit burst size.
 - Double-indexing mode is selected.
- The physical address of the buffer in external memory is 0x8030 0000.
- The memory allocation for the buffer is 320 * 240- * 16-bit (or 160 * 240 * 32-bit).
- The camera subsystem uses its dedicated DMA channel 0.
- The display subsystem uses its video channel 1.

Configuring the VRFB Through the SMS Registers

The size of the page supported by the DDR32 memory is 1K byte, which is arranged as 32 * 32 bytes page (width * height).

Configuring the page size:

- [SMS_ROT_CONTROLn\[6:4\]](#) PW = 5 (where n = 1)
- [SMS_ROT_CONTROLn\[10:8\]](#) PH = 5

Configuring the image parameters:

- [SMS_ROT_SIZEn\[10:0\]](#) IMAGEWIDTH = 160 (where n = 1)
- [SMS_ROT_SIZEn\[26:16\]](#) IMAGEHEIGHT = 256
- [SMS_ROT_CONTROLn\[1:0\]](#) PS = 2

Physical base address and rotation angle:

- [SMS_ROT_PHYSICAL_BAn\[30:0\]](#) PHYSICALBA = 0x8030 0000 (where n = 1).

The image data is accessed at the following virtual address range for 90-degree rotation: 0x7500 0000 - 0x75FF FFFF.

CAUTION

Image rotation using the YUV2 image format causes the stream to become untidy. The display must be specifically configured to read and reorganize the stream to conform to the YUV2 standard.

Tips for Configuring Successful Rotation

The following guidelines ensure optimal image rotation:

- Page arrangement:

Usually, the recommendation is to have a *square* page. If this is not possible, the longest page side should correspond to the access direction that requires the maximum bandwidth; set the longest page side to optimize the page break.

Using a 1024-byte page size, a 32 * 32-byte page arrangement is used as an example. With a 2K-byte page organized as a 32 * 64 byte page, depending on the read or write operation, set the longest page size to optimize the page break. If 0 is written and the 270-degree view is read, page height is greater than page width (PH > PW). Set PH to 64 bytes (PH = 6).
- Virtual address memory arrangement:

When accessing image data through virtual addresses, the maximum line size supported by the VRFB is 2,048 pixels.

In the memory buffer, the distance between two vertically adjacent pixels is fixed at 2,048 multiplied by the pixel format in bytes. This means that when reading or writing image data through virtual addresses, there must be an offset of: (2048 - IMAGEWIDTH) * PS bytes at the end of every line.
- Base address alignment:

For optimization, the base address is aligned on the page size. For instance, a 1K-byte page size organized as a 32 * 32-byte page is aligned on 0x400 (to be adjusted on the base address).

- To improve performance on 90° rotation consider two things:
 - Because a read access can appear more critical than a write access, a posted write may be appropriate.
 - When performing burst accesses with 90° or 270° rotation views, the burst is split on the memory side, adding latency.
- For a burst access with 90° rotation, split the data of the burst on the write side (not the read side):
- Write in 270° and read in 0°.

10.2.6.2 SMS Mode of Operation

10.2.6.2.1 SDRAM Memory Scheduler and Arbitration Policy

The SDRAM memory scheduler improves access to external memory by:

- Optimizing SDRAM bandwidth
- Prioritizing requests to external memory

This mechanism relies on a complex arbitration policy that employs specific terminology:

- Group: a FIFO queue of requests from initiators
- Class: A collection of groups
- Transaction: A full burst request
- Arbitration grant: Authorization of a service requested by an initiator

The arbitration policy operates on two interdependent mechanisms:

- The arbitration decision, which establishes priority for processing requests. The question: Which request is processed next? occurs on a transaction boundary.
- Arbitration granularity, which determines the length of an arbitration grant. The question: How long to keep the grant? defines the boundary of the arbitration decision point in time.

Figure 10-67 shows the link between these two concepts. On a transaction boundary, the questions: What request is serviced next, and for how long? merge the two mechanisms. The mechanisms for specifying the granularity of requests also influence the boundary of a transaction.

Figure 10-67. Arbitration Granularity Versus Arbitration Decision

Duration of a transaction:
 How long to track the transaction?
 (it depends on the granularity settings)

Arbitration decision on a transaction boundary:
 Which group has the priority?

sdrc-024

10.2.6.2.2 Arbitration Decision

The SMS module controls arbitration. Requests from initiators for access to the external SDRAM are collected into several independent FIFO queues, and each queue is assigned to a class. Priority is then assigned to groups and classes; this defines the next request to be serviced.

10.2.6.2.2.1 Burst-Complete Mechanism

The burst-complete mechanism applies granularity to the arbitration scheme. Access cannot be granted to a group within a class until a complete burst has been stored in the FIFO.

Example:

There is no ongoing transaction on Class 0. The initiator requests a $4 * 64$ -bit burst on Group 3 of Class 2 ([SMS_CLASS_ARBITER\[27\]](#) BURST-COMPLETE = 0x1). Only $2 * 64$ -bit requests are stored in the FIFO.

The mode of operation is:

- Wait for the last $2 * 64$ -bit request to be stored in the FIFO.
- Arbitration is requested once all requests of a burst have been received.
- After the $4 * 64$ -bit burst is complete, the transaction occurs.
- The arbitration choice mechanism resumes:
 - Were there any incoming requests during the last transaction?
 - What is the next request to be serviced/granted?

Figure 10-68. BURST-COMPLETE On Class 2-Group 3

sdrc-025

10.2.6.2.2.2 Priority Between Groups

The SMS.SMS_CLASS_ARBITER[7:6] HIGHPRIOVECTOR field defines the priority between groups in a class.

10.2.6.2.2.3 Priority Between Classes

Class 0 always has the highest priority. Then, a weight is programmed within the arbitration of Class 1 and Class 2:

- The SMS.SMS_INTERCLASS_ARBITER[23:16] CLASS1PRIO field specifies the number (M) of transactions dedicated to Class 1.
- The SMS.SMS_INTERCLASS_ARBITER[7:0] CLASS2PRIO field specifies the number (N) of transactions dedicated to Class 2.

M and N parameters are used to set a PWM arbitration. For instance, two schemes appear: at time t, Class 1 is serviced for M cycles, and is directly followed by service to Class 2 for N cycles. If Class 2 is serviced first for N cycles, then Class 1 is granted for M cycles. Arbitration is given more importance; Class 1/2 is favored over Class 2/1. As shown in [Figure 10-69](#), two arbitration schemes can appear:

- Class 0 is serviced first, followed by Class 1, and then Class 2 (C0 - C1 - C2).
- Class 0 is serviced first, followed by Class 2, and then Class 1 (C0 - C2 - C1).

Figure 10-69. Priority Between Classes

SMS_INTERCLASS_ARBITER[7:0] CLASS1PRIO field:
defines the number \bar{M} of transactions dedicated to class 1.

SMS_INTERCLASS_ARBITER[23:16] CLASS2PRIO field:
defines the number N of transactions dedicated to class 2.

sdrc-026

10.2.6.2.3 Arbitration Granularity

Arbitration is the mechanism that give more or less importance to incoming requests depending on the initiator origin. Granularity influences the boundary of a transaction because it imposes the following questions:

- How many requests to service?
- How long to track the current transaction?
- When to make the next arbitration decision, or when does the next transaction boundary occur?

10.2.6.2.3.1 Idle Cycle

The idle gives more granularity to the arbitration; it lets the arbiter wait one idle cycle before moving the arbitration grant to another thread.

Within a burst (see [Figure 10-70](#) for an example):

1. A thread requests a burst transaction. According to the thread ID, the last request was serviced on Class 2 - Group 2.
2. The thread cannot provide the subsequent request of the burst. The module waits for one idle cycle without moving the arbitration grant, to receive the subsequent request (from the same thread).
3. On the second idle cycle, if the subsequent request has not been received, the arbitration grant is moved so that a request from another thread is serviced.

Figure 10-70. Idle Cycle Mechanism Within A Burst

sdrc-027

Two bursts must be serviced at the burst boundary. One idle cycle after servicing these two bursts, the arbitration grant is moved.

10.2.6.2.3.2 Extended-Grant Mechanism

The extended-grant mechanism gives additional granularity to the arbitration. An extended grant defines the number of consecutive transactions (from 1 to 3) a group is granted.

Example:

Requests were already available on Class 1-Group 0 and Class 2-Group 3.

An arbitration decision occurs: grant access to Class 1-Group 0.

A request is now being serviced on Class 1-Group 0 with `SMS_CLASS_ARBTER1[9:8]`

EXTENDEDGRANT = 0x3 (three consecutive transactions are granted to Group 0). The mode of operation is:

- Process the request for three cycles.
- If another request comes from another class (even Class 0) during the processing, it is ignored; the arbiter does not treat incoming requests.
- After three consecutive transactions, return to the arbitration decision:
 - Were there any incoming requests during the last transaction?
 - What is the next request to be serviced?

[Figure 10-71](#) shows this mechanism on Class 1-Group 0:

Figure 10-71. Example of EXTENDEDGRANT Mechanism

sdrc-028

10.2.6.2.3.3 Number of Service Mechanism.

The [SMS_CLASS_ROTATIONm\[4:0\]](#) NOFSERVICES field defines the number of consecutive transactions (from 1 to 31) the VRFB is granted. For more information on LRU policy and Number of Service, refer to [Section 10.2.4.1.3](#).

10.2.6.2.4 How these Mechanisms Interact

As described in the previous sections, the arbitration within the SMS module is based on several mechanisms giving even more importance to the arbitration. When we need to grant the access on a transaction boundary, we recall that the question we have to answer is: What will be the next request to be serviced, and for how long?

Thus, the two important concepts regarding the SMS mode of operation are:

- The arbitration decision: we choose the next request to be serviced and so we grant it the access to the external memory.
- The arbitration granularity: depending on the mechanism used, we define the boundary of the transaction: how long do we keep the grant?

[Figure 10-72](#) describes the decision happening between classes.

[Figure 10-73](#) explains the priority between groups within Class 1.

So far, the arbitration decision has taken place at class boundaries and within a class containing two groups. [Figure 10-74](#) recalls the generic way to service and therefore prioritize the requests within a class. Finally, [Figure 10-75](#) recalls mechanisms used to define the boundary of the transaction being serviced (how long do we keep the grant?).

sdrc-032

10.2.6.3 Understanding SDRAM Subsystem Address Spaces

One thing that the SMS does is to translate virtual addresses into physical SDRAM addresses in case of rotation only; that is, when accessing virtual address space 0 (quarter 1) and virtual address space 1 (quarter 3) as shown in [Figure 10-76](#). The SMS then reinserts a request, or multiple requests depending on the SMS parameters, in the SMS request path to the SDRC (through the VRFB or not).

The SDRAM subsystem global memory space mapping reaches 1.768G-bytes:

- 1G-byte of CS memory space (CS0 and CS1 memory spaces): the SDRC automatically accesses the two external memory devices through direct accesses (addresses are simply translated).
- 768M-bytes of virtual address space (address space 0 and address space 1): the SDRC automatically accesses the two external memory devices through re-organized access (requests are modified accordingly to the context number and rotation angle before address translation). See section [Section 10.2.6.3.1.2](#) for more information on VRFB contexts and rotation angles.

Figure 10-76. SDRC Address Space in MPU Global Address Space

Configuration register space is detailed in [Table 10-108](#).

Table 10-108. SDRC and SMS Configuration Register Space

Module	Start Address	End Address	Total Space
SMS	0x6C00 0000	0x6CFF FFFF	16 MB
SDRC	0x6D00 0000	0x6DFF FFFF	16 MB

10.2.6.3.1.1 Physical Address Space

The physical address space of the SDRC is 1G byte (maximum addressing capability).

The SDRC has a memory device capacity of 16M bits to 2G bits. The smallest granularity of supported memory device is 16M bits/2M bytes.

10.2.6.3.1.2 Virtual Address Space

The SDRC-SMS virtual memory space is a memory space used to access a subset of the SDRC memory space through the rotation engine (VRFB). The virtual address space size is 768M bytes split into two parts: the first 256M-byte part is in the second quarter (Q1) of the memory; the second 512M-byte part is in the fourth quarter (Q3) of the memory. See [Chapter 2, Memory Mapping](#), for more information on global memory mapping.

The VRFB is a rotation engine that:

- Supports rotations of 0, 90, 180, and 270 degrees
- Can handle up to 12 concurrent rotation contexts

The VRFB has therefore 48 different contexts in the virtual address space. [Table 10-109](#) gives the VRFB address-space memory locations at which the frame buffer object can be accessed. The table summarizes the virtual addresses of all 48 available image buffer from a global memory space (top level) point of view.

Table 10-109. VRFB Contexts vs Rotation Angle

Context Number	0°	90°	180°	270°
0	0x7000 0000	0x7100 0000	0x7200 0000	0x7300 0000
1	0x7400 0000	0x7500 0000	0x7600 0000	0x7700 0000
2	0x7800 0000	0x7900 0000	0x7A00 0000	0x7B00 0000
3	0x7C00 0000	0x7D00 0000	0x7E00 0000	0x7F00 0000
4	0xE000 0000	0xE100 0000	0xE200 0000	0xE300 0000
5	0xE400 0000	0xE500 0000	0xE600 0000	0xE700 0000
6	0xE800 0000	0xE900 0000	0xEA00 0000	0xEB00 0000
7	0xEC00 0000	0xED00 0000	0xEE00 0000	0xEF00 0000
8	0xF000 0000	0xF100 0000	0xF200 0000	0xF300 0000
9	0xF400 0000	0xF500 0000	0xF600 0000	0xF700 0000
10	0xF800 0000	0xF900 0000	0xFA00 0000	0xFB00 0000
11	0xFC00 0000	0xFD00 0000	0xFE00 0000	0xFF00 0000

The physical address of a page is calculated with the formula:

$$\text{Physical address} = \text{Physical base address} + \text{Base address of page} \quad (31)$$

where *Physical base address* is defined through the [SMS_ROT_PHYSICAL_BAn\[30:0\]](#) PHYSICALBA field (buffer physical base address on which the rotation occurs), and *Base address of page* is the address obtained in the function of the context number and rotation angle, as given in [Table 10-109](#).

10.2.6.3.2 CS Memory Spaces

Two SDRC chip-selects (sdrc_ncs0 and sdrc_ncs1) are available to access two external SDRAM memories.

10.2.6.3.2.1 SDRAM Capacity Calculation

This section aims to explain how to calculate an SDRAM device capacity.

From the following SDRAM characteristics:

- Four banks: BA0 - BA1
- Row addresses: A0 - A12
- Column addresses: A0 - A9
- 16-bit data bus to external memory

First calculate the number of addressable locations:

- Number of address lines: 13 (A0-A12)
- Number of banks address lines: 2 (BA0-BA1)

- Maximum number of rows = 13 (number of address lines used for row decoding)
 - Maximum number of columns = 10 (number of address lines used for column decoding)
- Total locations in a bank = $(2^{13}) * (2^{10})$ (32)

Then calculate the total locations in the device:

$$\text{Total locations in the device} = (\text{Number of banks}) * (\text{Total locations in a bank}) = (2^2) * (2^{13} * 2^{10}) = 2^{25} \quad (33)$$

Finally calculate the SDRAM device capacity:

$$\text{Total device capacity} = (\text{Total locations in the device}) * (\text{Device organization}) = (2^{25}) * (16) = 2^{29} \text{ bits} \quad (34)$$

Hence, the device has a maximal capacity of 512M bits (or 64M bytes).

In the same way, the SDRC maximal capacity can be calculated as follow:

- Number of address lines: 15 (A0-A14)
- Maximum number of rows = 15 (limited by the number of address lines, hence do not program **SDRC_MCFG_p[26:24]** RASWIDTH above 15)
- Maximum number of columns = 12 (limited by **SDRC_MCFG_p[22:20]** CASWIDTH)
- Data bus width to external device: 32-bit

$$\text{SDRC total capacity} = (2^{15} * 2^{12}) * 32 = 4\text{G bits (or 512M bytes)} \quad (35)$$

Hence, the SDRC has a maximum addressing capability of 8G bits/1G byte (as seen in [Section 10.2.6.3.1.1](#)) and can manage SDRAM devices with capacity of up to 4G bits/512M bytes.

10.2.6.3.2.2 CS Size

Each chip-select has its programmable size. The CS size is expressed in **SDRC_MCFG_p[17:8]** RAMSIZE (p = 0 or 1 for CS0 or CS1) as a number of 2M-byte chunks.

For instance, when connecting a 256M-bit SDRAM memory (see the mux scheme MUX7 in [Table 10-96](#)) to the SDRC, RAMSIZE must be set with the value 0x010 (32M bytes = 2MB * 16).

10.2.6.3.2.3 CS Start and End Addresses

See [Figure 10-77](#), CS0/CS1 Chip-Select Start Address Slots, for a graphical representation of CS starts addresses and CS size.

CS0 start address is fixed at :

- 0x0000 0000 from an SDRC point of view
- 0x8000 0000 from a global memory space point of view.

Therefore, when connecting a 256M bit/32M-byte SDRAM memory (16M * 8 such as in MUX6, [Table 10-96](#)), the CS0 end address is 0x0200 0000 (SDRC point of view).

CS1 start address is programmable and its default value is :

- 0x2000 0000 from an SDRC address point of view
- 0xA000 0000 from a global memory space point of view.

The SDRC 1G-byte address space is segmented into eight 128M-byte address spaces, which are themselves segmented into four 32M-byte address spaces so that 32 possible CS1 start address locations are defined, as shown in [Figure 10-77](#). The first 32M-byte address space of the first 128M-byte address space is reserved for CS0 (address 0x0000 0000). Any other address can be used as the CS1 start address. To define a CS1 start address, set the **SDRC_CS_CFG[9:8]** CS1STARTLOW and **SDRC_CS_CFG[3:0]** CS1STARTHIGH fields as follows:

- **SDRC_CS_CFG[3:0]** CS1STARTHIGH corresponds to one of the eight 128M-byte address spaces (total address space of SDRC is 1G-byte): 0x0000 for the first partition up to 0x0111 for the eighth partition. The **SDRC_CS_CFG[3]** must always be set to 0.
- **SDRC_CS_CFG[9:8]** CS1STARTLOW corresponds, for a given 128M-byte address space, to one of the four 32M-byte address spaces: 0x00 for the first, up to 0x11 for the fourth.

Therefore, for a start address of 0x2000 0000 (SDRC point of view) when connecting a 2048-Mbit SDRAM memory (64M * 32 such as in MUX25, [Table 10-97](#)), the [SDRC_CS_CFG\[9:8\]](#) CS1STARTLOW bit field must be set to 0x00 (the first 32M-byte address space, as shown in [Figure 10-77](#)), and the [SDRC_CS_CFG\[3:0\]](#) CS1STARTHIGH bit field must be set to 0x0100 (fourth 128M-byte address space). The start address must be aligned on the memory size.

The CS1 end address (0x3000 0000) can be deduced from the CS1 size (that is, from the RAMSIZE parameter), which takes the value 0x80 when connecting a 2048-Mbit SDRAM memory.

Figure 10-77. CS Start and End Address Configuration Example

sdrc-041

10.2.6.4 How to Choose a Suitable SDRAM

This section describes how to select a suitable SDRAM device to interface with the SDRC. Basically, if an SDRAM device is aligned with the JEDEC LPDDR1 SDRAM standard (JEDEC committee JC42.3), the SDRAM device is likely to be compatible with the SDRC. To ensure that an SDRAM device is fully compatible, see the following sections.

[Section 10.2.6.4.1](#) discusses the SDRAM device features to consider. [Section 10.2.6.4.2](#) discusses the SDRC features to consider. As an example, [Section 10.2.6.4.3](#) lists chosen SDRAM parameters versus the supported characteristics of the SDRC.

10.2.6.4.1 SDRAM Device Parameters

Several settings must be considered when selecting an SDRAM device to interface with the SDRC:

- SDRAM type
- Operating voltage
- Maximum operating frequency
- Maximum memory size
- Memory organization:
 - Number of banks
 - Data bus width
- Burst length
- Page size
- Column address strobe (CAS) latency
- Refresh rate
- AC timing parameters and especially the access time parameter tAC

These parameters are defined in the SDRAM device datasheet and must meet the SDRC specifications.

10.2.6.4.2 SDRC Characteristics

Keeping the SDRAM device settings in mind, the SDRC supports:

- Supported device type: Up to two mobile single data rate (M-SDR) SDRAMs, or up to two low-power double data rate (LPDDR) SDRAMs.
- Maximum supported memory size: 128MB per external SDRAM bank (256- and 512-MB SDRAM may be supported, depending on their implementation)
- Minimum supported memory size: 2MB
- Maximum SDRC addressing capability: 1GB
- Memory organization:
 - Number of internal SDRAM banks: two (for 2-MB and 4-MB memory device only) or four banks (other memory device only)
 - Data path to external SDRAM memory: 16- or 32-bit
- Burst Length: Burst of 2 (M-SDR) and burst of 4 (LPDDR)
- Page size: Programmable value (up to 16K bytes)
- Column address strobe latency (CL): 1 to 5 system clock cycles
- Refresh intervals: Programmable value
- Major operation is 3-3-3 (CL-tRCD-tRP) conditions.
 - CL = 3
 - tRCD = 3 clocks cycle time
 - tRP = 3 clocks cycle time
 - tRRD = 2 clocks cycle time
 - tRAS = 7 clocks cycle time
 - tRC = 10 clocks cycle time

10.2.6.4.3 SDRAM Device Compatibility Verification

In this example, a mobile DDR SDRAM memory with the following characteristics is verified for compatibility:

- Type: Mobile DDR SDRAM
- Size: 512 Mbits (16M * 32 in 4 banks)

Table 10-110 lists the SDRAM versus the SDRC characteristics.

Table 10-110. SDRAM vs SDRC Characteristics

SDRAM Parameter	SDRC	512-Mbit MDDR SDRAM (16M * 32)	Co mpa tibili ty
Device type	Mobile SDR / low-power DDR	Low-power DDR	yes
Operating voltage	VDD = VDDQ = 1.7V to 1.9V; VSS = VSSQ = 0.0V (and LVCMOS 1.8V I/Os)	0.8xVDDQ >= High level <= VDDQ + 0.3V -0.3V <= Low level <= 0.2 * VDDQ 1.8V <= I/O power <= 1.95V	yes
Max operating frequency	200 MHz	200 MHz (DDR400)	yes
Memory size	Min: 16 Mbits, max: 1024M bits (2048 and 4096M bits may be supported)	512 Mbits	yes
Number of banks	2 (16 and 32 Mb) or 4 (other)	4	yes
Data path SDRC/SDRAM	16- and 32-bit	32-bit	yes
Burst length	Burst of 2 (M-SDR) and Burst of 4 (LPDDR)	2, 4, 8	yes
Page size	Up to 16KB	2KB	yes
CAS latency	1 to 5 clock cycles	3	yes
Refresh interval	64 ms / number of rows	7.8 μ s	yes

10.2.7 SMS Register Manual

10.2.7.1 SMS Instance Summary

10.2.7.3 SMS Register Description

This section provides a description of SMS registers.

Table 10-113. SMS_REVISION

Address Offset	0x0000 0000	Instance	SMS
Physical Address	0x6C00 0000		
Description	This register contains the IP revision code. IP revision code is defined at design time		
Type	R		
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
	RESERVED		REV

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0.	R	0x000000
7:0	REV	IP revision code [7:4] Major revision [3:0] Minor revision Examples: 0x10 for 1.0, 0x21 for 2.1	R	See ⁽¹⁾

⁽¹⁾ TI internal data

Table 10-115. SMS_SYSCONFIG

Address Offset	0x0000 0010	Instance	SMS
Physical Address	0x6C00 0010		
Description	This register controls the various parameters of the Interconnect.		
Type	RW		
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
	RESERVED	RESERVED	RESERVED SIDLEMODE RESERVED SOFTRESET AUTODLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Write Os for future compatibility. Read returns 0s.	RW	0x000000
8	RESERVED	Write Os for future compatibility. Read returns 0s.	RW	0x0
7:5	RESERVED	Write Os for future compatibility. Read returns 0s.	RW	0x0
4:3	SIDLEMODE	Power management Req/Ack Control 0x0: Force Idle - An idle request is acknowledged unconditionally 0x1: No Idle - An idle request is never acknowledged. 0x2: Smart Idle - Acknowledgment to an idle request is based on the internal activity of the module 0x3: Reserved - Do not use.	RW	0x0
2	RESERVED	Write Os for future compatibility. Read returns 0.	RW	0x0
1	SOFTRESET	Software reset 0x0: Normal mode (no reset applied) 0x1: Software reset is activated	RW	0x0

SDRAM Controller (SDRC) Subsystem

www.ti.com

Bits	Field Name	Description	Type	Reset
0	AUTOIDLE	Internal interface clock gating strategy 0x0: Interface clock is free-running 0x1: Automatic interface clock gating strategy is applied, based on the interconnect activity	RW	0x1

10.3 On-Chip Memory Subsystem

10.3.1 OCM Subsystem Overview

The on-chip memory subsystem consists of two separate on-chip memory controllers, one connected to an on-chip ROM (OCM_ROM) and the other connected to an on-chip RAM (OCM_RAM). Each memory controller has its own dedicated interface to the L3 interconnect.

Figure 10-78 is an overview of the OCM subsystem.

Figure 10-78. OCM Subsystem Overview

Ocm-003

Multiple L3 initiators (such as remote devices) have access to the RAM through 2D/3D graphics, the MPU subsystem, sDMA, the camera subsystem, the display subsystem, IVA2, and USB.

ROM is used for direct boot code and boot from external NAND flash.

10.3.2 OCM Subsystem Integration

10.3.2.1 Description

The OCM_ROM and OCM_RAM allow transactions between the system initiators and the multiple memories, through the L3 interconnect.

Figure 10-79 shows the integration of the OCM subsystem to the device processor.

Figure 10-79. OCM Subsystem Integration to the Device

10.3.2.2 Clocking, Reset, and Power-Management Scheme

10.3.2.2.1 Clocking

The on-chip boot ROM and RAM are clocked only when they are accessed.

The interface clock OCM_CLK comes from the PRCM module and runs at the L3 interconnect frequency. The OCM_CLK source is PRCM CORE_L3_ICLK output. This clock is also used as the functional clock for the OCM module.

For the OCM subsystem, no register enables the gating of OCM_CLK.

However, OCM does support the handshaking protocol with the PRCM module. It is not programmable by software. The following signals support the handshaking protocol for ROM and RAM devices:

- OCMROM_IDLEREQ/OCMROM_SIDLEACK (for ROM devices)
- OCMRAM_IDLEREQ/OCMRAM_SIDLEACK (for RAM devices)

OCM_CLK is gated if all modules (including the OCM) belonging to the L3 CLK domain send a SidleAck back to the PRCM module after reception of the MidleReq request.

For details, see [Chapter 3, Power, Reset, and Clock Management](#).

When the memory is not accessed by the system, the module performs automatic clock gating. Because the clock to the memory is dynamically gated, there is no extra latency when the clock must be switched on after an idle state.

10.3.2.2.2 Hardware Reset

Global reset of the module is performed by activation of the CORE_RST in the core reset domain (see [Chapter 3, Power, Reset, and Clock Management](#)).

10.3.2.2.3 Power Domain

OCM power is supplied by the CORE power domain (see [Chapter 3, Power, Reset, and Clock Management](#)).

10.3.3 OCM Subsystem Functional Description

10.3.3.1 OCM_ROM

The embedded ROM is used primarily for booting, flashing, and context restoring.

The device-embedded ROM (total 32K bytes) has the following characteristics:

- The OCM_ROM is always accessible, and contains the boot area.
- The OCM_ROM supports single and burst access transactions.
- The OCM_ROM operates at full interconnect clock frequency.
- The COM_ROM needs three cycles for initial access and one cycle per subsequent access.

The memory space of the embedded ROM starts at 0x4001 4000 and ends at 0x4001 BFFF.

10.3.3.2 OCM_RAM

By default, only 2K bytes are available after reset; however, the configuration can then be changed to adapt to booting/flashing, normal boot, or to any application requirement.

The device-embedded RAM has the following characteristics:

- Operates at full L3 interconnect clock frequency
- Fully pipelined, one 32-bit access per cycle
- Restricted access support, based on:
 - A region-based partitioning (see the L3 firewall description)
 - The module owner of the access, with respect to its read and write permission to that region
 - The transaction attributes of the access, with respect to the region permission properties:
 - User/supervisor
 - Code/data access

The OCM_RAM can be partitioned using the L3 firewall and used as RAM for a video frame buffer or to any application.

The RAM memory space starts at 0x4020 0000 and ends at 0x4020 FFFF.

This chapter describes the system direct memory access (SDMA) module.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

11.1 SDMA Overview

The system direct memory access (SDMA), also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The device also embeds dedicated DMA controllers: the camera image signal processor (ISP) DMA; the enhanced DMA (EDMA), which is embedded in the IVA2.2 subsystem; the display DMA; and the universal serial bus (USB) high-speed (HS) DMA. For more information, see [Chapter 6, Camera ISP Subsystem](#); [Chapter 5, IVA Subsystem](#); [Chapter 7, Display Subsystem](#); and [Chapter 22, High-Speed USB Controllers](#).

The DMA controller includes the following main features:

- Data transfer support in either direction between:
 - Memory and memory
 - Memory and peripheral device
- 32 logical DMA channels supporting:
 - Multiple concurrent transfers
 - Independent transfer profile for each channel
 - 8-bit, 16-bit, or 32-bit data element transfer size
 - Software-triggered or hardware-synchronized transfers
 - Flexible source and destination address generation
 - Burst read and write
 - Chained multiple-channel transfers
 - Endianism conversion
 - Draining
 - Linked-list support for descriptor types 1, 2, and 3
- First-come, first-serve DMA scheduling with fixed priority
- Up to 96 DMA requests
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- FIFO depth: 256 x 32-bits
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support
- Implementation of retention flip-flops (RFFs) to support dynamic power saving (DPS) between system power modes without MPU involvement

[Figure 11-1](#) shows an overview of the SDMA module.

Figure 11-1. SDMA Overview

The SDMA module has three ports - one read, one write and one configuration port - and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports. Read and write ports are multithreaded (two threads for the write port and four threads for the read port); this means that each transaction is flagged by a thread ID (0, 1, 2, or 3) in the request direction and in the response direction. This allows the read port to have four outstanding requests at a time. The write port has two threads budget available.

The MPU (or DSP) configures the SDMA controller through the L4-Core interconnect.

11.2 SDMA Environment

11.2.1 External SDMA Request Signals

The SDMA controller supports external DMA requests through the sys_ndmreq[3:0] pins. A logical channel can be configured to respond to an external synchronization request.

[Table 11-1](#) describes the external SDMA request signals.

Table 11-1. External SDMA Request Signals

Pin Name	I/O ⁽¹⁾	Description	Reset
sys_ndmreq0	I	External DMA request signal (active low)	1
sys_ndmreq1	I	External DMA request signal (active low)	1
sys_ndmreq2	I	External DMA request signal (active low)	1
sys_ndmreq3	I	External DMA request signal (active low)	1

⁽¹⁾ I = Input, O = Output

NOTE: External SDMA requests can be configured to be either edge or transition (level) sensitive by the system control module. For more information, see [Section 11.2.3, SDMA Request Scheme](#).

11.2.2 External SDMA Requests Typical Application

[Figure 11-2](#) shows the SDMA environment with an example of how to use the external hardware DMA request pins.

Figure 11-2. External SDMA Requests Typical Application

dma-005

An external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

The external DMA request signals are not available on external pins by default after cold reset. See [Chapter 13, System Control Module](#), for instructions on multiplexing out the four signal lines to pins.

11.2.3 SDMA Request Scheme

The hardware DMA request line schemes can be either edge-sensitive, or transition-sensitive.

The sensitivity selection of the **sys_ndmareq[3:0]** lines can be configured in the system control module through the following register bits:

- **CONTROL_DEVCONF0[0]** SENSDMAREQ0 register bit for **sys_ndmareq0**
- **CONTROL_DEVCONF0[1]** SENSDMAREQ1 register bit for **sys_ndmareq1**
- **CONTROL_DEVCONF1[7]** SENSDMAREQ2 register bit for **sys_ndmareq2**
- **CONTROL_DEVCONF1[8]** SENSDMAREQ3 register bit for **sys_ndmareq3**

The default scheme for the external DMA requests is transition-sensitive. Other DMA requests (coming from device internal peripherals) are transition-sensitive, except display subsystem line trigger DMA request (DSS_LINE_DMA), which is edge-sensitive.

[Figure 11-3](#) shows the DMA request captured on a falling edge in the edge-sensitive scheme.

Figure 11-3. Edge-Sensitive DMA Request Scheme

For a transition-sensitive DMA request (see [Figure 11-4](#)), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for greater than one clock cycle (CORE_L3_ICLK).

When the deassertion time is less than one clock cycle, the SDMA might not detect the deassertion.

When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.

When the channel is enabled two cycles after the DMA request is disabled, the channel does not detect the DMA request.

Figure 11-4. Transition-Sensitive DMA Request Scheme

11.3 SDMA Integration

[Figure 11-5](#) highlights the SDMA controller integration.

Figure 11-5. SDMA Controller Integration

11.3.1 Clocking, Reset, and Power-Management Scheme

11.3.1.1 Power Domain

The SDMA controller is part of the CORE power domain.

11.3.1.2 Clocking

The SDMA controller uses two clock domains:

- CORE_L4_ICLK supports the configuration port.
- CORE_L3_ICLK is both a functional clock for all internal logic and an interface clock for the two master read and write ports.

The SDMA controller supports a software-controlled standby mode with an input clock shutoff. Setting the PRCM_CM_IDLEST1_CORE[2] ST_SDMA status bit to 1 allows detection of the SDMA power mode.

For more information about power management and clock idle, see [Section 11.3.1.4, Power Management](#).

11.3.1.3 Hardware Reset

The SDMA controller is part of the CORE_RST_RET reset domain.

Hardware reset initializes all internal logic of the SDMA module, all global registers and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel.

11.3.1.4 Power Management

The SDMA module provides three methods to reduce power consumption:

- Internal clock gating (auto-idle)
- Automatic standby mode
- Idle mode

11.3.1.4.1 Internal Clock Gating (Auto-Idle)

The auto-idle power-saving mode is enabled or disabled through the [DMA4_OCP_SYSCONFIG\[0\]](#) AUTOIDLE bit. When this mode is enabled and there is no activity on the interconnect interface, the interface clock is disabled internally to the module to reduce power consumption. When there is new activity on the interconnect interface, the interface clock is restarted without any latency penalty. After reset, this mode is disabled by default. Enabling this mode is recommended to reduce power consumption.

11.3.1.4.2 Automatic Standby Mode

The module can be configured to one of the following standby modes using the [DMA4_OCP_SYSCONFIG\[13:12\]](#) MIDLEMODE bit field:

- Force-standby mode (MIDLEMODE = 0x0): The module goes into standby mode only when all the DMA channels are disabled.
- No-standby mode (MIDLEMODE = 0x1): The module never goes into standby mode.
- Smart-standby mode (MIDLEMODE = 0x2): The module enters standby mode when:
 - All DMA channels are disabled
 - OR
 - No no-synchronous channels are enabled and if hardware synchronous channels are enabled, then there should not be any hardware request asserted and there should not be any pending request in DMA4 module

11.3.1.4.3 Idle Mode

The module can be configured using the [DMA4_OCP_SYSCONFIG\[3:2\]](#) SIDLEMODE bit field to one of the following idle acknowledgement modes:

- Force-idle mode (SIDLEMODE = 0x0): The module acknowledges unconditionally the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clocks are switched off.
- No-idle mode (SIDLEMODE = 0x1): The module never acknowledges an idle request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clocks to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (SIDLEMODE = 0x2): The module acknowledges the idle request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted when all the following conditions are satisfied:
 - There is no non-synchronized channel enabled.
 - No DMA request input is asserted.
 - No pending request in the read and write port scheduler state machine.
 - All transactions are completed on all the DMA ports.
 - No interrupts are pending to be serviced.

11.3.2 Hardware Requests

11.3.2.1 SDMA Interrupts

DMA4 has four interrupt lines, numbered L_j with j=0..3. Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. The software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- [DMA4_IRQSTATUS_Lj](#) CH_31_0_L_j field shows the status of the different sources of interrupt. If the [DMA4_IRQENABLE_Lj](#) bit *i* is 1, the channel *i* is the source of interrupt in line *j*. In contrast to the [DMA4_CSRi](#) registers, the [DMA4_IRQSTATUS_Lj](#) registers are updated regardless of the corresponding bits in the [DMA4_IRQENABLE_Lj](#) registers.
- [DMA4_IRQENABLE_Lj](#) CH_31_0_L_j_EN field masks/unmasks the channel interrupt. If the [DMA4_IRQENABLE_Lj](#) bit *i* is set to 0, the channel interrupt *i* of the line *j* is masked.

Each logical channel can generate a number of different interrupt events when enabled (that is, set to 1) in the [DMA4_CICRi](#) register. Each status bit is updated in the [DMA4_CSRi](#) register only when the corresponding enable bit is enabled in the [DMA4_CICRi](#) register.

To determine an interrupt source when an interrupt rises on an interrupt line L_j, you must:

- Identify the channel (LCH_i) generating the interrupt.
Read the [DMA4_IRQSTATUS_Lj.LCHi](#) (LCH0 to LCH31). If LCH_i = 1, channel *i* is the originator of the interrupt.
- Identify the interrupt event.
Read the LCH_i [DMA4_CSRi](#). For example, if the drop event (the [DMA4_CSRi\[1\]](#) DROP bit) is 1, there will be a request collision.

The interrupt event status bit in the [DMA4_CSRi](#) register is immediately reset after it is written to 1.

The interrupt status bit in the [DMA4_IRQSTATUS_Lj](#) register is cleared after it is written to 1.

[Table 11-2](#) shows the SDMA interrupts.

Table 11-2. SDMA Interrupts

Source	IRQ to MPU INTC	IRQ to IVA2.2 INTC	Description
SDMA_IRQ_0	M_IRQ_12	EVT89	SDMA interrupt request 0
SDMA_IRQ_1	M_IRQ_13	EVT90	SDMA interrupt request 1
SDMA_IRQ_2	M_IRQ_14	N/A	SDMA interrupt request 2
SDMA_IRQ_3	M_IRQ_15	N/A	SDMA interrupt request 3

11.3.2.2 DMA Requests to the SDMA Controller

All peripherals internal to the device use the transition-sensitive scheme for DMA requests. For more information on the transition-sensitive scheme, see [Section 11.2.3, SDMA Request Scheme](#). [Table 11-3](#) lists the SDMA request mapping.

Table 11-3. SDMA Request Mapping

11.4 SDMA Functional Description

The SDMA module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 11-6 shows the SDMA controller top-level block diagram.

Figure 11-6. SDMA Controller Top-Level Block Diagram

dma-006

11.4.1 Logical Channel Transfer Overview

As Figure 11-6 shows, the SDMA module has one read port and one write port operating independently of each other. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization

A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.

- Logical channel activation

A logical channel becomes active as follows:

- For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
- For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel
- Logical channel transfer composition

A DMA transfer is divided automatically into a number of transactions. Depending on the logical channel context configured, transfer size, the start address alignment, the addressing mode, and the configured maximum burst size, each transaction can be either a single access or a burst of accesses.

- Logical channel scheduling

When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bit in the logical channel [DMA4_CCRI](#) register determines if a logical channel is queued as high or low priority. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register ([DMA4_GCR](#)).

NOTE: The [DMA4_GCR\[23:16\]](#) ARBITRATION_RATE field is not dependent on the [DMA4_GCR\[13:12\]](#) HI_THREAD_RESERVED field. The ARBITRATION_RATE field is dependent on the [DMA4_CCRI\[26\]](#) WRITE_PRIORITY bit and the [DMA4_CCRI\[6\]](#) READ_PRIORITY bit.

- Read/write port access scheduling policy

When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during its block transfer.

The SDMA module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting.
- At least one free thread ID is available.

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

NOTE: If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

When only one channel is enabled, only one thread is allocated for the channel. In such a situation the channel can have maximum of 4 outstanding commands (without getting the responses) without rescheduling the channel at the end of each transaction. Each command can be either single access (8-bit, 16-bit or 32-bit) or burst access (2 x M, 4 x M, 8 x M or 16 x M, where M can be 8-bit, 16-bit or 32-bit).

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see [Section 11.4.12, Interrupt Generation](#)).

11.4.2 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the [DMA4_GCR](#) register. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) -1.

11.4.3 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements, and each element can have a size of 8, 16, or 32 bits, as follows:

$$\text{transfer block size} = \text{number of frames} \times \text{number of elements per frame} \times \text{element size}$$

The FN, number of elements per frame (EN), and size of elements are common for both the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the element size (ES), even across consecutive frames.
- Single-index: The address increases by the ES, plus the element index (EI) value minus one (even across consecutive frames).
- Double-index: The address increases by the ES, plus the EI value minus one within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI should be such that, when added to the logical channel address pointer, results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

NOTE: The source and destination start addresses must also be aligned on an ES boundary.

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and a misaligned address error interrupt occurs, if enabled (see [Section 11.4.12, Interrupt Generation](#)).

The [DMA4_CFNI](#) register configures the FN in a block.

The [DMA4_CENI](#) register configures the EN.

The [DMA4_CSDPI](#) register configures the ES.

The DMA4_CSSAi and DMA4_CDSAi registers configure the source and destination start addresses.

The DMA4_CCRi register configures the source and destination addressing modes.

The DMA4_CSEi, DMA4_CSFi, DMA4_CDEi, and DMA4_CDFi registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n+1) = A(n)$$

Equation 2. Post-increment addressing:

$$A(n+1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n+1) = A(n) + ES + (EI - 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter $\neq 0$):

$$A(n+1) = A(n) + ES + (EI - 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter $\neq 0$):

$$A(n+1) = A(n) + ES + (FI - 1)$$

Calculate the element and frame index as follows:

Equation 5. Element index

$$EI = [(Stride\ EI - 1) * ES] + 1$$

Equation 6.. Frame index

$$FI = [(Stride\ FI - 1) * ES] + 1$$

where:

A(n): Byte address of the element n within the transfer.

ES is in bytes, $ES \in \{1, 2, 4\}$.

EI is in bytes, specified in a configuration register, $-32768 \leq EI \leq 32767$.

Stride EI: The difference in the number of elements between the start of the current element, n, to the start of next element, n+1.

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, DMA4_CENi.

FI is in bytes, specified in a configuration register, $-2147483648 \leq FI \leq 2147483647$.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, DMA4_CFNI.

Figure 11-7 shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90Degrees clockwise image rotation example shown in **Figure 11-11**.) The double-index addressing example shown in **Figure 11-7** has ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

Figure 11-7 through **Figure 11-10** show examples of addressing mode configurations. **Table 11-4** lists parameter values for the examples.

Figure 11-7. Example Showing Double-Index Addressing, Elements, Frames, and Strides

dma-007

Figure 11-8. Addressing Mode Example (a)

dma-008

Figure 11-9. Addressing Mode Example (b)

dma-009

Figure 11-10. Addressing Mode Example (c)

dma-010

Table 11-4. Parameter Values for Addressing Mode Examples (a), (b), and (c)

Parameter	Example (a)	Example (b)	Example (c)
Addressing mode	Single index (or post-increment)	Double index	Double index
Start address	0	0	8
ES	4 (32-bit)	4 (32-bit)	2 (16-bit)
EN	3	2	2
EI	1	5	1
FN	1	2	2
Frame index	N/A	5	-9

Double indexing can occur either on source (read) or destination (write). Equations for rotation of xx degrees on destination are obtained by taking equations for rotation of (360-xx) degrees on source, and swapping x and y in them. The opposite is also true. [Table 11-5](#) list the equations for rotation for 90, 180 and 270°.

Table 11-5. Equations for Rotation

		90° Rotation	180° Rotation	270° Rotation
Double indexing on destination (write)	Base address	$ES \cdot (y-1)$	$ES \cdot (x \cdot y - 1)$	$ES \cdot y \cdot (x-1)$
	Element index (EI)	$ES \cdot (y-1) + 1$	$1 - 2 \cdot ES$	$1 - ES \cdot (y+1)$
	Frame index (FI)	$1 - ES \cdot [(x-1) \cdot y + 2]$	$1 - 2 \cdot ES$	$1 + ES \cdot (x-1) \cdot y$
Double indexing on source (read)	Base address	$ES \cdot x \cdot (y-1)$	$ES \cdot (x \cdot y - 1)$	$ES \cdot (x-1)$
	Element index (EI)	$1 - ES \cdot (x+1)$	$1 - 2 \cdot ES$	$ES \cdot (x-1) + 1$
	Frame index (FI)	$1 + ES \cdot (y-1) \cdot x$	$1 - 2 \cdot ES$	$1 - ES \cdot [(y-1) \cdot x + 2]$

[Table 11-6](#) and [Figure 11-11](#) show the configuration required to perform a 90° clockwise image rotation of a 240 x 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line by line starting at the left-hand end of the top line.

NOTE: The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

Rotations:

[Section 11.5.7, 90° Clockwise Image Rotation](#), describes how to program this example.

Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

Table 11-6. Example Parameter Values for a 90° Clockwise Image Rotation

Parameter	Source Value	Destination Value
Bits per pixel	32	32
ES	4	4
Image width	SW	SH
Image height	SH	SW
Stride elements (stride EI)	1 element	SH
Stride frames (stride FI)	1 element	$-[(SW-1)*SH+1] = -38241$ elements
Start address	0x100000	$0x200000 + (SH - 1) \times ES = 0x20027C$
EN	SW	SW
EI	$[(Stride EI - 1) * ES] + 1 = 1$	$[(Stride EI - 1) * ES] + 1 = 637$
FN	SH	SH
FI	$[(Stride FI - 1) * ES] + 1 = 1$	$[(Stride FI - 1) * ES] + 1 = -152967$

Figure 11-11. Example of a 90° Clockwise Image Rotation

11.4.4 Packed Accesses

When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (that is, post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access may be maximized by specifying that the source or destination is packed through the channel [DMA4_CSDPi](#) register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (four elements per access) and 16 bits (two elements per access).
- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access might be only partially filled. This is indicated to the source or destination using the byte-enable signals.

11.4.5 Burst Transactions

Transfer performance can be improved, where the source or destination and addressing profile supports it, by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equivalent to 16, 32, or 64 bytes through the [DMA4_CSDPi](#) register, with the read burst size being programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses should be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

NOTE: Except in the constant addressing mode, the source or destination must be specified as packed for burst transactions to occur.

11.4.6 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the [DMA4_CSDPi](#) register for the particular logical channel. If the endianism of the source and destination differ, and the logical channel ES is less than the SDMA module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that is equal to the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to inform the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel [DMA4_CSDPi](#) register.

11.4.7 Transfer Synchronization

A logical channel can be programmed for either software-triggered or hardware synchronized transfers.

11.4.7.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA register bits [DMA4_CCRI\[4:0\]](#) and [DMA4_CCRI\[20:19\]](#) to 0. The transfer starts as soon as the DMA register bit [DMA4_CCRI\[7\]](#) is set (that is, enters the scheduling process).

11.4.7.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from either the source or destination target. A hardware synchronized transfer is specified by configuring the DMA request line number in the channel [DMA4_CCRI](#) register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see [Table 11-8](#)).

Specify the DMA request number in the channel DMA register bits **DMA4_CCRI[4:0]** and **DMA4_CCRI[20:19]**. After the DMA register bit **DMA4_CCRI[7]** is set, the logical channel becomes enabled but not activated (that is, it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

NOTE: DMA Request Line

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

The channel synchronization control registers are 1-based. For example, to enable the **S_DMA_1** request, **DMA4_CCRI[4:0]** SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel **DMA4_CCRI** register and the DMA register bits **DMA4_CCRI[5]** and **DMA4_CCRI[18]**, respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by Data_type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independent of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify size of the packet.

To support the burst mode, the logical channel must also be configured to use the target-port packed access mode.

The packet size is configured based on the source/destination synchronization select bit in the **DMA4_CCRI** register through either the channel DMA4_CDFi register (source synchronized) or the DMA4_CSFi register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

$$\text{Block_size} = \text{Number_of_Frame_in_Block} * \text{Number_of_Element_in_Frame} * \text{Element_Size}$$

- Synchronized at the source

The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see [Section 11.4.11, Reprogramming an Active Channel](#)).

For a source synchronized transfer, buffering can be enabled or disabled by setting the **DMA4_CCRI[25]** BUFFERING_DISABLE bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic

packed/burst write transaction (assuming the address is packed/burst aligned).

NOTE: Regardless of whether buffering is enabled or not, buffering is not performed between frames. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split into optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel DMA register bit [DMA4_CCRI\[23\]](#). Data is prefetched on the read port side in advance of the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see [Section 11.4.2, FIFO Queue Memory Pool](#)).

Buffering disable is not allowed for a destination-synchronized transfer.

NOTE: Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Whether buffering is enabled or disabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the WRITE_MODE bit field of the [DMA4_CSDPi](#) register = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering disable is enabled or disabled, the packet interrupt is not generated in the packet source synchronized mode.

CAUTION

The BUFFERING_DISABLE bit field of the [DMA4_CCRI](#) register must be filled with an allowed value, as specified in [Table 11-7](#).

Table 11-7. Buffering Disable

BUFFERING_DISABLE		
(0: buffering enable, 1: buffering disable)		
Destination synchronized	0	Allowed
	1	Not allowed
Source synchronized	0	Allowed
	1	Allowed

Synchronized transfer monitoring using CDAC ([DMA4_CDACi](#)):

Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.

The CDAC register is writable; thus, you can initialize the CDAC to monitor the transfer and determine if the transfer is started or not (see [Section 11.5.4, Synchronized Transfer Monitoring Using CDAC](#), for more information).

NOTE: For 16-bit transactions, start reading from or writing to the LSByte first to enable the register update. This is not an issue for 32-bit read-write transactions.

11.4.8 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the concurrent channel number is superior to the number of available threads.

NOTE: Four threads are available on the read port, and two threads are available on the write port.

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see [Section 11.5.5](#)):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set on the global register [DMA4_GCR\[13:12\]](#).

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the [DMA4_GCR \[13:12\]](#) value, the following threadID on the read/write ports are reserved for a high-priority channel:

Read port priority thread reservation:

- [DMA4_GCR\[13:12\] = 0x0](#) => No ThreadID is reserved for high-priority channels.
- [DMA4_GCR\[13:12\] = 0x1](#) => Read ThreadID 0 is reserved for high-priority channels.
- [DMA4_GCR\[13:12\] = 0x2](#) => Read ThreadID 0 and Read ThreadID 1 are reserved for high-priority channels.
- [DMA4_GCR\[13:12\] = 0x3](#) => Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are reserved for high-priority channels.

Write port priority thread reservation:

- [DMA4_GCR\[13:12\] = 0x0](#) => No ThreadID is reserved for high-priority channels
- [DMA4_GCR\[13:12\] = 0x1](#) => Write ThreadID 0 is reserved for high-priority channels.
- [DMA4_GCR\[13:12\] = 0x2](#) => Write ThreadID 0 is reserved for high-priority channels.
- [DMA4_GCR\[13:12\] = 0x3](#) => Write ThreadID 0 is reserved for high-priority channels.

Regardless whether or not the enabled channels are of high priority, only the setting of the [DMA4_GCR\[13:12\]](#) value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit [DMA4_CCRi\[26\]](#) is added for write priority, and the previous priority bit becomes read priority bit [DMA4_CCRi\[6\]](#).

NOTE: The device has one priority bit per logical channel, not one per port.

11.4.9 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the [DMA4_GCR](#) register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the [DMA4_GCR\[15:14\]](#) HI_LO_FIFO_BUDGET field. The maximum channel FIFO depth is limited by the HI_LO_FIFO_BUDGET field as follows:

If the channel is low priority:

- When HI_LO_FIFO_BUDGET = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When HI_LO_FIFO_BUDGET = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user is responsible for performing the following equation:

- For a high-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of High Channel <= High Budget FIFO
- For a low-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of Low Channel <= Low Budget FIFO

NOTE: Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

11.4.10 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel **DMA4_CLNK_CTRLi** register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it might be all, none, or just the first one). The DMA request line number should be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the **DMA4_CLNK_CTRLi[15]** ENABLE_LNK bit. The looping transfer stops after the specified channel transfer is complete.

NOTE: DMA Request Line

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

For more information on the programming model, see [Section 11.5, SDMA Basic Programming Model](#).

11.4.11 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the **DMA4_CCRI[7]** ENABLE bit. When any ongoing transaction is complete and the read-active and write-active bits in the **DMA4_CCRI** register (**DMA4_CCRI[9]** RD_ACTIVE and **DMA4_CCRI[10]** WR_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

11.4.12 Interrupt Generation

The SDMA module has four interrupt request output lines, SDMA_IRQ_0 to SDMA_IRQ_3. One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in [Table 11-8](#) occurs.

Table 11-8. Logical DMA Channel Events

Event	Description
End of packet	A packet transfer completed.
End of block	A block transfer completed.
End of frame	A frame transfer completed.
End of super block	A super block transfer completed.
Half of frame	Half of the current frame transferred.
Start of last frame	The first element of the last frame transferred.
Transaction error	A transaction error returned by the interconnect in either the read or write port.
Address error	An attempt was made to perform a DMA access to an address not aligned on an ES boundary. Condition to occur: if DMA4_CEN[23:0] CHANNEL_ELMNT_NBR = 0x000000 or DMA4_CFN[15:0] CHANNEL_FRAME_NBR = 0x0000 or DMA4_CSDP[1:0] DATA_TYPE = 0x3.
Supervisor transaction error	An error occurred, for example, when an unauthorized initiator (that is not a supervisor) tries to use a supervisor transfer.
Drain end	Drain is completed (DMA4_CCRi[10] WR_ACTIVE becomes 0).
Drop error	A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced.

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the [DMA4_IRQENABLE_Lj](#) register (where j is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel [DMA4_CICRi](#) register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the [DMA4_IRQSTATUS_Lj](#) register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel [DMA4_CSRi](#) register.

11.4.13 Packet Synchronization

A packet transfer notion is related to the behavior of some peripheral, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

`maximum_transfer_size = peripheral_FIFO_depth x number_of_frame_in_block.`

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on RD port or WR port if source target or destination target is packet synchronized respectively.

Example:

Let's consider a camera interface, which have a FIFO_depth of 128 Words and a FIFO_element_number_threshold of 128 and a picture to transfer with a size 320 lines per 240 columns. If frame synchronization is associated to each DMA request then the maximum transfer size that can be performed is 128×2^{16} words. In this case, a frame is 128 words long, which does not fit the size of a line. Then it's not possible to generate an interrupt at the end of line. However with introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size (`maximum_transfer_size = $2^{24} \times 2^{16}$ words`) is independent of both `peripheral_FIFO_depth` and `FIFO_element_number_threshold`. This allows, making an enough long transfer within one channel context and perform rotation operation on big image format.

The main features of DMA Packet transfer are as follows:

- DMA Packet_Data_Size for each DMA Request: typically this will be Peripheral_element_number_threshold Number of elements in a packet shares the [DMA4_CSFI](#) and [DMA4_CDFI](#) configuration registers. Indeed if the peripheral is the source target, respectively destination target, that means the used addressing mode is constant, consequently [DMA4_CSFI](#)[15:0], respectively [DMA4_CDFI](#)[15:0], is used to specify the packet data size (PKT_ELNT_NBR) and the bit fields [31:16] are unused. To specify the Packet data size in the [DMA4_CSFI](#) or [DMA4_CDFI](#), the user must set the [DMA4_CCRI](#)[24] SEL_SRC_DST_SYNC respectively to 1 or 0.

NOTE: The packet size can be a sub-multiple or non sub-multiple of a frame size. If DMA Packet_Data_Size is aligned on DMA channel block data size boundary, DMA will transfer the last data in channel block boundary and stop at block boundary for the last packet DMA request. If the Packet_Data_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

- DMA Packet_Data_Transfer does not affect DMA channel capabilities in term of packing and bursting.

The Packet synchronization mode is active when [DMA4_CCRI](#)[5] FS = [DMA4_CCRI](#)[18] BS = 1. Then

- if [DMA4_CCRI](#)[24] SEL_SRC_DST_SYNC=0; [DMA4_CDFI](#)[15:0] gives the number of element in packet and [DMA4_CDFI](#)[31:16] is unused for the packet size.
- if [DMA4_CCRI](#)[24] SEL_SRC_DST_SYNC=1; [DMA4_CSFI](#)[15:0] gives the number of element in packet and [DMA4_CSFI](#)[31:16] is unused for the packet size.

NOTE: The maximum transfer size, regardless of the packet size, is always: Block_size = Number_of_Frame_in_Block x Number_of_Element_in_Frame x Element_Size. If the DMA channel packet/burst access is across packet boundary, DMA hardware automatically splits this packing/burst access into multiple smaller accesses, which will be aligned on packet boundary. Otherwise, the DMA transfers data as usual packing/burst access.

11.4.14 Graphics Acceleration Support

The SDMA supports two graphic acceleration features:

- Transparent copy
- Constant fill

Only one of these features can be enabled at any given time through the [DMA4_CCRI](#) register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the [DMA4_COLORI](#) register, so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination, but instead leaves the data in the corresponding location in the destination as it is.

Figure 11-12 shows the 2-D graphic transparent color block diagram.

Figure 11-12. 2-D Graphic Transparent Color Block Diagram

The constant fill feature provides the ability to specify a particular color through the [DMA4_COLOR](#) register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8 bpp (bits per pixel), 16 bpp, and 24 bpp, depending on what is specified as the DMA transfer ES via the [DMA4_CSDP](#)_i register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the most-significant 8 bits ([31:24]) are 0. Both features are compatible with packed and burst transactions.

11.4.15 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the corresponding bits in the channel [DMA4_CC](#)_i register. This must be done using supervisor access. Once a channel is configured in supervisor mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

11.4.16 Posted and Nonposted Writes

A logical channel can be configured in its DMA register bits [DMA4_CSDP](#)_i[17:16] to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.
- Posted write: Transfer continues without waiting for each write to complete (might improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write is completed before transfer can complete.

11.4.17 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel will undergo an abort, except if the channel was hardware source synchronized with buffering Enabled ([DMA4_CC](#)_i[25] BUFFERING_DISABLE='0'). In that case, the fifo will be drained in order to avoid losing data. See [Section 11.4.18](#) for details on this feature.

11.4.18 FIFO Draining Mechanism

When a source synchronized channel is disabled during a transfer, then the current hardware request (element/packet/frame/block) service is completed and the channel [DMA4_CC](#)_i[9] RD_ACTIVE bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the [DMA4_CCRI\[10\]](#) WR_ACTIVE bit is set to 0 (channel is no more active on the write port) and if the [DMA4_CICRI\[12\]](#) DRAIN_END_IE is set to 1, the status bit [DMA4_CSRI\[12\]](#) DRAIN_END is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it needs to wait for [DMA4_CCRI\[9\]](#) RD_ACTIVE and [DMA4_CCRI\[10\]](#) WR_ACTIVE to become '0' before being re-enabled for a new transfer. The FIFO drain for a channel will happen only in the following cases:

- If the channel is a source synchronized channel and [DMA4_CCRI\[25\]](#) BUFFERING_DISABLE='0' and
- If the channel is not a solid fill channel and
- If the channel is not a transparent and copy channel

NOTE: In case of a self-linked or chain-linked channel, it is user responsibility to disable the [DMA4_CLNK_CTRL\[15\]](#) ENABLE_LINK bit before disabling the channel.

In all other cases, the channel will undergo an abort.

NOTE: If the channel intended to be used is a drain candidate, always enable DRAIN END INTERRUPT for that channel.

When the sDMA is in smart standby mode, before disabling a drain candidate channel ([DMA4_CCRI\[7\]](#) ENABLE = 0x0), the sDMA must be configured to be in force standby mode ([DMA4_OCP_SYS CONFIG\[13:12\]](#) = 0x0) or in no standby mode ([DMA4_OCP_SYS CONFIG\[13:12\]](#) = 0x1). After the occurrence of DRAIN END INTERRUPT EVENT from that channel, the sDMA can be switched back to smart standby mode ([DMA4_OCP_SYS CONFIG\[13:12\]](#) = 0x2).

11.4.19 Linked List

11.4.19.1 Overview

The SDMA supports the logical transfer descriptor loader feature. A transfer descriptor represents a set of values that maps to a set of logical channel configuration registers.

A logical channel transfer descriptor can be loaded by DMA from memories, then successive transfer descriptors can be autonomously loaded according to a linked-list scheme. This enables DMA4 scatter gather transfers with minimum MPU support by removing successive channel configuration processing and the associated interrupt handling overheads. It also optimizes DMA4 channel resources by enabling efficient transfer serialization on a single logical channel versus concurrent (multiple) logical channel use.

Different types of transfer descriptors are supported (full or partial logical channel configuration registers are set). This optimizes the memory size required for storing a long linked list, because parameter changes are limited to only a few logical channel configuration registers.

11.4.19.2 Link-List Transfer Profile

A linked-list transfer can be seen as a super-block transfer (where the block is composed of FN frames and each frame includes EN elements). In a super block. The block size (FN x EN x ES) can be changed in the linked list by loading an updated transfer descriptor.

The end of the super block is signaled in the last descriptor associated with the last block. Generally, for a given link-list transfer, the logical channel is set at the beginning of the transfer and the logical channel configurations for the subsequent blocks are slightly changed. Thus, the descriptor can be limited to an update of only few parameters, like FN or EN. This assumes that the content of unmodified registers is preserved when a new descriptor is loaded.

A transfer descriptor is composed of a set of channel configuration register values with the addition of the next-descriptor pointer register ([DMA4_CNDPI](#)) and a channel-descriptor parameter register ([DMA4_CDPi](#)). The next-descriptor pointer is the 32-bit address pointer from where the next transfer descriptor is to be loaded.

Using the next-descriptor pointer, the user can also stop a link-list transfer by setting the DMA4_CNDPi[31:2] NEXT_DESCRIPTOR_POINTER bit field of the last descriptor to 0x3FFF FFFF (that is, setting the DMA4_CNDPi[31:0] bit field to 0xFFFF FFFC).

CAUTION

The setting of the DMA4_CNDPi[31:2] NEXT_DESCRIPTOR_POINTER bit field must be done only through the descriptor load (that is, only from the descriptor content). This is because once the channel is configured and enabled, it is not recommended to change the configuration through configuration port access. However, if there are no descriptors in the link-list chain, but still making the channel a descriptor (type 1, 2, 3) candidate, the user can configure the value 0x3FFF FFFF into the DMA4_CNDPi[31:2] NEXT_DESCRIPTOR_POINTER bit field (0xFFFF FFFC into DMA4_CNDPi[31:0]) through configuration port access.

11.4.19.3 Descriptors

A transfer descriptor is a set of values that maps to a set of logical channel configuration registers. Such a descriptor contains the parameters associated with a transfer profile (transfer size, source or destination addresses, etc). Four different types of transfer descriptors are supported to optimize the memory size required to store a long linked list, and to minimize MPU use to create and maintain the descriptor list.

A transfer descriptor is a list of 32-bit values. A descriptor must be 32-bit-aligned in memory. Only the 30 least-significant bits (LSBs) of the next-descriptor address pointer are updated from the descriptor, and the DMA4 forces the 2 LSBs to 0 on the generation of the pointer address. The descriptor size, which is variable, depends on the descriptor type and the Nxt_Dv and Nxt_Sv bit fields.

Transfer descriptor bit mapping is the same as DMA4 logical-channel configuration register bit mapping, with the following exceptions:

- Src_Element_index and Dst_Element_index are concatenated in the same 32-bit location.
- [DMA4_CICRi](#) (interrupt event mask)
- CFN (frame number)
- Bit fields:
 - P: Corresponds to the PAUSE_LINK_LIST bit:
 - When set to 1 in the descriptor, the channel is suspended when the descriptor load completes.
 - The user must not set this bit to 1 through the configuration port. Otherwise, behavior is undefined.
 - When set to 0 (through configuration port) after pause, the linked-list channel resumes its transfer (either descriptor load or data load).
 - B: Corresponds to the end-of-block enable bit (BLOCK_IE) of the [DMA4_CICRi](#) register. Valid only for type 3. This value is don't care for descriptor types 1 and 2 where [DMA4_CICRi](#) is fully specified.
 - Nxt_Dv, Nxt_Sv: Mapped in the [DMA4_CDPI](#) register. They indicate one of the following possibilities:
 - Next descriptor contains an updated destination or source address.
 - Next descriptor does not update the source or destination address, but increments the last source or destination address (from the end of the last transfer).
 - The next source address and/or destination address are the last valid ones in the configuration memory. This means that the corresponding location in the configuration memory is not updated (assuming that they were initialized at least once in the past). This is also called wrapping addressing.
 - Next_Descriptor_Type: Specify the next descriptor type that corresponds to the NEXT_DESCRIPTOR_TYPE bit field in the [DMA4_CDPI](#) register.

11.4.19.3.1 Type 1

A type 1 descriptor includes the overall channel configuration register value to be loaded (global registers are not part of the type 1 descriptor). This descriptor is used primarily when major changes are required:

- Channel read or write access profiles must be modified, for instance, for bursting and packing (included in the [DMA4_CSDPi](#) register).
- Attach a new DMA request to the same channel or change the priority (included in the [DMA4_CCRI](#) register).
- Enable solid or transparent color fill (included in the [DMA4_CCRI](#) and [DMA4_COLORI](#) registers).
- Enable a channel link (included in the [DMA4_CLNK_CTRLi](#) register).

[Table 11-9](#) shows a type 1 descriptor.

Table 11-9. Type 1

	3 1	3 0	2 9	2 8	2 7	2 6	2 5	2 4	2 3	2 2	2 1	2 0	1 9	1 8	1 7	1 6	1 5	1 4	1 3	1 2	1 1	1 0	9 8	8 7	7 6	6 5	5 4	4 3	3 2	2 1	1 0

11.4.19.3.2 Type 2

A type 2 descriptor includes the overall logical channel transfer address register and transfer format register to be loaded. This descriptor enables 2D addressing linked-list transfer (for example, a multimedia application where 2D objects are moved in a link). [Table 11-10](#) shows a type 2 descriptor with source and destination address updates. [Table 11-11](#) shows a type 2 descriptor with one source or destination address update.

Table 11-10. Type 2 With Source and Destination Address Updates

Table 11-11. Type 2 With Source or Destination Address Update

11.4.19.3.3 Type 3

A type 3 descriptor is limited to a few logical channel transfer address registers and transfer format registers to be loaded. This descriptor enables simple 1D addressing link transfer (for example, scatter-gather or ping-pong memory movement using a linked list). [Table 11-12](#) shows a type 3 descriptor with source and destination address updates. [Table 11-13](#) shows a type 3 descriptor with one source or address destination update.

11.4.19.4 Linked-List Control and Monitoring

11.4.19.4.1 Transfer Mode Setting

Four descriptor types are available in [DMA4_CDPI\[9:8\]](#) TRANSFER_MODE to distinguish the different transfer modes:

- [DMA4_CDPI\[9:8\]](#) TRANSFER_MODE = 00: The current channel is using normal mode.
- [DMA4_CDPI\[9:8\]](#) TRANSFER_MODE = 01: The current channel is using link-list channel mode for a type 1, 2, or 3 descriptor.

The reset value is Normal mode ([DMA4_CDPI\[9:8\]](#) TRANSFER_MODE = 0).

11.4.19.4.2 Starting a Linked List

Like a nonlinked-list transfer, a link transfer starts under host control by enabling the associated logical channel (set the [DMA4_CCRI\[7\]](#) ENABLE bit to 1). The [DMA4_CDPI\[10\]](#) FAST bit sets the start mode of the link-list transfer:

In nonfast-start mode, the logical channel configuration is fully initialized so that the transfer can start without descriptor loading.

In fast-start mode, the descriptor pointer and other inputs are given. The channel starts by loading the descriptor and then starts the data transfer phase.

11.4.19.4.3 Monitoring a Linked-List Progression

In addition to the [DMA4_CCENi](#) (remaining elements) and [DMA4_CCFNi](#) (remaining frames) registers that are used to monitor the transfer progress, a per-channel register, [DMA4_CCDNi](#) (channel current active descriptor number), monitors which descriptor in the list is active. The user must initialize the [DMA4_CCDNi](#) register to 0 during the initial configuration. When the [DMA4_CCDNi](#) register is updated, the [DMA4_CCFNi](#) and the [DMA4_CCENi](#) registers are updated. The user must also initialize the [DMA4_CCFNi](#) and [DMA4_CCENi](#) registers to 0xFFFF and to 0xFFFF, respectively, to track the effective transfer start of synchronized transfer.

11.4.19.4.4 Interrupt During Linked-List Execution

Any logical channel source of interrupt can be triggered during a linked-list execution, if the interrupt source is enabled, during the initial configuration in CICR. The [DMA4_CICRI](#) register can also be updated during the linked-list execution if descriptor types 1 and 2 are used.

The use of an interrupt event in a link execution can be difficult, because the link can progress in parallel with interrupt service routine (ISR) execution. This makes it difficult to synchronize them unless system assumptions are used. The most appropriate synchronization model is to get an interrupt-only on linked-list completion, when the last transfer block is complete. This prevents the interrupt from occurring during the link execution. An end-of-super-block interrupt event available in the [DMA4_CICRI](#) and [DMA4_CSRI](#) registers can be enabled at initial configuration or when using descriptor types 1 and 2. To prevent the use of descriptor type 1 or 2 to update BLOCK_IE (full [DMA4_CICRI](#) update), a dedicated BLOCK_IE bit field is also available in a type 3 descriptor.

11.4.19.4.5 Pause a Linked List

When the channel is suspended, it remains enabled.

The pause behaves differently, depending on the transfer mode:

- Normal transfer mode: If the user sets the **DMA4_CDPI[7]** PAUSE_LINK_LIST bit to 1, the channel completes the current read and write transactions and then suspends the channel. The channel can be resumed by setting the channel **DMA4_CDPI[7]** PAUSE_LINK_LIST bit to 0.
- Linked-list type 1, 2, or 3 mode: The user must not set the **DMA4_CDPI[7]** PAUSE_LINK_LIST bit through the configuration port; otherwise, transfer behavior is undefined.

A PAUSE_LINK_LIST bit (P) is set to 1 in the descriptor.

- The channel is suspended after the descriptor load, translation, and configuration memory update are complete.
- The linked list can be resumed by resetting the **DMA4_CDPI[7]** PAUSE_LINK_LIST bit (through the configuration port).

11.4.19.4.6 Stop a Linked List (Abort or Drain)

The channel can be stopped in case of a drain or an abort. These cases are exclusive.

11.4.19.4.6.1 Drain

- Drain conditions:
A channel is a drain candidate if it is a hardware-source-synchronized transfer with [DMA4_CCRI\[25\]](#) BUFFERING_DISABLE = 0 and channel should not be doing any of the graphics operation (transparent copy or solid-color fill).
- Drain trigger:
A drain candidate channel is drained if it is disabled. ([DMA4_CCRI\[7\]](#) ENABLE = 0) or if it receives a transaction error on the read port.
- Drain behavior with a type 1, 2, or 3 descriptor. Drain trigger can occur in two situations:
 - During descriptor loading: Any ongoing current transaction is complete and the channel is aborted.
 - During data loading: The read is completed at the boundary of the request (element/frame/packet/block boundary), the FIFO is drained to the destination, and then a DRAIN_END interrupt can be asserted.

11.4.19.4.6.2 Abort

- Abort condition:
A channel is an abort candidate if it is software-synchronized, hardware-destination-synchronized, solid color-fill, transparent-color fill, or hardware-source-synchronized with [DMA4_CCRI\[25\]](#) BUFFERING_DISABLE = 1.
- Abort trigger:
A channel is an abort candidate if it is disabled. ([DMA4_CCRI\[7\]](#) ENABLE = 0), if it receives a transaction error on the read or write port, or if there is a MISALIGNMENT_ERROR.
- Abort behavior with a type 1, 2, or 3 descriptor:
If an abort trigger occurs, the channel aborts immediately after completion of current read/write transactions and then the FIFO is cleaned up.
In type 1, 2, or 3, if an abort trigger or drain trigger occurs during the descriptor load phase, the channel aborts.

11.4.19.4.7 Status Bit Behavior

This section describes the behavior of the [DMA4_CSRI\[6\]](#) SYNC, [DMA4_CCRI\[9\]](#) RD_ACTIVE and [DMA4_CCRI\[10\]](#) WR_ACTIVE status bits:

- For a hardware-synchronized channel in linked-list mode, the [DMA4_CSRI\[6\]](#) SYNC bit becomes active ([DMA4_CSRI\[6\]](#) SYNC = 1) when the first data load transaction is scheduled and remains active until the last data load transaction in the block (not super block) is descheduled ([DMA4_CSRI\[6\]](#) SYNC = 0). The SYNC bit is not active during the descriptor load phase.
- The [DMA4_CCRI\[9\]](#) RD_ACTIVE bit is active during the data load phase and the descriptor load phase. It becomes active when the first read transaction is scheduled. It becomes inactive:
 - When (during the descriptor load phase) the last descriptor write request is descheduled
 - When (during the data load phase) the last read transaction in the block (not super block) is descheduled for software-synchronized transfer or destination-synchronized transfer with prefetch enabled
 - When (during the data load phase) the last read transaction in the request (element/frame/packet/block sync) is descheduled for hardware-source-synchronized transfer or hardware-destination-synchronized transfer without prefetch
- The [DMA4_CCRI\[10\]](#) WR_ACTIVE bit is active only during the data load phase. It becomes active when the first write transaction is scheduled and becomes inactive:
 - Until the last write transaction in the block (not super block) is descheduled and the FIFO is cleaned up for software-synchronized transfer

- Until the last write transaction in the request (element/frame/packet/block sync) is descheduled and the FIFO is cleaned up for hardware-source-synchronized transfer (with DMA4_CCR[25] BUFFERING_DISABLE = 0) or hardware-destination-synchronized transfer.

11.4.19.4.8 Linked-List Channel Linking

Channel linking for inter and intra super block is supported for type 1, 2, and 3 descriptors.

Assume that CHx and CHz are linked-list channels using generic descriptors. If CHx is composed of N descriptors and CHz is composed of M descriptors, then in nonfast mode,

CHx: CHx[Data1]->CHx[DES1] -> -> CHx[DESN]->CHx[DataN + 1]

CHz: CHz[Data1]->CHz[DES1] -> -> CHz[DESM]->CHz[DataM + 1]

It is possible to link CHx to CHz or CHx to itself after the completion of the CHx transfer (end of super block). To do this, the user must set the DMA4_CLNK_CTRL[15] ENABLE_LNK bit to 1 and the DMA4_CLNK_CTRL[4:0] NEXTLCH_ID bit to z (or to x for self linking) through the last descriptor using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]->CHx[DES1] -> -> CHx[DESN]->CHx[DataN+1] -> CHz: CHz[Data1]->CHz[DES1] -> -> CHz[DESM]->CHz[DataM+1]

It is also possible to link CHx to CHz during the CHx transfer and before the end of super block. The user must set the DMA4_CLNK_CTRL[15] ENABLE_LNK bit to 1 and the DMA4_CLNK_CTRL[4:0] NEXTLCH_ID bit to z through descriptor p (CHx[DESp]) using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]->CHx[DES1] ->....->CHx[DESp]->CHx[Data(p + 1)] -> CHz[Data1]->CHz[DES1] ->

The user must continue the linking until channels CHx and CHz complete their super-block transfers; otherwise, the channels remain enabled.

NOTE: In channel linking, the head of a chain can be in fast mode or nonfast mode. All channels that are not in the head of the chain can be in nonfast mode only. In self-linking, the channel cannot be in fast mode.

NOTE: If channel CHx links to CHz in the middle of the superblock transfer (remember link bit can be set through Type-1 descriptor load), CHx will get disabled after the corresponding data load and enables the channel CHz.

11.5 SDMA Basic Programming Model

11.5.1 Setup Configuration

After a hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the `DMA4_GCR` register, and any required interrupts must be enabled through the `DMA4_IRQENABLE_Lj` registers and the logical channel `DMA4_CICRi` registers.

Software clears the [DMA4_CSRI](#) register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

11.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

- Configure the transfer parameters in the logical DMA channel registers:
 - DMA4_CSDPi:
 - Transfer ES (8 bits, 16 bits, or 32 bits) and DMA register bits DMA4_CSDPi[1:0]
 - Read and write port access types (single/burst), DMA register bits DMA4_CSDPi[8:7] and DMA4_CSDPi[15:14]
 - Source and destination endianism, DMA register bits DMA4_CSDPi[21] and DMA4_CSDPi[19]
 - Write mode (posted or nonposted) and DMA register bits DMA4_CSDPi[17:16]
 - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA register bits DMA4_CSDPi[6] and DMA4_CSDPi[13]
 - DMA4_CENi: EN
 - DMA4_CFNi: FN per transfer block
 - DMA4_CSSAi and DMA4_CDSEi: Source and destination start address (aligned with transfer ES)
 - DMA4_CCRi:
 - Read and write port addressing modes, DMA register bits DMA4_CCRi[13:12] and DMA4_CCRi[15:14]
 - Priority bit for both read and write ports, DMA register bits DMA4_CCRi[6] and DMA4_CCRi[26]
 - DMA request number (set to 0 for a software-triggered transfer) and DMA register bits DMA4_CCRi[4:0] = 0 and DMA4_CCRi[20:19] = 0
 - DMA4_CSEi, DMA4_CSFi, DMA4_CDEi, and DMA4_CDFi: Source and destination element and frame indexes (depending on addressing mode)
 - Start the transfer through the enable bit in the channel DMA4_CCRi register and DMA register bit DMA4_CCRi[7]

The example below perform a DMA transfer on channel 10 of a 240*160 picture from RAM to RAM (0x80C00000 to 0x80F00000) :

```

UWORD32 RegVal = 0; DMA4_t *DMA4; DMA4 = (DMA4_t *)malloc(sizeof(DMA4_t)); /* Init. parameters
*/ DMA4->DataType = 0x2; // DMA4_CSDPi[1:0] DMA4->ReadPortAccessType = 0; // DMA4_CSDPi[8:7] DMA4-
>WritePortAccessType = 0; // DMA4_CSDPi[15:14] DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21] DMA4-
>DestinationEndianism = 0; // DMA4_CSDPi[19] DMA4->WriteMode = 0; // DMA4_CSDPi[17:16] DMA4-
>SourcePacked = 0; // DMA4_CSDPi[6] DMA4->DestinationPacked = 0; // DMA4_CSDPi[13] DMA4-
>NumberOfElementPerFrame = 240; // DMA4_CENI DMA4->NumberOfFramePerTransferBlock = 160; //
DMA4_CFNI DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAI DMA4->DestinationStartAddress =
0x80F00000; // DMA4_CDSAi DMA4->SourceElementIndex = 1; // DMA4_CSEi DMA4->SourceFrameIndex = 1;
// DMA4_CSFi DMA4->DestinationElementIndex = 1; // DMA4_CDEi DMA4->DestinationFrameIndex = 1; //
DMA4_CDFI DMA4->ReadPortAccessMode = 1; // DMA4_CCRI[13:12] DMA4->WritePortAccessMode = 1; //
DMA4_CCRI[15:14] DMA4->ReadPriority = 0; // DMA4_CCRI[6] DMA4->WritePriority = 0; //
DMA4_CCRI[23] DMA4->ReadRequestNumber = 0; // DMA4_CCRI[4:0] DMA4->WriteRequestNumber = 0; //
DMA4_CCRI[20:19] /* 1) Configure the transfer parametres in the logical DMA registers */ /*-----*

the DMA transfer by Setting the enable bit CCR[7]=1 */ /*-----*
-----*/ //write enable bit DMA4_CCR_CH10 |= 1 << 7; /* start */

```

11.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the [DMA4_CDACi](#) register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization [DMA4_CCRI](#)[5] FS bit and the block synchronization [DMA4_CCRI](#)[18] BS bit register must be programmed. For all the following synchronized transfers (element, packet, frame or block synchronized transfers) User must set first : [DMA4_CCRI](#)[24] SEL_SRC_DST_SYNC to 1 when the source triggers on the DMA request and [DMA4_CCRI](#)[24] SEL_SRC_DST_SYNC to 0 when the Destination triggers on the DMA request. Note: User must take care when setting the [DMA4_CCRI](#)[23] PREFETCH bit it is in conjunction with [DMA4_CCRI](#)[24] SEL_SRC_DST_SYNC bit .

- To configure an LCh to transfer one element per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRI](#)[20:19] SYNCHRO_CONTROL_UPPER and [DMA4_CCRI](#)[4:0] SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi](#)[1:0] DATA_TYPE bit field.
 3. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi](#)[8:7] SRC_BURST_EN bit field.
 4. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi](#)[15:14] DST_BURST_EN bit field.
 5. Set the Read Port addressing mode in the [DMA4_CCRI](#)[13:12] SRC_AMODE bit field.
 6. Set the Write Port addressing mode in the [DMA4_CCRI](#)[15:14] DST_AMODE bit field.
 7. Set the Read start address in the [DMA4_CSSA](#)[31:0] SRC_START_ADRS bit field.
 8. Set the Write start address in the [DMA4_CDSA](#)[31:0] DST_START_ADRS bit field.
 9. Set both FS and BS to 0 in [DMA4_CCRI](#)[5] FS and [DMA4_CCRI](#)[18] BS.
 10. Set to 1 the channel enable bit [DMA4_CCRI](#)[7] EN bit.
- To configure an LCh to transfer one frame per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRI](#)[20:19] SYNCHRO_CONTROL_UPPER and [DMA4_CCRI](#)[4:0] SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi](#)[1:0] DATA_TYPE bit field.

3. Set the number of element per frame in the [DMA4_CENi\[23:0\]](#) CHANNEL_ELMNT_NBR bit field.
4. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN bit field.
5. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi\[15:14\]](#) DST_BURST_EN bit field.
6. Set the Read Port addressing mode in the [DMA4_CCRI\[13:12\]](#) SRC_AMODE bit field.
7. Set the Write Port addressing mode in the [DMA4_CCRI\[15:14\]](#) DST_AMODE bit field.
8. Set the Read start address in the [DMA4_CSSAi\[31:0\]](#) SRC_START_ADRS bit field.
9. Set the Write start address in the [DMA4_CDSAi\[31:0\]](#) DST_START_ADRS bit field.
10. Set FS to 1 and BS to 0 respectively in [DMA4_CCRI\[5\]](#) FS and [DMA4_CCRI\[18\]](#) BS.
11. Set to 1 the channel enable bit [DMA4_CCRI\[7\]](#) EN bit.
 - To configure an LCh to transfer one block per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRI\[20:19\]](#) SYNCHRO_CONTROL_UPPER and [DMA4_CCRI\[4:0\]](#) SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi\[1:0\]](#) DATA_TYPE bit field.
 3. Set the number of element per frame in the [DMA4_CENi\[23:0\]](#) CHANNEL_ELMNT_NBR bit field.
 4. Set in the [DMA4_CFNi\[15:0\]](#) CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH is disabled.
 5. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN bit field.
 6. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi\[15:14\]](#) DST_BURST_EN bit field.
 7. Set the Read Port addressing mode in the [DMA4_CCRI\[13:12\]](#) SRC_AMODE bit field.
 8. Set the Write Port addressing mode in the [DMA4_CCRI\[15:14\]](#) DST_AMODE bit field.
 9. Set the Read start address in the [DMA4_CSSAi\[31:0\]](#) SRC_START_ADRS bit field.
 10. Set the Write start address in the [DMA4_CDSAi\[31:0\]](#) DST_START_ADRS bit field.
 11. Set FS to 0 and BS to 1 respectively in [DMA4_CCRI\[5\]](#) FS and [DMA4_CCRI\[18\]](#) BS.
 12. Set to 1 the channel enable bit [DMA4_CCRI\[7\]](#) EN bit.
 - To configure an LCh to transfer one packet per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRI\[20:19\]](#) SYNCHRO_CONTROL_UPPER and [DMA4_CCRI\[4:0\]](#) SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi\[1:0\]](#) DATA_TYPE bit field.
 3. Set the number of elements per packet to transfer: If the packet requestor is in the source, set DMA4_CCR [24] SEL_SRC_DST_SYNC to 1 and set the packet element number in the [DMA4_CSFIi](#) register and set the addressing mode of source to constant addressing in [DMA4_CCRI\[13:12\]](#) SRC_AMODE bit field; else, if the packet requestor is in the destination, set the [DMA4_CCRI\[24\]](#) SEL_SRC_DST_SYNC to 0 and set the packet element number in the [DMA4_CDFIi](#) register and set the addressing mode of destination to constant addressing in [DMA4_CCRI\[15:14\]](#) DST_AMODE bit field.
 4. Set the number of element per frame in the [DMA4_CENi\[23:0\]](#) CHANNEL_ELMNT_NBR bit field.
 5. Set in the [DMA4_CFNI\[15:0\]](#) CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH is disabled.
 6. Set the element number in the packet in the [DMA4_CSFIi\[15:0\]](#) PKT_ELNT_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of elements in the packet is set in the [DMA4_CDFIi\[15:0\]](#) PKT_ELNT_NBR if constant addressing mode is used in the destination side.
 7. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN bit field.

8. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi](#)[15:14] DST_BURST_EN bit field.
9. Set the Read start address in the [DMA4_CSSAi](#)[31:0] SRC_START_ADRS bit field.
10. Set the Write start address in the [DMA4_CDSAi](#)[31:0] DST_START_ADRS bit field.
11. Set FS to 1 and BS to 1 respectively in [DMA4_CCRi](#)[5] FS and [DMA4_CCRi](#)[18] BS.
12. Set to 1 the channel enable bit [DMA4_CCRi](#)[7] EN bit.

NOTE: It is possible to stop a transfer by disabling the channel. This is done by resetting the ENABLE bit in the [DMA4_CCRi](#) register.

11.5.4 Synchronized Transfer Monitoring Using CDAC

The [DMA4_CDACi](#) register is writable and non-initialized during reset (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in [DMA4_CDACi](#)
2. Enable the channel.
3. If timeout occurs, read [DMA4_CDACi](#)
4. If [DMA4_CDACi](#) != 0 (it is the value configured in [DMA4_CDACi](#)):

This indicates that the corresponding transfer has started. User can then rely on [DMA4_CCENi](#) and [DMA4_CCFNi](#) element and frame counters.

Else, if [DMA4_CDACi](#) = 0 (it is the value configured in the [DMA4_CDACi](#)):

This indicates that the corresponding transfer did not start.

11.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only, not the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread on the synchronized target side at least.

Even for multiple concurrent channels, thread reservation guarantees that as soon as an HW DMA request comes in, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider these six concurrent channels:

- Channels 0/1/2/3 are dedicated to memory-memory transfer: they are software triggered and not synchronized.
 - Channel 4 is dedicated to memory→peripheral transfer, hardware triggered, and synchronized on the write side.
 - Channel 5 is dedicated to peripheral→memory transfer, hardware triggered, and synchronized on the read side.
1. Allow thread reservation for priority channel 4 and channel 5:
Reserve one thread (Read ThreadID 0) on the read port: Set [DMA4_GCR](#)[13:12] = 0x1.
Reserve one thread (Write ThreadID 0) on the write port: Set [DMA4_GCR](#)[13:12] = 0x1.
 2. Specify channel priority:
Channel 4 is a write high priority channel: Set [DMA4_CCRi](#)[26] = 1.
Channel 5 is a read high priority channel: Set [DMA4_CCRi](#)[6] = 1.

11.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers above.
2. For each channel in the chain, configure the [DMA4_CLNK_CTRLi](#) register as follows:

- Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in DMA register bits [DMA4_CLNK_CTRLi\[4:0\]](#).
 - Include the logical channel to the chain and enable link by setting the DMA register bit [DMA4_CLNK_CTRLi\[15\]](#).
 - For a non-looping chain, the last logical channel in the chain must have the DMA register bit [DMA4_CLNK_CTRLi\[15\]](#) set to 0 to indicate the end of the chain.
3. Enable the transfer via the enable bit in the first logical channel DMA register bit [DMA4_CCRi\[7\]](#). All other channels in the chain must be configured as disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the [DMA4_CLNK_CTRLi\[15\]](#) ENABLE_LNK bit (by setting it to 0x0), of the final channel transfer.

In the RAM to RAM copy example, to copy in loop it's possible to link channel 10 on itself. The following line can be added in the channel configuration :

```
/* g) Set link for loop */ DMA4_CLINK_CTRL_CH10 = 0x0000800A;
```

11.5.7 90-Degree Clockwise Image Rotation

The 90-degree clockwise image rotation example described in [Section 11.4.3, Addressing Modes](#), can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:

- [DMA4_CSDPi](#):
 - Transfer ES = 32-bit (32 bpp), DMA register bits [DMA4_CSDPi\[1:0\]](#)
 - Read and write port access types = maximum burst size supported by memory device, DMA register bits [DMA4_CSDPi\[8:7\]](#) and [DMA4_CSDPi\[15:14\]](#)
 - Source and destination endianism, DMA register bits [DMA4_CSDPi\[21\]](#) and [DMA4_CSDPi\[19\]](#)
 - Write mode = posted with last element nonposted, DMA register bits [DMA4_CSDPi\[17:16\]](#)
 - Source and destination packed = Yes (although destination writes will not benefit because EI>1), DMA register bits [DMA4_CSDPi\[6\]](#) and [DMA4_CSDPi\[13\]](#)
- [DMA4_CENi](#): EN = 240
- [DMA4_CFNi](#): FN per transfer block = 160
- [DMA4_CSSAi](#): Source start address = 0x100000
- [DMA4_CDSAi](#): destination start address = 0x20013E
- [DMA4_CCRi](#):
 - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, DMA register bits [DMA4_CCRi\[13:12\]](#) and [DMA4_CCRi\[15:14\]](#)
 - Low or high priority, DMA register bit [DMA4_CCRi\[6\]](#)
 - DMA request number = 0 (for software-triggered transfer), DMA register bits [DMA4_CCRi\[4:0\]](#) and [DMA4_CCRi\[20:19\]](#)
- [DMA4_CSEi](#): Source EI = 1
- [DMA4_CSFi](#): Source frame index = 1
- [DMA4_CDEi](#): destination EI = 637
- [DMA4_CDFi](#): destination frame index = -152967

2. Start the transfer via the enable bit in the channel [DMA4_CCRi](#) register.

Below are the parameters to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code as in [Section 11.5.2](#):

```
/* Init. parameters */ DMA4->DataType = 0x2; // DMA4_CSDPi[1:0] DMA4->ReadPortAccessType = 0x3;
// DMA4_CSDPi[8:7] DMA4->WritePortAccessType = 0x3; // DMA4_CSDPi[15:14] DMA4->SourceEndiansim =
0; // DMA4_CSDPi[21] DMA4->DestinationEndianism = 0; // DMA4_CSDPi[19] DMA4->WriteMode = 0x2; //
DMA4_CSDPi[17:16] DMA4->SourcePacked = 0x1; // DMA4_CSDPi[6] DMA4->DestinationPacked = 0x1; //
DMA4_CSDPi[13] DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi DMA4-
>NumberOfFramePerTransferBlock = 160; // DMA4_CFNi DMA4->SourceStartAddress = 0x80C00000; //
DMA4_CSSAi DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSEAi DMA4->SourceElementIndex =
1; // DMA4_CSEi DMA4->SourceFrameIndex = 1; // DMA4_CSFi DMA4->DestinationElementIndex = 637; //
DMA4_CDEi DMA4->DestinationFrameIndex = -152967; // DMA4_CDFi DMA4->ReadPortAccessMode = 0x3; //
DMA4_CCRi[13:12] DMA4->WritePortAccessMode = 0x3; // DMA4_CCRi[15:14] DMA4->ReadPriority = 0; //
DMA4_CCRi[6] DMA4->WritePriority = 0; // DMA4_CCRi[23] DMA4->ReadRequestNumber = 0; //
DMA4_CCRi[4:0] DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]
```

11.5.8 Graphic Operations

- Transparent copy:
 - 1. Set the [DMA4_CCRI\[17\]](#) Transparent_Copy_Enable bit field to 1.
 - 2. Set the [DMA4_CCRI\[16\]](#) Constant_Fill_Enable bit field to 0.
 - 3. Set the value of key the color in the [DMA4_COLORi\[15:0\]](#) color_key bit field.

To perform this graphic operation, the following lines can be added to the example of [Section 11.5.2](#)

```
DMA4_CCR_CH10 &= ~(0x1 << 16); DMA4_CCR_CH10 |= 0x1 << 17; DMA4_COLOR_CH10 = 0x00000003;
```

- Solid Color fill:
 - 1. Set the [DMA4_CCRI\[16\]](#) Constant_Fill_Enable bit field to 1.
 - 2. Set the [DMA4_CCRI\[17\]](#) Transparent_Copy_Enable bit field to 0.
 - 3. Set the value of key the color in the [DMA4_COLORi\[15:0\]](#) solid_color bit field.

To perform this graphic operation, the following lines can be added to the example of [Section 11.5.2](#)

```
DMA4_CCR_CH10 &= ~(0x1 << 17); DMA4_CCR_CH10 |= 0x1 << 16; DMA4_COLOR_CH10 = 0x00000003;
```

11.6 SDMA Register Manual

11.6.1 SDMA Instance Summary

[Table 11-14](#) summarizes the SDMA instance.

Table 11-14. SDMA Instance Summary

Module Name	Base Address	Size
SDMA	0x4805 6000	4K bytes

11.6.2 SDMA Register Summary

[Table 11-15](#) summarizes the SDMA registers.

Index i represents the logical channel number ($i = 0$ to 31). The offset address for some registers is calculated from channel c number. For example, register DMA4_CCR10 (channel 10) has an offset address of $10 * 0x60 = 0x3C0$, and so a physical address of $0x4805\ 6080 + 0x3C0 = 0x4805\ 6440$.

Index j represents the interrupt line number ($j = 0$ to 3). The offset address for some registers is calculated from channel number. For example, register DMA4 IRQSTATUS_L3 (line 3) has an offset address of $3 * 0x4 = 0xC$, and so a physical address of $0x4805\ 6008 + 0xC = 0x4805\ 6014$.

Table 11-15. SDMA Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	SDMA Physical Address
DMA4_REVISION	R	32	0x0000 0000	0x4805 6000

11.6.3 SDMA Register Description

NOTE: Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

The shadow registers are used to read run time registers such as CCEN, CCFN, CDAC, or CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers may change. This shadow register is used to hold the whole value to allow the next access to recover the remaining 24 bits or 16 bits.

For non-32-bit transactions, start reading or writing from the LSByte first to enable the register update. There is no issue for 32-bit read-write transactions.

Table 11-16. DMA4_REVISION

Address Offset	0x0000 0000																Instance	SDMA

Table 11-36. DMA4_CCRi

Address Offset	0x0000 0080 + (i* 0x60)	Index	i = 0 to 31
Physical Address	0x4805 6080 + (i* 0x60)	Instance	SDMA
Description	Channel Control Register		
Type	RW		

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Reserved. Write 0s for future compatibility. Read returns 0.	RW	0x00
26	WRITE_PRIORITY	Channel priority on the Write side 0x0: Channel has low priority on the Write side during the arbitration process 0x1: Channel has high priority on Write sided during the arbitration process	RW	0x0
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: buffering is enable across element/packet when source is synchronized to element, packet, frame or blocks 0x1: buffering is disabled across element/packet when source is synchronized to element, packet, frame or blocks	RW	0x-
24	SEL_SRC_DST_SYNC	Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register	RW	0x-
23	PREFETCH	Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronized. It is SW user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported	RW	0x0
22	SUPERVISOR	Enables the supervisor mode 0x0: Supervisor mode is disabled 0x1: Supervisor mode is enabled	RW	0x0
21	RESERVED	Reserved for non-GP devices	RW	0x0

Bits	Field Name	Description	Type	Reset
20:19	SYNCHRO_CONTROL_UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel DMA4_CCR[4:0]) Used in conjunction, as two msb, with the five bits of the synchro channel bit field.	RW	0x0
18	BS	Block synchronization This bit used with the fs to see how the DMA request is serviced in a synchronized transfer	RW	0x-
17	TRANSPARENT_COPY_ENABLE	Transparent copy enable 0x0: Transparent copy mode is disabled 0x1: Transparent copy mode is enabled	RW	0x-
16	CONST_FILL_ENABLE	Constant fill enable 0x0: Constant fill mode is disabled 0x1: Constant fill mode is enabled	RW	0x0
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0x-
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0x-
11	RESERVED	Reserved. Write 0s for future compatibility. Read returns 0.	RW	0x0
10	WR_ACTIVE	Indicates if the channel write context is active or not 0x0: Channel is not active on the write port 0x1: Channel is active on the write port	R	0x0
9	RD_ACTIVE	Indicates if the channel read context is active or not 0x0: Channel is not active on the read port 0x1: Channel is currently active on the read port	R	0x0
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions	RW	0x0
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled 0x1: The logical channel is enabled	RW	0x0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the Read side during the arbitration process 0x1: Channel has high priority on read sided during the arbitration process	RW	0x0

Bits	Field Name	Description	Type	Reset
5	FS	<p>Frame synchronization</p> <p>This bit used with the BS to see how the DMA request is serviced in a synchronized transfer</p> <p>FS=0 and BS=0: An element is transferred once a DMA request is made.</p> <p>FS=0 and BS=1: An entire block is transferred once a DMA request is made.</p> <p>FS=1 and BS=0: An entire frame is transferred once a DMA request is made.</p> <p>FS=1 and BS=1: A packet is transferred once a DMA request is made.</p> <p>All these different transfers can be interleaved on the port with other DMA requests.</p>	RW	0x-
4:0	SYNCHRO_CONTROL	<p>Channel synchronization control</p> <p>This bit used with the second_level_synchro_control_upper (as two msb)</p> <p>0000000 : Is reserved for non synchronized LCH transfer</p> <p>xxxxxx (from 1 to 127) There are 127 possible DMA request to assign to any LCH.</p> <p>Note: The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, SYNCHRO_CONTROL bits (formed by DMA4_CCRi[20:19] and DMA4_CCRi[4:0]) must be set to 0x2 (DMA request number + 1).</p>	RW	0x00

Interrupt Controller

This chapter gives an overview of the interrupt controllers (INTCs) and describes in detail the MPU subsystem interrupt controller (MPU_INTC) module.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

12.6 Interrupt Controller Register Manual	2433

12.1 Interrupt Controller Overview

The device provides three interrupt controller (INTC) modules:

- **MPU subsystem INTC (INTCPS):** This module handles all MPU-related events, using Priority Threshold. It communicates with the public ARM Cortex-A8 processor using a private local interconnect, and runs at half the speed of the processor.
- **IVA2.2 subsystem INTC:** This module is a specific combination of WUGEN (wake-up generator) and the C64x+ DSP interrupt controller (IC). It is used in the device, but is not described in detail in this chapter. For detailed information about this INTC, see [Chapter 5, IVA2.2 Subsystem](#).
- **Modem INTC:** This module is an L4-mapped INTC that allows the regrouping of all the interrupts sent to the modem subsystem in stacked mode. It is seen as a level 2 INTC by the MPU and IVA2.2 subsystems. This modem INTC is integrated in the stand-alone device, but it is used only with the stacked modem. Therefore, it is not described in detail in this TRM, which focuses on the stand-alone device.

[Figure 12-1](#) shows the internal interrupt scheme with optional modem INTC (not used in the stand-alone configuration).

Figure 12-1. Interrupt Controllers Highlight

intc-001

12.2 Interrupt Controller Environment

The INTC can handle two types of interrupts originating from an external device:

- sys_nirq interrupt inputs:

The MPU INTC and modem INTC handle external interrupts through a dedicated sys_nirq interrupt line that connects the two INTC modules with a power IC, respectively. An interrupt can generate a system wake-up event.

If the system is idle and the external interrupt is masked, the interrupt cannot wake up the system. Like other interrupt lines, the external interrupt is active at low level and is acknowledged by the software according to the common programming model.

NOTE: If the CORE power domain is in retention (CSWR or OSWR) or off mode, the interrupt requests (internal or external), the MPU INTC, and the modem INTC (in the CORE domain) have no effect. The CORE power domain does not wake up, and the interrupt is not signaled to the MPU/modem.

- GPIO interrupt inputs:

External devices can also use GPIO modules to generate interrupts to the MPU and the modem. There are six dedicated interrupt lines to the MPU INTC and four dedicated interrupt inputs to the modem INTC. One interrupt line is associated with each GPIO module. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs. For more information about GPIO features, see [Chapter 25, General-Purpose Interface](#).

Figure 12-2 shows the relationship between the device and external interrupts.

Figure 12-2. Interrupts From External Devices

NOTE: The modem INTC cannot use GPIO5 and GPIO6 as interrupt sources.

The features specific to INTCPS are:

- Up to 96 level-sensitive interrupt inputs
- Individual priority (up to 64) for each interrupt input
- Interrupt lines connected to internal module interrupts
- One incoming interrupt line from an external device

12.3 MPU Subsystem INTCPS Integration

The INTCPS module is the interface between incoming interrupts and the two interrupt inputs of the MPU. It can handle up to 96 request inputs that can be configured as MPU FIQ or IRQ interrupt requests.

[Figure 12-3](#) shows the integration of the INTCPS in the MPU subsystem.

Figure 12-3. MPU Subsystem INTCPS Integration

The MPU subsystem INTCPS is directly connected to the MPU by an MPU peripheral port. Consequently, the MPU subsystem INTCPS is accessible and visible only by the MPU.

12.3.1 Clocking, Reset, and Power Management Scheme

12.3.1.1 MPU Subsystem INTC Clocks

The MPU subsystem INTCPS runs at half the rate of the MPU functional clock (see [Chapter 4, MPU Subsystem](#)).

The interface clock used for register access runs at the rate of the interconnect bus clock (equal to the rate of the MPU interface clock; see [Chapter 3, Power, Reset, and Clock Management](#)).

The synchronizer clock allows external asynchronous interrupts to be resynchronized before they are masked.

[Table 12-1](#) lists the MPU subsystem INTC clock rates.

Table 12-1. MPU Subsystem INTC Clock Rates

Clock	Frequency	Name	Comments
Functional	ARM_FCLK	MPU_INTC_FCLK	Source is the MPU DLL.
Interface	ARM_FCLK	MPU_INTC_ICLK	Source is the PRCM module.
Synchronizer	MPU_INTC_FCLK	Synchronizer clock (module internal clock)	Source is the MPU_INTC_FCLK.

12.3.1.2 Hardware and Software Reset

[Table 12-2](#) lists the MPU subsystem INTC resets.

Table 12-2. Hardware and Software Reset

Type	Name	Source	Activation	Domain
Hardware	CORE_RST	PRCM	Active low	CORE
Software	SOFTRESET	MPU_INTC. INTCPS_SYSCONFIG[1] SOFTRESET bit	Active at 1	MPU INTC internal

12.3.1.3 Power Management

The MPU subsystem INTC belongs to the CORE power domain. As part of CORE power domain, it is sensitive to a CORE_RST issued by the PRCM. For more information about the CORE power domain implementation and CORE_RST signal, see [Chapter 3, Power, Reset, and Clock Management](#).

The MPU INTC clocks come from the MPU DPLL. For more information about these clocks control, see [Chapter 4, MPU Subsystem](#).

12.3.2 Interrupt Request Lines

[Table 12-3](#) lists the incoming and outgoing interrupt lines of the INTCPS.

Table 12-3. Interrupt Lines Incoming and Outgoing

Type	Number	Name	Mapping	Comments
Interrupt request inputs	Up to 96	M_IRQ_[95:0]	See Table 12-4	Inputs to INTCPS module, source from various modules.
Interrupt request outputs	2	MPU_INTC_FIQ	MPU_INTC_FIQ	Outgoing to MPU Fast Interrupt
		MPU_INTC IRQ	MPU_INTC IRQ	Outgoing to MPU Normal Interrupt

NOTE: Interrupt request signals are active at low level.

CAUTION

A single interrupt source can be physically mapped to multiple INTCs (MPU subsystem, IVA2.2 subsystem, and modem). With multiple-mapped interrupts, it is strongly recommended each interrupt source be unmapped in only one INTC at a time.

[Table 12-4](#) lists interrupt mappings to the MPU subsystem.

Table 12-4. Interrupt Mapping to the MPU Subsystem⁽¹⁾

12.4 Interrupt Controller Functional Description

The main features of the INTCPS are:

- Individual priority (up to 64 levels) for each interrupt input
- Ability for each interrupt to be steered to either FIQ or IRQ
- Independent priority sorting for FIQ and IRQ; FIQ sorting is processed concurrently with IRQ sorting.
- Priority masking: Interrupts can be masked based on the priority threshold register.
- Atomic bit set and clear capability for interrupt mask and software interrupt registers
- Power-management and wake-up support
- Auto-idle power-saving support

The INTCPS processes incoming interrupts by masking and priority sorting, then it generates the interrupt requests to the MPU.

[Figure 12-4](#) shows the top-level view of the interrupt processing.

Figure 12-4. Top-Level Block Diagram

intc-004

12.4.1 Interrupt Processing

12.4.1.1 Input Selection

The INTCPS supports only level-sensitive incoming interrupt detection. A peripheral asserting an interrupt maintains it until software has handled the interrupt and instructed the peripheral to deassert the interrupt.

A software interrupt is generated if the corresponding bit in the MPU_INTC.[INTCPS_ISR_SETn](#) register is set (register bank number: n = [0,2] for the MPU subsystem INTCPS, 96 incoming interrupt lines are supported). The software interrupt clears when the corresponding bit in the MPU_INTC.[INTCPS_ISR_CLEARn](#) register is written. Typical use of this feature is software debugging.

12.4.1.2 Masking

12.4.1.2.1 Individual Masking

Detection of interrupts on each incoming interrupt line can be enabled or disabled independently by the MPU_INTC.[INTCPS_MIRn](#) interrupt mask register. In response to an unmasked incoming interrupt, the INTCPS can generate one of two types of interrupt requests to the processor:

- IRQ: low-priority interrupt request
- FIQ: fast interrupt request

The type of interrupt request is determined by the MPU_INTC.[INTCPS_ILRm\[0\]](#) FIQNIRQ bit (m= [0,95]).

The current incoming interrupt status before masking is readable from the MPU_INTC.[INTCPS_ITRn](#) register. After masking and IRQ/FIQ selection, and before priority sorting is done, the interrupt status is readable from the MPU_INTC.[INTCPS_PENDING_IRQn](#) and MPU_INTC.[INTCPS_PENDING_FIQn](#) registers.

12.4.1.2.2 Priority Masking

To enable faster processing of high-priority interrupts, a programmable priority masking threshold is provided (the MPU_INTC.[INTCPS_THRESHOLD\[7:0\]](#) PRIORITYTHRESHOLD field). This priority threshold allows preemption by higher priority interrupts; all interrupts of lower or equal priority than the threshold are masked. However, priority 0 can never be masked by this threshold; a priority threshold of 0 is treated the same way as priority 1.

PRIORITY and PRIORITYTHRESHOLD fields values can be set between 0x0 and 0x3F; 0x0 is the highest priority and 0x3F is the lowest priority.

When priority masking is not necessary, a priority threshold value of 0xFF disables the priority threshold mechanism. This value is also the reset default for backward compatibility with previous versions of the INTCPS.

12.4.1.3 Priority Sorting

A priority level (0 being the highest) is assigned to each incoming interrupt line. Both the priority level and the interrupt request type are configured by the MPU_INTC.[INTCPS_ILRm](#) register. If more than one incoming interrupt with the same priority level and interrupt request type occur simultaneously, the highest-numbered interrupt is serviced first.

When one or more unmasked incoming interrupts are detected, the INTCPS separates between IRQ and FIQ using the corresponding MPU_INTC.[INTCPS_ILRm\[0\]](#) FIQNIRQ bit. The result is placed in [INTCPS_PENDING_IRQn](#) or [INTCPS_PENDING_FIQn](#).

If no other interrupts are currently being processed, INTCPS asserts IRQ/FIQ and starts the priority computation. Priority sorting for IRQ and FIQ can execute in parallel.

Each IRQ/FIQ priority sorter determines the highest priority interrupt number. Each priority number is placed in the corresponding MPU_INTC.[INTCPS_SIR_IRQ\[6:0\]](#) ACTIVEIRQ field or MPU_INTC.[INTCPS_SIR_FIQ\[6:0\]](#) ACTIVEFIQ field. The value is preserved until the corresponding MPU_INTC.[INTCPS_CONTROL](#) NEWIRQAGR or NEWFIQAGR bit is set.

Once the interrupting peripheral device has been serviced and the incoming interrupt deasserted, the user must write to the appropriate NEWIRQAGR or NEWFIQAGR bit to indicate to the INTCPS the interrupt has been handled. If there are any pending unmasked incoming interrupts for this interrupt request type, the INTCPS restarts the appropriate priority sorter; otherwise, the IRQ or FIQ interrupt line is deasserted.

12.4.2 Register Protection

If the MPU_INTC.[INTCPS_PROTECTION](#)[0] PROTECTION bit is set, access to the INTCPS registers is restricted to the supervisor mode. Access to the MPU_INTC.[INTCPS_PROTECTION](#) register is always restricted to privileged mode.

12.4.3 Module Power Saving

The INTCPS provides an auto-idle function in its three clock domains:

- Interface clock
- Functional clock
- Synchronizer clock

The interface clock auto-idle power-saving mode is enabled if the MPU_INTC.[INTCPS_SYSConfig](#)[0] AUTOIDLE bit is set to 1. When this mode is enabled and there is no activity on the bus interface, the interface clock is disabled internally to the module, thus reducing power consumption. When there is new activity on the bus interface, the interface clock restarts without any latency penalty. After reset, this mode is disabled, by default.

The functional clock auto-idle power-saving mode is enabled if the MPU_INTC.[INTCPS_IDLE](#)[0] FUNCIDLE bit is set to 0. When this mode is enabled and there is no active interrupt (IRQ or FIQ interrupt being processed or generated) or no pending incoming interrupt, the functional clock is disabled internally to the module, thus reducing power consumption. When a new unmasked incoming interrupt is detected, the functional clock restarts and the INTCPS processes the interrupt. If this mode is disabled, the interrupt latency is reduced by one cycle. After reset, this mode is enabled, by default.

The synchronizer clock allows external asynchronous interrupts to be resynchronized before they are masked. The synchronizer input clock has an auto-idle power-saving mode enabled if the MPU_INTC.[INTCPS_IDLE](#)[1] TURBO bit is set to 1. If the auto-idle mode is enabled, the standby power is reduced, but the IRQ or FIQ interrupt latency increases from four to six functional clock cycles. This feature can be enabled dynamically according to the requirements of the device. After reset, this mode is disabled, by default.

To reduce power consumption of the modem INTC, which is not use in the stand-alone device, modem INTC clocks must be configured in auto-idle mode. Therefore, both the MPU_INTC.[INTCPS_SYSConfig](#)[0] AUTOIDLE and MPU_INTC.[INTCPS_IDLE](#)[1] TURBO bits must be set to 1 during initialization.

12.4.4 Interrupt Latency

The IRQ/FIQ interrupt generation takes four INTCPS functional clock cycles (plus or minus one cycle) if the MPU_INTC.[INTCPS_IDLE](#)[1] TURBO bit is set to 0. If the TURBO bit is set to 1, the interrupt generation takes six cycles, but power consumption is reduced while waiting for an interrupt.

These latencies can be reduced by one cycle by disabling functional clock auto-idle (MPU_INTC.[INTCPS_IDLE](#)[0] FUNCIDLE bit set to 1), but power consumption is increased, so the benefit is minimal. For information about power saving, see [Section 12.4.3](#).

To minimize interrupt latency when an unmasked interrupt occurs, the IRQ or FIQ interrupt is generated before priority sorting completion. The priority sorting takes 10 functional clock cycles, which is less than the minimum number of cycles required for the MPU to switch to the interrupt context after reception of the IRQ or FIQ event.

Any read of the MPU_INTC.[INTCPS_SIR_IRQ](#) or MPU_INTC.[INTCPS_SIR_FIQ](#) register during the priority sorting process stalls until priority sorting is complete and the relevant register is updated. However, the delay between the interrupt request being generated and the interrupt service routine being executed is such that priority sorting always completes before the MPU_INTC.[INTCPS_SIR_IRQ](#) or MPU_INTC.[INTCPS_SIR_FIQ](#) register is read.

12.5 Interrupt Controller Basic Programming Model

12.5.1 Initialization Sequence

1. Program the MPU_INTC.INTCPS_SYSCONFIG register: If necessary, enable the interface clock autogating by setting the AUTOIDLE bit.
2. Program the MPU_INTC.INTCPS_IDLE register: If necessary, disable functional clock autogating or enable synchronizer autogating by setting the FUNCIDLE bit or TURBO bit accordingly.
3. Program the MPU_INTC.INTCPS_ILRm register for each interrupt line: Assign a priority level and set the FIQNFIQ bit for an FIQ interrupt (by default, interrupts are mapped to IRQ and priority is 0x0 [highest]).
4. Program the MPU_INTC.INTCPS_MIRn register: Enable interrupts (by default, all interrupt lines are masked).

NOTE: To program the MPU_INTC.INTCPS_MIRn register, the MPU_INTC.INTCPS_MIR_SETn and MPU_INTC.INTCPS_MIR_CLEARn registers are provided to facilitate the masking, even if it is possible for backward-compatibility to write directly to the MPU_INTC.INTCPS_MIRn register.

12.5.2 MPU INTC Processing Sequence

After the MPU_INTC.INTCPS_MIRn and MPU_INTC.INTCPS_ILRm registers are configured to enable and assign priorities to incoming interrupts, the interrupt is processed as explained in the following subsections.

IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in **bold** characters in the text or the code below.

1. One or more unmasked incoming interrupts (**M_IRQ_n** signals) are received and IRQ or FIQ outputs (MPU_INTC_IRQ/**FIQ**) are not currently asserted.
2. If the MPU_INTC.INTCPS_ILRm[0] FIQNIRQ bit is set to 0, the MPU_INTC_IRQ output signal is generated. If the FIQNIRQ bit is set to 1, the MPU_INTC_FIQ output signal is generated.
3. The INTC performs the priority sorting and updates the MPU_INTC.INTCPS_SIR_IRQ[6:0] ACTIVEIRQ /**MPU_INTC.INTCPS_SIR_FIQ[6:0]** ACTIVEFIQ field with the current interrupt number.
4. During priority sorting, if the IRQ/**FIQ** is enabled at the host processor side, the host processor automatically saves the current context and executes the ISR as follows:

NOTE: The ARM host processor automatically performs the following actions in pseudo code.

```
LR = PC + 4          /* return link */  
SPSR = CPSR          /* Save CPSR before execution */  
CPSR[5] = 0          /* Execute in ARM state */  
CPSR[7] = 1          /* Disable IRQ */  
CPSR[8] = 1          /* Disable Imprecise Data Aborts */  
CPSR[9] = CP15_reg1_EEbit /* Endianness on exception entry */  
if interrupt == IRQ then  
    CPSR[4:0] = 0b10010 /* Enter IRQ mode */  
    if high vectors configured then  
        PC = 0xFFFFF0018 /* execute interrupt vector */  
    else  
        PC = 0x000000018 /* execute interrupt vector */  
else if interrupt == FIQ then  
    CPSR[4:0] = 0b10001 /* Enter FIQ mode */  
    CPSR[6] = 1          /* Disable FIQ */  
    if high vectors configured then  
        PC = 0xFFFFF001C /* execute interrupt vector */  
    else  
        PC = 0x00000001C /* execute interrupt vector */  
endif
```

5. The ISR saves the remaining context, identifies the interrupt source by reading the **ACTIVEIRQ/ACTIVEFIQ** field, and jumps to the relevant subroutine handler as follows:

CAUTION

The code in steps 5 and 7 is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
/* INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register address
INTCP_SIR_IRQ_ADDR/INTCP_SIR_FIQ_ADDR .word 0x48200040/0x48200044

/* ACTIVEIRQ bit field mask to get only the bit field
ACTIVEIRQ_MASK .equ 0x7F
_IRQ_ISR/_FIQ_ISR:

    /* Save the critical context
    STMF D SP!, {R0-R12, LR}           /* Save working registers and the Link register

    MRS R11, SPSR                      /* Save the SPSR into R11

    /* Get the number of the highest priority active IRQ/FIQ
    LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
    LDR R10, [R10]                      /* Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
    AND R10, R10, #ACTIVEIRQ_MASK       /* Apply the mask to get the active IRQ number

    /* Jump to relevant subroutine handler
    LDR PC, [PC, R10, lsl #2]          /* PC base address points this instruction + 8

    NOP                                /* To index the table by the PC

    /* Table of handler start addresses
    .word IRQ0handler ;For IRQ0 of BANK0
    .word IRQ1handler
    .word IRQ2handler
```

6. The subroutine handler executes code specific to the peripheral generating the interrupt by handling the event and deasserting the interrupt condition at the peripheral side.

```
/* IRQ0 subroutine
IRQ0handler:
    /* Save working registers
    STMF D SP!, {R0-R1}

    /* Now read-modify-write the peripheral module status register
    /* to de-assert the M_IRQ_0 interrupt signal

    /* De-Assert the peripheral interrupt

    MOV R0, #0x7                         /* Mask for 3 flags
    LDR R1, MODULE0_STATUS_REG_ADDR /* Get the address of the module Status Register
    STR R0, [R1]                          /* Clear the 3 flags

    /* Restore working registers      LDMFD SP!, {R0-R1}
    /* Jump to the end part of the ISR
    B IRQ_ISR_end/_FIQ_ISR_end
```

7. After the return of the subroutine, the ISR sets the **NEWIRQAGR/NEWFIQAGR** bit to enable the processing of subsequent pending IRQs/**FIQs** and to restore ARM context in the following code. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/**FIQs**, a Data Synchronization Barrier is used. This operation ensure that the IRQ/**FIQ** line is de-asserted before IRQ/**FIQ** enabling. After that, the INTc processes any other pending interrupts or deasserts the MPU_INTC_IRQ/MPU_INTC_FIQ signal if there is no interrupt.

```

/* INTCPS_CONTROL register address
INTCPS_CONTROL_ADDR .word 0x48200048;

NEWIRQAGR/NEWFIQAGR bit mask to set only the NEWIRQAGR/NEWFIQAGR bit
NEWIRQAGR_MASK/NEWFIQAGR_MASK .equ 0x01/0x02

IRQ_ISR_end/FIQ_ISR_end:

/* Allow new IRQs/FIQs at INTC side
/* The INTCPS_CONTROL register is a write only register so no need to write back others bits

    MOV R0, #NEWIRQAGR_MASK/NEWFIQAGR_MASK /* Get the NEWIRQAGR/NEWFIQAGR bit position
    LDR R1, INTCPS_CONTROL_ADDR
    STR R0, [R1] /* Write the NEWIRQAGR/NEWFIQAGR bit to allow
new IRQs/FIQs

    /* Data Synchronization Barrier
    MOV R0, #0
    MCR P15, #0, R0, C7, C10, #4

    /* restore critical context
    MSR SPSR, R11 /* Restore the SPSR from R11
    LDMFD SP!, {R0-R12, LR} /* Restore working registers and Link register

    /* Return after handling the interrupt
    SUBS PC, LR, #4

```

8. After the ISR return, the ARM automatically restores its context as follows:

```

CPSR = SPSR
PC = LR

```

[Figure 12-5](#) shows the IRQ/**FIQ** processing sequence from the originating device peripheral module to the main program interruption.

Figure 12-5. IRQ/FIQ Processing Sequence

NOTE: The differences between the IRQ and the FIQ sequence are highlighted in blue and bold characters.

The priority sorting mechanism is frozen during an interrupt processing sequence. If an interrupt condition occurs during this time, the interrupt is not lost. It is sorted when the NEWIRQAGR/**NEWFIQAGR** bit is set (priority sorting is reactivated).

12.5.3 MPU INTC Preemptive Processing Sequence

Preemptive interrupts, also called nested interrupts, can reduce the latencies for higher priority interrupts. A preemptive ISR can be suspended by a higher priority interrupt. Thus, the higher priority interrupt can be served immediately.

Nested interrupts must be used carefully to avoid using corrupted data. Programmers must save corruptible registers and enable IRQ or FIQ at ARM side.

IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in **bold** characters in the text or the code below.

To enable IRQ/**FIQ** preemption by higher priority IRQs/**FIQs**, programmers can follow this procedure to write the ISR:

At the beginning of an IRQ/**FIQ** ISR:

1. Save the ARM critical context registers.
2. Save the MPU_INTC.**INTCPS_THRESHOLD** PRIORITYTHRESHOLD field before modifying it.
3. Read the active interrupt priority in the MPU_INTC.**INTCPS_IRQ_PRIORITY** IRQPRIORITY / **MPU_INTC.INTCPS_FIQ_PRIORITY** FIQPRIORITY field and write it to the PRIORITYTHRESHOLD⁽¹⁾ field.
4. Read the active interrupt number in the MPU_INTC.**INTCPS_SIR_IRQ[6:0]** ACTIVEIRQ / **MPU_INTC.INTCPS_SIR_FIQ[6:0]** ACTIVEFIQ field to identify the interrupt source.
5. Write 1 to the appropriate MPU_INTC.**INTCPS_CONTROL** NEWIRQAGR and ⁽²⁾ NEWFIQAGR bit while an interrupt is still processing to allow only higher priority interrupts to preempt.
6. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/**FIQs**, a Data Synchronization Barrier is used. This operation ensure that the IRQ line is de-asserted before IRQ/**FIQ** enabling.
7. Enable IRQ/**FIQ** at ARM side.
8. Jump to the relevant subroutine handler.

The sample code below shows the previous steps:

CAUTION

The code below is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
/* bit field mask to get only the bit field ACTIVEPRIOR_MASK .equ 0x3F _IRQ_ISR: /* Step 1 : Save the critical context STMD SP!, {R0-R12, LR} /* Save working registers MRS R11, SPSR /* Save the SPSR into R11 /* Step 2 : Save the INTCPS_THRESHOLD register into R12 LDR R0, INTCPS_THRESHOLD_ADDR LDR R12, [R0] /* Step 3 : Get the priority of the highest priority active IRQ LDR R1, INTCPS_IRQ_PRIORITY_ADDR/INTCPS_FIQ_PRIORITY_ADDR LDR R1, [R1] /* Get the INTCPS_IRQ_PRIORITY/INTCPS_FIQ_PRIORITY register AND R1, R1, #ACTIVEPRIOR_MASK /* Apply the mask to get the priority of the IRQ STR R1, [R0] /* Write it to the INTCPS_THRESHOLD register /* Step 4 : Get the number of the highest priority active IRQ LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR LDR R10, [R10] /* Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register AND R10, R10, #ACTIVEIRQ_MASK /* Apply the mask to get the active IRQ number /* Step 5 : Allow new IRQs and FIQs at INTC side MOV R0, #0x1/0x3 /* Get the NEWIRQAGR and NEWFIQAGR bit position LDR R1, INTCPS_CONTROL_ADDR STR R0, [R1] /* Write the NEWIRQAGR and NEWFIQAGR bit position
```

⁽¹⁾ The priority-threshold mechanism is enabled automatically when writing a priority in the range of 0x00 to 0x3F while reading it from the IRQPRIORITY and FIQPRIORITY fields. Writing a value of 0xFF (reset default) disables the priority-threshold mechanism. Values between 0x3F and 0xFF must not be used.

When the hardware-priority threshold is in use, the priorities of interrupts selected as FIQ or IRQ become linked; otherwise, they are independent. When they are linked, all FIQ priorities must be set higher than all IRQ priorities to maintain the relative priority of FIQ over IRQ.

⁽²⁾ When handling FIQs using the priority-threshold mechanism, both NEWFIQAGR and NEWIRQAGR bits must be written at the same time to ensure that the new priority threshold is applied while an IRQ sort is in progress. This IRQ will not have been seen by the ARM, as it will have been masked on entry to the FIQ ISR. However, the source of the IRQ remains active and it is finally processed when the priority threshold falls to a priority sufficiently low to allow it to be processed. The precaution of writing to New FIQ Agreement is not required during an IRQ ISR, as FIQ sorting is not affected (providing all FIQ priorities are higher than all IRQ priorities).

```
NEWFIQAGR bit /* Step 6 : Data Synchronization Barrier MOV R0, #0 MCR P15, #0, R0, C7, C10, #4 */
Step 7 : Read-modify-write the CPSR to enable IRQs/FIQs at ARM side MRS R0, CPSR /* Read the
status register BIC R0, R0, #0x80/0x40 /* Clear the I/F bit MSR CPSR, R0 /* Write it back to
enable IRQs /* Step 8 : Jump to relevant subroutine handler LDR PC, [PC, R10, lsl #2] /* PC base
address points this instruction + 8 NOP /* To index the table by the PC /* Table of handler start
addresses .word IRQ0handler ;IRQ0 BANK0 .word IRQ1handler .word IRQ2handler
```

After the return of the relevant IRQ/FIQ subroutine handle :

1. Disable IRQs/FIQs at ARM side.
2. Restore the MPU_INTC.INTCPS_THRESHOLD PRIORITYTHRESHOLD field.
3. Restore the ARM critical context registers.

The sample code below shows the three previous steps:

CAUTION

The code below is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
IRQ_ISR_end: /* Step 1 : Read-modify-write the CPSR to disable IRQs/FIQs at ARM side MRS R0, CPSR
/* Read the CPSR ORR R0, R0, #0x80/0x40 /* Set the I/F bit MSR CPSR, R0 /* Write it back to
disable IRQs /* Step 2 : Restore the INTCPS_THRESHOLD register from R12 LDR R0,
INTCPS_THRESHOLD_ADDR STR R12, [R0] /* Step 3 : Restore critical context MSR SPSR, R11 /* Restore
the SPSR from R11 LDMFD SP!, {R0-R12, LR} /* Restore working registers and Link register /*
Return after handling the interrupt SUBS PC, LR, #4
```

[Figure 12-6](#) shows the nested IRQ/FIQ processing sequence from the originating device peripheral module to the main program interruption.

Figure 12-6. Nested IRQ/FIQ Sequence

intc-006

NOTE: The differences between the IRQ and the FIQ sequence are highlighted in blue and bold characters.

12.5.4 MPU INTC Spurious Interrupt Handling

The spurious flag indicates whether the result of the sorting (a window of 10 INTC functional clock cycles after the interrupt assertion) is invalid. The sorting is invalid if:

- The interrupt that triggered the sorting is no longer active during the sorting.
- A change in the mask has affected the result during the sorting time.

As a result, the values in the MPU_INTC.[INTCPS_MIRn](#), MPU_INTC.[INTCPS_ILRm](#), or MPU_INTC.[INTCPS_MIR_SETn](#) registers must not be changed while the corresponding interrupt is asserted. If these registers are changed within the 10-cycle window after the interrupt assertion, only the active interrupt input that triggered the sort can be masked before its turn in the sort. The resulting values of the following registers become invalid:

- MPU_INTC.[INTCPS_SIR_IRQ](#)
- MPU_INTC.[INTCPS_SIR_FIQ](#)
- MPU_INTC.[INTCPS_IRQ_PRIORITY](#)
- MPU_INTC.[INTCPS_FIQ_PRIORITY](#)

This condition is detected for both IRQ and FIQ, and the invalid status is flagged across the SPURIOUSIRQFLAG (see Note 1) and SPURIOUSFIQFLAG (see Note 2) bit fields in the SIR and PRIORITY registers. A 0 indicates valid and a 1 indicates invalid interrupt number and priority. The invalid indication can be tested in software as a false register value.

NOTE:

1. The MPU_INTC.[INTCPS_SIR_IRQ\[31:7\]](#) SPURIOUSIRQFLAG bit field is a copy of the MPU_INTC.[INTCPS_IRQ_PRIORITY\[31:7\]](#) SPURIOUSIRQFLAG bit field.
2. The MPU_INTC.[INTCPS_SIR_FIQ\[31:7\]](#) SPURIOUSFIQFLAG bit field is a copy of the MPU_INTC.[INTCPS_FIQ_PRIORITY\[31:7\]](#) SPURIOUSFIQFLAG bit field.

12.6 Interrupt Controller Register Manual

12.6.1 Instance Summary

[Table 12-5](#) lists the base address and address space for the INTC instances.

Table 12-5. INTC Instance Summary

Module Name	Base Address	Size
MPU INTC	0x4820 0000	4K bytes
Modem INTC	0x480C 7000	4K bytes

12.6.2 Register Summary

CAUTION

MPU INTC and Modem INTC registers are limited to 32-bit and 16-bit data accesses; 8-bit data access is not allowed and can corrupt the register content.

In [Section 12.6.3](#), each register from MPU_INTC.INTCPS_ITRn to MPU_INTC.INTCPS_PENDING_FIQn contains 32 bits, 1 bit for each interrupt (in ascending order: bit 0 of the MPU_INTC.INTCPS_ITR0 register applies to interrupt line 0; bit 0 of the MPU_INTC.INTCPS_ITR1 register applies to interrupt line 32).

System Control Module

This chapter describes the system control module (SCM).

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
13.1 SCM Overview	2448
13.2 SCM Environment	2449
13.3 SCM Integration	2450
13.4 SCM Functional Description	2454
13.5 SCM Programming Model	2543
13.6 SCM Register Manual	2559

13.1 SCM Overview

The system control module (SCM) allows software control of the various static modes supported by the device. The SCM is on the L4-Core interconnect, but it is sensitive only to the device internal power-on reset (POR). It is not affected by the L4-Core reset.

For emulator devices, the POR can also be controlled by the debugger through the JTAG® interface.

The device uses the SCM as the primary point of control for these areas:

- Pad functional input/output (I/O) multiplexing
- Pad pullup/pulldown configuration (pullup or pulldown enable)
- Pad groups associated signal integrity controls
- Device status
- Peripheral sensitivity to the microprocessor unit (MPU) and/or the digital signal processor (DSP) (IVA2.2) MSuspend signals
- Static device configuration
- Debug and observability I/O multiplexing
- Save-and-restore pad configuration

[Figure 13-1](#) provides an overview of the SCM.

Figure 13-1. SCM Overview

scm-001

The SCM primarily implements a bank of registers accessible by the software. Some are read-only registers that carry status information, and others are fully accessible (read/write).

The read/write registers are divided into the following classes:

- Pad functional multiplexing and configuration registers (32-bit registers, one register per two pins)
- Pad groups (not individual per pad) associated registers for signal integrity parameters control (32-bit read/write registers)
- Debug and observability I/O multiplexing register (32-bit read/write register)
- Static device configuration registers (32-bit read/write registers for module specific configuration)
- Scratchpad memory bank (256* 32-bit)

13.2 SCM Environment

The SCM allows the setting of external system direct memory access (sDMA) request pin sensitivity and controls the multiplexing of device internal modules signals routed to external pins for hardware debug purposes. The SCM also integrates the decoding logic of sys_boot[5:0].

[Figure 13-2](#) shows an overview of the SCM environment.

Figure 13-2. SCM Environment Overview

scm-002

The four sys_ndmreq [3:0] pins are optional external direct memory access (DMA) requests that can be managed directly by the sDMA controller. The SCM can configure these requests to either level sensitive (active low) or edge sensitive (falling edge) through the correct setting of the SENSDMAREQN bit (where N is between 0 and 3).

The sys_boot[5:0] pins are read-accessible in a status register (SYSBOOT field CONTROL.CONTROL_STATUS[5:0]) following a POR. The SCM does not use sys_boot[6] (for more information, see [Chapter 3, Power, Reset, and Clock Management](#)).

With the correct pad configuration, the SCM maps the hw_dbg[17:0] pins at the device boundary to observe hardware debug signals from device modules. The internal observable signals are PRCM signals, DMA requests, and interrupts.

13.2.1 Functional Interfaces

13.2.1.1 Basic SCM Pins

Figure 13-3 shows the SCM functional interface configured to observe device module debug signals.

Figure 13-3. SCM Interface Signals

13.2.1.2 SCM Interface Description

Table 13-1 lists the SCM input and output configured to observe device module debug signals.

Table 13-1. SCM I/O Description

Signal Name	I/O ⁽¹⁾	Description	Reset Value
hw_dbg[17:0]	O	Debug signals 0 to 17	N/A
sys_boot[5:0]	I	Boot configuration mode bits 0 to 5	per boot mode selection

⁽¹⁾ I = Input, O = Output

13.3 SCM Integration

This section describes the integration of the SCM within the device.

Figure 13-4 shows the SCM integration in the device .

Figure 13-4. SCM Integration

scm-004

The SCM is split into two blocks: the core control module in the CORE power domain, and the wake-up control module in the WKUP power domain. The wake-up control module contains the save-and-restore memory, some observability multiplexing and pad configurations. For more information about the wake-up control module, see [Section 13.4.3, Wake-Up Control Module](#).

The software sets the configuration registers to the desired values depending on the configuration of the requested device. Static device configuration registers can be set by the software at any time and are effective immediately.

The SCM is connected on the L4-Core interconnect. The power, reset, and clock management (PRCM) module provides the module interface clock (CORE_L4_ICLK) and the POR signal. The PRCM generates one global reset per power domain (CORE_RSTPWRON_RET for the CORE power domain and WKUP_RSTPWRON for the WKUP power domain). The SCM does not respond to a warm reset or to an L4 reset.

13.3.1 Clocking, Reset, and Power-Management Scheme

13.3.1.1 Clock

The main sequential logic within the SCM is accessible in a register file through the L4-Core. The only clock provided to the SCM is the interface clock, CORE_L4_ICLK. This clock comes from the PRCM module and is controlled by the PRCM.CM_ICLKEN1_CORE[6] EN_SCMCTRL bit (0 = disables the clock, 1 = enables the clock) and the PRCM.CM_AUTOIDLE1_CORE[6] AUTO_SCMCTRL bit (enables/disables automatic control of the interface clock).

For further information, see [Chapter 3, Power, Reset, and Clock Management](#).

The wake-up control module is configured through the L4-Core interface of the core control module and is accessed from the core control module through a dedicated interface. This interface uses the L4-Core interface clock (CORE_L4_ICLK) divided by 4 or 2 according to the CONTROL.[CONTROL_PADCONF_OFF\[2\]](#) WKUPCTRLCLOCKDIV bit. Only this wake-up interface clock (WKUP_ICLK) is propagated to the wake-up control module.

13.3.1.2 Resets

The SCM responds only to the internal POR and to the device type. The CONTROL.[CONTROL_SYSCONFIG\[1\]](#) SOFTRESET bit has no effect; the SCM is not affected by a warm reset.

The internal POR is not a direct image of the POR input pin (SYS_NRESPWRON). The PRCM module generates an internal POR signal per power domain and activates the internal POR when the eFuse-related settings (such as the device type) are initialized. The core control module of the CORE power domain responds to the CORE POR (CORE_RSTPWRON_RET). The wake-up control module of the WKUP power domain responds to the POR (WKUP_RSTPWRON).

NOTE: References in the TRM to the POR refer to the internal POR as seen by the SCM.

On emulator devices, the debugger can also control the internal POR signal though the JTAG interface.

For further information, see [Chapter 3, Power, Reset, and Clock Management](#).

13.3.1.3 Power Domain

The SCM is split into two blocks: the core control module, which is attached to the CORE power domain and can be in either active, retention, or off state, and the wake-up control module, which belongs to the WKUP power domain.

NOTE: The SCM is fully built with retention flip-flop.

For further information, see [Chapter 3, Power, Reset, and Clock Management](#).

13.3.1.4 Power Management

13.3.1.4.1 System Power Management

The PRCM module can require the SCM to be idled to save power. The SCM enters idle mode through the CONTROL.[CONTROL_SYSCONFIG\[4:3\]](#) IDLEMODE bit field.

The PRCM module requests idle mode, and the SCM always accepts an idle command. Idle mode can be configured to either force-idle or smart-idle mode.³

When the SCM is in force-idle mode (IDLEMODE bits CONTROL.[CONTROL_SYSCONFIG\[4:3\]](#) = 0b00) and it receives an idle request from the PRCM module (PRCM.CM_ICLKEN1_CORE[6] set to 0 or PRCM.CM_AUTOIDLE1_CORE[6] set to 1 and the L4-Core interface clock idle transitions), the SCM waits unconditionally for active system clock gating by the PRCM module. Active system clock gating occurs only when all peripherals supplied by the same L4-Core interface clock domain are also ready for idle.

In smart-idle mode (IDLEMODE bits CONTROL.[CONTROL_SYSCONFIG\[4:3\]](#) = 0b10), an idle command is accepted only when the save mechanism completes.

In idle mode (when the PRCM module has gated the interface clock), the SCM is not active and the interface clock paths are gated.

NOTE: The PRCM.CM_IDLEST1_CORE[6] ST_SCMCTRL bit (0b0 = active, 0b1 = idle) can check the SCM idle state.

The SCM idle mode is a function of the PRCM.CM_ICLKEN1_CORE[6] EN_SCMCTRL bit configuration and can be controlled automatically with hardware, depending on the PRCM.CM_AUTOIDLE1_CORE[6] AUTO_SCMCTRL bit configuration.

13.3.1.4.2 Module Power Saving

An internal interface clock-gating feature provides SCM local power management. The clock for the logic within the module can be gated when there is no access to the module according to the CONTROL.[CONTROL_SYSCONFIG\[0\]](#) AUTOIDLE bit. Otherwise, this logic is free-running on the interface clock CORE_L4_ICLK.

The L4-Core interface clock (CORE_L4_ICLK) is also used to synchronize and resample module inputs. The clock for those functions must always be free-running. Therefore, it is not gated.

The wake-up control module is clocked only by a local wake-up interface clock from the core control module. The wake-up interface clock (WKUP_ICLK) uses the L4-Core interface clock (CORE_L4_ICLK) divided by 4 or 2 to reduce power consumption according to the CONTROL.[CONTROL_PADCONF_OFF\[2\]](#) WKUPCTRLCLOCKDIV bit (0 = divided by 4; 1 = divided by 2).

Figure 13-5 shows the SCM internal clock implementation.

Figure 13-5. Internal Clock Implementation

scm-005

13.3.2 Hardware Requests

The SCM does not generate interrupt or wake-up requests.

13.4 SCM Functional Description

13.4.1 Block Diagram

The SCM controls various device modules settings through register configuration and internal signals. It also controls the pad configuration and multiplexing and the routing of internal signals (such as PRCM signals or DMA requests) to observable pins for debug.

[Figure 13-6](#) shows the SCM block diagram.

Figure 13-6. SCM Block Diagram

scm-006

The following sections describe the functionality of the SCM registers.

13.4.2 SCM Initialization

The SCM responds only to the internal POR and to the device type. At power-on, reset values for the registers define the safe state for the device. In the initialization mode, only modules used at boot time are associated with the pads. Other module inputs are internally tied, and outputs pads are turned off each time the feature is available.

For the pad configuration, pullup/pulldown fields are set according to the device pin list.

General-purpose devices include features that are inaccessible or unavailable. These inaccessible registers define the default or fixed device configuration or behavior.

13.4.3 Wake-Up Control Module

The wake-up control module in the SCM belongs to the WKUP power domain. It contains a 1K-byte memory in which to save the pad configuration registers in the core control module before going to off mode. Pad configuration registers driving the I/O pad control in the WKUP power domain are also instantiated in the wake-up control module.

The wake-up control module is configured through the L4-Core interface in the core control module and is accessed from the core control module through a dedicated interface. This interface between the core control module and the wake-up control module uses the CORE_L4_ICLK clock divided by 4 to reduce power consumption in the WKUP power domain.

13.4.4 Pad Functional Multiplexing and Configuration

After POR, the software sets the pad functional multiplexing and configuration registers to the requested device pad configurations. Data written in these registers command directly the multiplexing of the pad configuration logic.

Each pin is configurable by software using its associated pad configuration register field, which is 16 bits wide (see Figure 13-7).

Figure 13-7. Pad Configuration Register Functionality

scm-008

One pad configuration register field is available for each pin. Each 32-bit pad configuration register is grouped into two 16-bit pad configuration register fields. One pad configuration register provides control for two different pins.

Some pad configuration registers control the configuration of pads in the CORE power domain. These

registers are instantiated in the CORE power domain of the SCM (core control module, physical addresses 0x4800 2030 to 0x4800 2264 and 0x4800 25A0 to 0x4800 25F8). Pad configuration registers also control the configuration of pads in the WKUP power domain. These registers are instantiated in the WKUP power domain of the SCM (wake-up control module, physical addresses 0x4800 2A00 to 0x4800 2A24 and 0x4800 2A4C to 0x4800 2A58).

NOTE: These registers can be accessed using 8-, 16-, and 32-bit operations.

The functional bits of one pad configuration register are divided into the following five fields:

- MUXMODE (3 bits) defines the multiplexing mode applied to the pin. A mode corresponds to the selection of the functionality mapped on the pin with eight (0 to 7) possible functional modes for each pin.
- PULL (2 bits) for combinational pullup/pulldown configuration:
 - PULLTYPESELECT: Pullup/pulldown selection for the pin.
 - PULLUDENABLE: Pullup/pulldown enable for the pin.
- INPUTENABLE (1 bit) drives an input enable signal to the I/O CTRL.
 - INPUTENABLE = 0: Input Disable. Pin is configured in output only mode.
 - INPUTENABLE = 1: Input Enable. Pin is configured in bidirectional mode.
- Off mode values (5 bits) override the pin state when the OFFENABLE bit CONTROL.
CONTROL_PADCONF_X is set and off mode is active. This feature allows having separate configurations for the pins when in off mode:
 - OFFENABLE: Off mode pin state override control. Set to 1 to enable the feature and to 0 to disable it.
 - OFFOUTENABLE: Off mode output enable value. Set to 0 to enable the feature and to 1 to disable it.
 - OFFOUTVALUE: Off mode output value.
 - OFFPULLUDENABLE: Off mode pullup/pulldown enable
 - OFFPULLTYPESELECT: Off mode pullup/pulldown selection

CAUTION

The OFFOUTENABLE and OFFOUTVALUE bits are functional only if the pad configuration supports output mode on at least one MUXMODE. For a pad that supports only the input feature, the OFFOUTENABLE and OFFOUTVALUE bits cannot be configured (they are don't care and read always returns 0).

- Wake-up bits (2 bits):
 - WAKEUPENABLE: Enable wake-up detection on input. It is also the off mode input enable value.
 - WAKEUPEVENT: Wake-up event status for the pin.

Figure 13-8 shows the pad configuration functionality when off mode is inactive. For more information about off mode, see [Section 13.4.4.4, System Off Mode](#).

Figure 13-8. Pad Configuration Diagram

scm-009

13.4.4.1 Mode Selection

Table 13-2 lists the multiplexing modes and settings.

Table 13-2. Mode Selection

MUXMODE	Selected Mode
0b000	Primary mode = Mode 0
0b001	Mode 1
0b010	Mode 2
0b011	Mode 3
0b100	Mode 4
0b101	Mode 5
0b110	Mode 6
0b111	Safe mode = Mode 7

The MUXMODE field CONTROL.[CONTROL_PADCONF_X](#) defines the multiplexing mode applied to the pad. Functional modes are referred to by their decimal (from 0 to 7) or binary (from 0b000 to 0b111) representation.

For most pads, the reset value for the MUXMODE field CONTROL.[CONTROL_PADCONF_X](#) is 0b111 defining a mode referred to as the safe mode. The exceptions are pads to be used at boot time to transfer data from selected peripherals to the external flash memory.

Mode 0 is the primary mode. When mode 0 is set, the function mapped to the pin corresponds to the name of the pin.

Mode 1 to Mode 7 are possible modes for alternate functions. On each pin, some modes are used effectively for alternate functions, while other modes are unused and correspond to no functional configuration.

The safe mode avoids any risk of electrical contention by configuring the pin as an input with no functional interface mapped to it. The safe mode is used mainly as the default mode for all pins containing no mandatory interface at the release of POR.

NOTE: Some pads do not have safe mode capability, and all eight mux modes are functional (for instance: etk_d0). For such pads, safe mode can be emulated by configuring the pad in GPI (muxmode 4).

For more information about the configurable mode on each pin, see [Table 13-4](#) through [Table 13-6](#).

13.4.4.2 Pull Selection

Whichever pull value is configured, pulls are automatically disabled when a pin is configured as an output (see [Table 13-3](#)).

Table 13-3. Pull Selection

PULL		Pin Behavior
PULLTYPESELECT	PULLUDENABLE	
0b0	0b0	Pulldown selected but not activated
0b0	0b1	Pulldown selected and activated if pin is NOT configured as OUTPUT
0b1	0b0	Pullup selected but not activated
0b1	0b1	Pullup selected and activated if pin is NOT configured as OUTPUT

For more information on the pull available on each pin, see [Table 13-4](#) through [Table 13-6](#).

13.4.4.3 Pad Multiplexing Register Fields

[Table 13-4](#) through [Table 13-6](#) provide for each pad configuration register field the address offset , reset values, and associated signal name for each multiplexing mode (as set by the MUXMODE bit field). Mode 0 is always defined. Modes with no signal name are undefined for the given pad.

NOTE:

- Pad configuration registers are split into three types, which correspond to the following three tables:
 - [Table 13-4](#) lists the pad configuration registers instantiated in the CORE power domain that drive the pads in the CORE power domain.
 - [Table 13-5](#) lists the pad configuration registers instantiated in the CORE power domain that drive the D2D pads. These pads are available in stacked mode only.
 - [Table 13-6](#) lists the pad configuration registers instantiated in the WKUP power domain that drive the pads in the WKUP power domain.
- In [Table 13-4](#) through [Table 13-6](#), an empty cell indicates that the mode or pull is not available for this pin.

CONTROL_PADCONF_GPIO128[31:16]	0x4800 2A58	Reserved				gpio_129			safe_mode

NOTE: For proper functioning of the following modules, CONTROL_PADCONF_x.INPUTENABLE must be set to 1 for pads configured to drive output clocks:

- SDRC
- GPMC
- McSPII
- I2Ci
- MMCI
- McBSPi
- HSUSB HOST

NOTE: Pad names are signal names available in mode 0.

13.4.4.4 System Off Mode

When system off mode is active (`SYS_OFF_MODE` = 0b1 from the PRCM module or the `CONTROL.CONTROL_PADCONF_OFF[0]` FORCEOFFMODEENABLE bit = 0b1), the off mode values field `CONTROL.CONTROL_PADCONF_X` overrides the pad state when OFFENABLE bit `CONTROL.CONTROL_PADCONF_X` is set.

Figure 13-9 shows the off mode pad control.

Figure 13-9. Off Mode Pad Control Overview

scm-010

If off mode is active and the OFFENABLE bit is set to disable, the pad keeps the AND value of the configuration (I/O, pullup/pulldown) it had before going into off mode:

- For an input, the pad is isolated and the pull remains active.
- For an output, the value is latched before going into off mode, to drive the same value in off mode

For more information about off mode, see [Chapter 3, Power, Reset, and Clock Management](#).

For more information about the preliminary settings that must be done before performing OFF <-> ON transitions, see [Section 13.5.3, Off Mode Preliminary Settings](#).

13.4.4.4.1 Save-and-Restore Mechanism

Before going to off mode there is a context saving of the device. The save-and-restore mechanism saves the pad configuration registers (in the CORE power domain) in a WKUP power domain memory (physical addresses 0x4800 2600 to 0x4800 29FC) before going to off mode, and restores those registers when returning from off mode. This mechanism uses the dedicated wake-up interface between the core control module and the wake-up control module.

The save mechanism in the pad configuration registers is activated by setting the STARTSAVE bit `CONTROL.CONTROL_PADCONF_OFF[1]`. When all pad configuration registers have been saved to the wake-up memory, the status SAVEDONE bit `CONTROL.CONTROL_GENERAL_PURPOSE_STATUS[0]` is set. In smart-idle mode, the idleAck is returned when the save process is complete.

When returning from off mode, the registers are restored after the PRCM module asserts the START_RESTORE signal. The SCM returns a RESTORE_DONE signal to the PRCM module when the restore process completes.

Figure 13-10 shows an overview of the save-and-restore mechanism in off mode.

Figure 13-10. Save-and-Restore Mechanism Overview

scm-011

13.4.4.4.2 Wake-Up Event Detection

In off mode, wake-up event detection can also be enabled on an input pad. The pad wake-up event is latched in the WAKEUPEVENT bit CONTROL. **CONTROL_PADCONF_X**.

The off mode I/O pads wake-up scheme is enabled by setting the EN_I/O bit PRCM.PM _WKEN_WKUP[8]. The wake-up scheme status is transmitted by the WKUP_ENABLE signal. The wake-up event detection capability of each I/O pad of the device is individually enabled/disabled by writing WAKEUPENABLE bit CONTROL. **CONTROL_PADCONF_X**.

Figure 13-11 shows the overview of wake-up event detection.

Figure 13-11. Wake-Up Event Detection Overview

For more information about the wake-up sequences, see [Chapter 3, Power, Reset, and Clock Management](#).

NOTE: When wake-up detection is enabled for a pad, the pad must be configured as input to avoid contention between the device output buffer and an external driver. If this pin is already configured as an input in active mode, hardware automatically retains the same input state; no software action is required.

If this pin is configured as an output in active mode, the OFF override function must be enabled to set the pin as an input during off mode: in the CONTROL.CONTROL_PADCONF register, set OFFENABLE to 0x1 to enable the OFF override function, and set OFFOUTENABLE to 0x1 to switch this pin to input mode.

NOTE: Regardless of the INPUTENABLE bit being set high or low during active mode, to enable wake-up detection for a pad, user software must set WAKEUPENABLE bit to 0x1. It is recommended that pullup/pulldown resistors be applied at the pad to avoid spurious wake-up detection. Optionally, user software can enable the pad OFF-mode internal pullup/down resistors by appropriately setting the OFFMODEPULLUDENABLE and OFFMODEPULLTYPESELECT bits in the corresponding pad configuration register.

[Table 13-7](#) lists the bit directions of the CONTROL_PADCONF_x registers.

Table 13-7. Bit Directions for CONTROL_PADCONF_x Registers

CONTROL_PADCONF_x Bit	Bit Direction	
	0	1
PULLUDENABLE	Not activated	Activated
PULLTYPESELECT	Pulldown	Pullup
INPUTENABLE	Input enable signal inactive	Input enable signal active
OFFENABLE	Off mode values are invalid.	Off mode values are valid.
OFFOUTENABLE	Output	Input
OFFOUTVALUE	Low	High
OFFPULLUDENABLE	Not activated	Activated
OFFPULLTYPESELECT	Pulldown	Pullup
WAKEUPENABLE	Disable I/O wake-up function.	Enable I/O wake-up function.
WAKEUPEVENT	Wake-up event not detected	Detect wake-up event.

13.4.5 Extended-Drain I/O Pin and PBIAS Cells

The device mainly supports 1.8-V I/O voltage on its interfaces, with the exception of MMC/SD/SDIO1 interface, which supports both 1.8-V and 3.0-V voltages through internal PBIAS generation and extended-drain I/Os.

The need for embedded extended-drain I/Os on MMC/SD/SDIO1 interface and another interface, which is supported as the GPIO interface in the GP device, imposes the use of embedded PBIAS cells to provide 1.8-V or 3.0-V reference voltage. The PBIAS cells and the extended-drain I/Os are software-controlled by bits located in the CONTROL.[CONTROL_PBIAS_LITE](#), CONTROL.[CONTROL_PROG_IO1](#) and CONTROL.[CONTROL_WKUP_CTRL](#) registers of the SCM. See [Section 13.6.3, Register Descriptions](#), for the description of these registers.

[Figure 13-12](#) shows the functional block diagram between the PBIAS cells and the extended-drain I/O cells.

Figure 13-12. Functional Block Diagram

[Table 13-8](#) describes the CONTROL.[CONTROL_PBIAS_LITE](#), CONTROL.[CONTROL_PROG_IO1](#) and CONTROL.[CONTROL_WKUP_CTRL](#) bit controls for the PBIAS and the extended-drain I/O cells.

Table 13-8. PBIAS Cell and Extended-Drain I/O Pin Bit Controls

Control Signals for PBIAS0 and/or Associated Extended-Drain I/O Cell	Control Signals for PBIAS1 and/or Associated Extended-Drain I/O Cell	Description
PBIASLITEPWRDNZ0	PBIASLITEPWRDNZ1	The PBIASLITEPWRDNZ0 bit is used to protect the PBIAS0 cell when the SDMMC1_VDDS power supply voltage is not stable. The PBIASLITEPWRDNZ1 bit is used to protect the PBIAS1 cell when the SIM_VDDS power supply voltage is not stable. Software must keep the PBIASLITEPWRDNZ0/PBIASLITEPWRDNZ1 signal to 0b0 whenever the SDMMC1_VDDS/SIM_VDDS signal is ramping. When this bit is set to 0, the PAD is floating.
PBIASLITEPWRDNZ0	GPIO_IO_PWRDNZ	The same PBIASLITEPWRDNZ0 bit that controls power-down mode for the PBIAS0 cell is also used to control power-down mode for its associated MMC1 extended-drain I/O cell (see Figure 13-12). A second extended-drain I/O cell (associated GPIO pads) does not share the same power-down control with the PBIAS1 cell, as the MMC/SD/SDIO1 I/O cell does with the PBIAS0 cell. A separate power-down control, GPIO_IO_PWRDNZ, which resides in a different register (CONTROL.CONTROL_WKUP_CTRL) is used to power it down. (See Figure 13-12)
PBIASLITEVMODE0	PBIASLITEVMODE1	Bit that controls SDMMC1_VDDS / SIM_VDDS voltage level. Default state of this bit is HIGH, indicating SDMMC1_VDDS/SIM_VDDS = 3.0 V
PBIASLITESUPPLYHIGH0	PBIASLITESUPPLYHIGH1	Bit that describes whether the SDMMC1_VDDS/SIM_VDDS supply is 3.0 V or 1.8 V
PRG_SDMMC1_SPEEDCTRL	-	Bit that controls the extended-drain MMC1 I/O cell speed. The control is in the CONTROL.CONTROL_PROG_IO1 register. The second extended-drain I/O cell (GPIO pads associated) does not have speed control.
PBIASLITEVMODEERROR0	PBIASLITEVMODEERROR1	Status indicating whether the software-programmed VMODE level matches the SUPPLY_HI output signal
PBIAS0_ERROR	PBIAS1_ERROR	This signal determines whether the software-programmed PBIASLITVMODEx level matches PBIASLITESUPPLYHIGHx. This signal is generated only when PBIASLITEVMODEENx is high.

Table 13-9 lists the power supplies for the PBIAS and the extended-drain I/O cells.

Table 13-9. Power Supplies

Name	Description
VDD2	Core voltage supply
SDMMC1_VDDS or SIM_VDDS (vdds_sdmmc1 or vdds_sim power pins of the device)	I/O supply voltage nominal 1.8 V/ 3.0 V
VDDS	1.8-V supply for the input buffer

13.4.5.1 PBIAS Cells

The PBIAS0 cell provides a bias for the extended-drain I/O cell used with high voltage for the MMC/SD/SDIO1 interface.

NOTE: With the appropriate configuration of the PBIAS0 cell, the gpio_120 through gpio_125 I/Os (MuxMode = 0x4) can operate in 3-V mode.

The PBIAS1 cell provides a bias for a second extended-drain I/O cell.

NOTE: With the appropriate PBIAS1 cell configuration, the gpio_126, gpio_127, and gpio_129 I/Os (MuxMode = 0x4) can operate in 3-V mode.

NOTE: Unlike gpio_126, gpio_127, and gpio_129, gpio_128 (MuxMode = 0x4) is not in the SIM_VDDS voltage domain, and does not require PBIAS1 cell configuration. It is internally supplied in the standard 1.8-V VDDS_IO voltage domain, and does not support 3-V mode.

PBIAS0 and PBIAS1 cells provide a voltage reference (PBIAS voltage) for biasing extended drain in the MMC/SD/SDIO1 and GPIO associated I/O cells. In addition to generating the bias voltage, the PBIAS0 cell can detect the supply voltage (SDMMC1_VDDS) value (1.8V or 3.0 V) and update, with its status, the PBIASLITESUPPLYHIGH0. In addition to generating the bias voltage, the PBIAS1 cell can detect the supply voltage (SIM_VDDS) value (1.8 V or 3.0 V) and update it with its PBIASLITESUPPLYHIGH1 status bit.

CAUTION

A PBIAS cell lets the peripheral associated with its corresponding extended-drain I/O cell support 1.8-V and 3.0-V voltages. A PBIAS cell is not a part of a peripheral, but a part of the device I/Os to which this peripheral is internally connected. These device I/Os are not exclusive to only one peripheral; through I/O multiplexing they can be connected to other internal signals. It is necessary to configure the PBIAS and corresponding I/O cell to enable the I/Os, regardless of how I/O multiplexing is configured for these device I/Os. In other words, independently of which signal is internally connected to a device I/O powered by SDMMC1_VDDS or SIM_VDDS, the corresponding PBIAS must be configured.

13.4.5.2 Extended-Drain I/Os

On the device, the following extended-drain I/Os are used by I/Os from the MMC/SD/SDIO1:

- sdmmc1_clk
- sdmmc1_cmd
- sdmmc1_dat_i (where i = 0 to 3)

The following extended-drain I/Os are used by GPIO I/Os:

- gpio_126 (MuxMode = 0x4)
- gpio_127 (MuxMode = 0x4)
- gpio_129 (MuxMode = 0x4)

[Figure 13-13](#) describes the extended-drain I/O cell.

Figure 13-13. Extended-Drain I/O

scm-016

The extended-drain I/O cells have the following I/O signals:

- Output signal, input signal, and oe, which comes from the selected IO module with the correct MODE field CONTROL.[CONTROL_PADCONF_X](#) configuration.

NOTE: The two extended-drain I/Os are muxed I/Os with mode and pullup/pulldown configurations programmable in the SCM.

- The PBIAS voltage is a voltage reference for biasing the extended-drain in the MMC/SD/SDIO1I/O and GPIO-associated I/O cells (gpio_126, gpio_127, and gpio_129).
- The PBIASLITEPWRDNZ0 bit is used to protect the MMC/SD/SDIO1 I/O cell when the SDMMC1_VDDS voltage is not stable.
- The GPIO_IO_PWRDNZ bit is used to protect the GPIO-associated I/O cell when the SIM_VDDS voltage is not stable.

CAUTION

Software must keep the PWRDNZ-related signals to 0b0 when the SDMMC1_VDDS or SIM_VDDS signal is ramping up/down or changing. When PBIASLITEPWRDNZ0/PBIASLITEPWRDNZ1 is 0, the PAD is floating (the PAD may not reflect the state of the output signal, and the input signal may not reflect the state of the PAD).

CAUTION

It is strongly recommended to synchronize any changes of the PBIASLITEPWRDNZ1 and GPIO_IO_PWRDNZ bits (that is, both bits should be set to 1 or 0 at the same time).

- The CONTROL.[CONTROL_PROG_I01](#)[20] PRG_SDMMC1_SPEEDCTRL bit controls the speed of the MMC/SD/SDIO1 I/O cell and can be used to reduce dynamic current if fast rise/fall times are not

required.

- The PBIASLITESUPPLYHIGH0 bit is a status bit on the SDMMC1_VDDS value and is used to inform the PBIAS0 cell on the value of SDMMC1_VDDS signal.
- The PBIASLITESUPPLYHIGH1 bit is a status bit on the SIM_VDDS value and is used to inform the PBIAS1 cell on the value of the SIM_VDDS signal.

For more information about the software configurations of the extended-drain I/Os and PBIAS cells, see [Section 13.5.2, Extended-Drain I/Os and PBIAS Cells Programming Guide](#).

13.4.6 Band Gap Voltage and Temperature Sensor

The device supplies a voltage reference and a temperature sensor feature which are gathered in the band gap voltage and temperature sensor (BGAPTS) module. The band gap provides current and voltage reference for its internal circuits and also to other analog IP blocks. The A/D converter (ADC) produces an output value that is proportional to the silicon temperature.

Main features of the BGAPTS module are:

- A constant voltage reference output: 0.5 V
- Four constant current reference outputs of 1 μ A
- Analog supply is a nominal 1.8 V.
- Small A/D converter with 8-bit digital output
- OFF mode compatible
- Thermal shutdown comparator output

The band gap and the temperature sensor are software-controlled by bits located in the CONTROL.[CONTROL_TEMP_SENSOR](#) and the CONTROL.[CONTROL_BGAPTS_WKUP](#) registers of the SCM. The CONTROL.[CONTROL_BGAPTS_WKUP](#) register is used to control certain inputs of the BGAPTS module in the core domain. The register is placed in wake-up domain control module so that software can program these controls appropriately before the core domain is ON. See [Table 13-279](#), for more information about this register. See [Section 13.4.7.5, Register Descriptions](#), for the description of this register.

[Figure 13-14](#) shows the functional block diagram of the band gap and the temperature sensor module.

Figure 13-14. Functional Block Diagram

Table 13-10 describes the input and output signals for the band gap and the temperature sensor.

Table 13-10. Band Gap Voltage and Temperature Sensor Signals Description

Pin	I/O ⁽¹⁾	Description
SOC	I	Start Of Conversion signal. A transition to high starts a new ADC conversion cycle.
EOCZ	I	End of Conversion signal. When low, the signal indicates that the value of TEMP[6:0] is valid.
TEMP[7:0]	O	Temperature data from the temperature sensor. This value is valid when EOCZ is low.
CONTCONV	I	Configures the temperature sensor in continuous conversion mode. 0 – ADC single conversion mode 1 – ADC continuous conversion mode
TSHUT	O	Thermal shutdown comparator output. The signal is low during normal operation and goes high during a thermal shutdown event.
RESET	I	When low the temperature sensor is in RESET mode. This signal needs to be LOW when OFFMODE is HIGH.
32K_FCLK	I	32-kHz functional clock from the CORE domain used by the temperature sensor during temperature conversion.

⁽¹⁾ I=Input, O=Output

All the configuration signals are available through the CONTROL.CONTROL_TEMP_SENSOR register.

NOTE: BGAPTS 32K_FCLK is used only for the temperature sensor. When ADC is not converting, this clock can be switched off (32K_FCLK = 0). In this case, TEMP[7:0] retains the temperature code obtained at the previous conversion.

13.4.6.1 Band Gap Voltage Reference

The band gap voltage reference feature provides several constant voltage and current references for its internal circuits, but also for other analog modules.

The voltage reference signal is a 0.5-V output that is used internally by the module and is exported for external modules or for tests.

The current reference signals consist in four lines that each supply a 1- μ A current with a 1.8-V voltage. These lines can be used to bias other modules.

13.4.6.2 Temperature Sensor

The temperature sensor feature is used to convert the temperature of the device into a decimal value coded on 7 bits. An internal ADC (realized with a resistor array) is used for conversion. The recommended operating temperatures must be from -40 to 125°C for standard conversion, and can go up to 160°C when using the thermal shutdown comparator output (TSHUT signal). This signal indicates a too high temperature of the device. This signal is internally connected to a general purpose input/output (GPIO) pin. See [Chapter 25, General-Purpose Interface](#), for more information.

The temperature sensor offers two operating modes: a single conversion mode and a continuous conversion mode.

13.4.6.2.1 Single Conversion Mode (CONTCONV = 0)

When the ADC is idle ($\text{EOCZ} = 0$), it is possible to ask for a single temperature conversion. To initiate a new conversion, the start of conversion (SOC) signal must be asserted and maintained high until the end of conversion (EOCZ) signal goes high, after which the SOC must be made low by writing 0 to the CONTROL.[CONTROL_TEMP_SENSOR\[9\]](#) SOC bit. Conversion completion is indicated by a negative edge on EOCZ (CONTROL.[CONTROL_TEMP_SENSOR\[8\]](#) EOCZ bit).

Figure 13-15 shows the timing sequence for a single temperature conversion.

Figure 13-15. Single Conversion Mode (CONTCONV = 0)

scm-031

13.4.6.2.2 Continuous Conversion Mode (CONTCONV = 1)

When the ADC is idle ($\text{EOCZ} = 0$), it is possible to ask for a single temperature conversion. To initiate a new conversion, the SOC signal must be asserted and maintained high until the EOCZ signal goes high, after which the SOC must be made low by writing 0 to the CONTROL.[CONTROL_TEMP_SENSOR\[9\]](#) SOC bit. The ADC starts converting continuously, and when a conversion is complete, data is written to the CONTROL.[CONTROL_TEMP_SENSOR\[7:0\]](#) TEMP bits and EOCZ goes low after four clock cycles.

Figure 13-16 shows the timing sequence for a continuous temperature conversion.

Figure 13-16. Continuous Conversion Mode (CONTCONV = 1)

13.4.6.2.3 ADC Codes Versus Temperature

Table 13-11 gives the temperature corresponding to each value of the CONTROL.CONTROL_TEMP_SENSOR[7:0] TEMP bits.

Table 13-11. ADC Code Versus Temperature

ADC Code	Temperature °C		ADC Code	Temperature °C		ADC Code	Temperature °C		ADC Code	Temperature °C	
	From	To		From	To		From	To		From	To
0	-40	-40	32	-5	-3.5	64	50	52	96	105	107
1	-40	-40	33	-3.5	-1.5	65	52	53.5	97	107	109
2	-40	-40	34	-1.5	0	66	53.5	55	98	109	111
3	-40	-40	35	0	2	67	55	57	99	111	113
4	-40	-40	36	2	3.5	68	57	58.5	100	113	115
5	-40	-40	37	3.5	5	69	58.5	60	101	115	117
6	-40	-40	38	5	6.5	70	60	62	102	117	118.5
7	-40	-40	39	6.5	8.5	71	62	64	103	118.5	120
8	-40	-40	40	8.5	10	72	64	66	104	120	122
9	-40	-40	41	10	12	73	66	68	105	122	123.5

11	-40	-40	43	13.5	15	75	70	71.5	107	125	125
12	-40	-40	44	15	17	76	71.5	73.5	108	125	125
13	-40	-38	45	17	19	77	73.5	75	109	125	125
14	-38	-35	46	19	21	78	75	77	110	125	125
15	-35	-34	47	21	23	79	77	78.5	111	125	125
16	-34	-32	48	23	25	80	78.5	80	112	125	125
17	-32	-30	49	25	27	81	80	82	113	125	125
18	-30	-28	50	27	28.5	82	82	83.5	114	125	125
19	-28	-26	51	28.5	30	83	83.5	85	115	125	125
20	-26	-24	52	30	32	84	85	87	116	125	125
21	-24	-22	53	32	33.5	85	87	88.5	117	125	125
22	-22	-20	54	33.5	35	86	88.5	90	118	125	125
23	-20	-18.5	55	35	37	87	90	92	119	125	125
24	-18.5	-17	56	37	38.5	88	92	93.5	120	125	125
25	-17	-15	57	38.5	40	89	93.5	95	121	125	125
26	-15	-13.5	58	40	42	90	95	97	122	125	125
27	-13.5	-12	59	42	43.5	91	97	98.5	123	125	125
28	-12	-10	60	43.5	45	92	98.5	100	124	125	125

Table 13-11. ADC Code Versus Temperature (continued)

ADC Code	Temperature °C		ADC Code	Temperature °C		ADC Code	Temperature °C		ADC Code	Temperature °C	
29	-10	-8	61	45	47	93	100	102	125	125	125
30	-8	-6.5	62	47	48.5	94	102	103.5	126	125	125
31	-6.5	-5	63	48.5	50	95	103.5	105	127	125	125

NOTE: ADC code values in the subrange 128–255 are reserved for future use.

13.4.7 Functional Register Description

13.4.7.1 Static Device Configuration Registers

Table 13-12 describes the static device configuration registers.

Table 13-12. Static Device Configuration Registers

Physical Address	Register Name	Description	Access
0x4800 2274	CONTROL_DEVCONF0	Module dedicated configurations	R/W
0x4800 22D8	CONTROL_DEVCONF1	Module dedicated configurations	R/W

These registers allow the static configuration of device modules such as USB, McBSP, SDMMC/SD/SDIO. For example, they allow selecting external or internal clocks for McBSP modules.

13.4.7.2 MPU and/or DSP (IVA2.2) MSuspend Configuration Registers

Table 13-13 describes the MPU and/or DSP (IVA2.2) MSuspend configuration registers.

Table 13-13. MSuspendMux Control Registers

Physical Address	Register Name	Description	Access
0x4800 2290	CONTROL_MSUSPENDMUX_0	Control the use of MSuspend signals at module level	R/W
0x4800 2294	CONTROL_MSUSPENDMUX_1		R/W
0x4800 2298	CONTROL_MSUSPENDMUX_2		R/W
0x4800 229C	CONTROL_MSUSPENDMUX_3		R/W
0x4800 22A0	CONTROL_MSUSPENDMUX_4		R/W
0x4800 22A4	CONTROL_MSUSPENDMUX_5		R/W

These registers provide an entry for each module that must consider the MSuspend signals from the processors (MPU and/or DSP). For each module, the sensitivity to the MSuspend signals is defined within five possibilities (coded using 3 bits):

- 0b000: No sensitivity; no MSuspend signal reaches the module.
- 0b001: Sensitivity to the MPU MSuspend signal (the DSP signal is ignored)
- 0b010: Sensitivity to the DSP MSuspend signal (the MPU signal is ignored)
- 0b011: Sensitivity to the logical ORed MPU and DSP MSuspend signals
- 0b100: Sensitivity to the logical ANDed MPU and DSP MSuspend signals
- Other values: No sensitivity; no MSuspend signal reaches the module.

The logic used to combine the MSuspend signals from the processors is implemented within the SCM. MSuspend signals are active low.

CAUTION

Use care when using combined sensitivity settings (ANDing or ORing DSP and MPU MSuspend signals).

ORing the DSP and MPU MSuspend signals creates a situation where the module is suspended when at least one processor is under debug; therefore, when one processor is halted, stepping within the code of the other one does not change the module suspended state.

Not all modules use the MSUSPEND signal. See the TRM chapter for each module to determine whether the module supports the MSUSPEND signal.

All MSUSPEND signals coming out of the MPU and DSP are resynchronized within the SCM by using the control module interface clock.

13.4.7.3 IVA2.2 Boot Registers

[Table 13-14](#) describes the IVA2.2 boot registers.

Table 13-14. IVA2.2 Boot Registers

Physical Address	Register Name	Description	Access
0x4800 2400	CONTROL_IVA2_BOOTADDR	IVA2.2 boot loader address register	R/W
0x4800 2404	CONTROL_IVA2_BOOTMOD	IVA2.2 boot mode register	R/W

The CONTROL.[CONTROL_IVA2_BOOTADDR](#) register defines the physical address for the IVA2 boot loader and drives the IVA2_BOOTADDR[21:0] signals out from the control block to the IVA2 subsystem.

The CONTROL.[CONTROL_IVA2_BOOTMOD](#) register defines the IVA2 boot mode and drives the IVA2_BOOTMOD[3:0] signals out from the control block to the IVA2.2 subsystem. Based on the value of IVA2_BOOTMOD[3:0], the ROM boot loader executes different boot modes of IVA2.2.

[Table 13-15](#) lists the IVA2.2 boot modes.

Table 13-15. IVA2.2 Boot Modes

IVA2_BOOTMOD[3:0] Value	Meaning
0x0	Direct boot: The ROM loader is not executed. Instead, IVA2.2 directly starts executing the bootstrap at the address contained in the CONTROL_IVA2_BOOTADDR register.
0x1	Idle boot: The boot loader executes the IDLE instruction.
0x2	Wait in self-loop boot: The boot loader puts IVA2.2 in a self-loop.
0x3	User-defined bootstrap mode: The boot loader copies the boot strap into internal memory and branches to it.
0x4	The boot loader executes the default context restore code, which is part of the ROM boot loader.

For further information, see [Chapter 5, IVA2.2 Subsystem](#).

13.4.7.4 PBIAS LITE Control Register

[Table 13-16](#) describes the CONTROL.[CONTROL_PBIAS_LITE](#) register, which controls most of the settings of the PBIAS0, PBIAS1 cells and their associated extended-drain I/O cells.

Table 13-16. PBIAS Control Register

Physical Address	Register Name	Description	Access
0x4800 2520	CONTROL_PBIAS_LITE	Control settings for PBIAS and extended-drain I/O cells	R/W

For more information about the PBIAS0 and PBIAS1 cells, see [Section 13.4.5, Extended-Drain I/O Pin and PBIAS Cells](#).

13.4.7.5 Temperature Sensor Control Register

[Table 13-17](#) describes the CONTROL.CONTROL_TEMP_SENSOR register, which controls the temperature sensor.

Table 13-17. Temperature Sensor Register

Physical Address	Register Name	Description	Access
0x4800 2524	CONTROL_TEMP_SENSOR	Temperature sensor control register	R/W

13.4.7.6 Signal Integrity Parameter Control Registers With Pad Group Assignment

13.4.7.6.1 Signal Integrity Parameter Controls Overview

Most of the I/O cells associated to the device pads are configurable/controllable to deliver their carried signals to the targeted sink with maximum signal integrity. Configuration of the buffers is done by groups assignment and not individually per pad. The I/Os parameter control includes : drive strength in terms of frequency vs. load settings (SDRC) - DS, far-end load settings -LB (GPMC, etc.) , combined slew rate -SC and load capacitance vs effective transmission line (TL) length - LB controls (UART3, etc.), pullup strength (SDMMC) settings, pullup resistance vs capacitance load settings (I2Cx).

The pad group assigned signal integrity controls are provided through the registers described in [Table 13-18](#), Signal Integrity Parameter Control Registers.

Table 13-18. Signal Integrity Parameter Control Registers

Physical Address	Register Name	Description	Access
0x4800 2444	CONTROL_PROG_IO0	I/O pad group assignment control register	R/W
0x4800 2448	CONTROL_PROG_IO1	I/O pad group assignment control register	R/W
0x4800 2408	CONTROL_PROG_IO2	I/O pad group assignment control register	R/W
0x4800 2A80	CONTROL_PROG_IO_WKUP1	I/O pad group assignment control register in the WKUP domain	R/W

13.4.7.6.2 DDR Buffer Drive Strength Related Settings

The DS control maintains the same drive strength by applying programmable capacitance load compensation at the I/O level. This is done to achieve the necessary performance of the DDR driver output groups at different target frequencies.

[Table 13-19](#) provides the DS programming pattern. The DS controls concern only the SDRC I/Os of the device.

Table 13-19. DS Parameter Settings

DDR I/Os Drive Strength Setting for High-Speed I/O Cells	
DS = 0b0	DS = 0b1
Equivalent load capacitance range: 2–4 pF	Equivalent load capacitance range: 4–12 pF

13.4.7.6.3 High Speed I/Os Far End Load Settings

[Table 13-20](#) provides the far-end-load range programming pattern applicable to high-speed I/Os. Control over this signal group parameter is acquired through programming single-bit LB.

Table 13-20. LB Parameter Settings for High-Speed I/O Cells**Far End Load Setting on TL for High-Speed I/O Cells**

LB = 0b0	LB = 0b1
Equivalent load capacitance: 1–10pF	Equivalent load capacitance: 10–16pF

NOTE: For both capacitance load ranges, the TL length must be maintained in the range [1cm–6cm].

13.4.7.6.4 Low-Speed I/Os Combined Slew Rate vs TL Length and Load Settings

[Table 13-21](#) and [Table 13-22](#) provide the recommended SC [1:0] (slew-rate control) vs LB [1:0] (combined capacitance load and TL length control) programming pattern applicable to low-speed I/O cells. The SR settings determine three target maximal frequencies of I/O operation.

Because the TL and SC parameter values are mutually constrained in the context of a certain I/O signal transient performance, only the combined slew rate vs TL length/capacitance load settings make sense. [Table 13-21](#) and [Table 13-22](#) list the possible SC[1:0]–LB[1:0] combinations.

Table 13-21. Recommended SC vs LB Parameter Settings for TL With Length in the Range 2–20cm**SC vs LB Settings Applicable to pads in Low-Speed I/O Cells**

SC[1:0] = 00 LB[1:0] = 00	SC[1:0] = 01 LB[1:0] = 10	SC[1:0] = 10 LB[1:0] = 10
2–20 cm 1–10pF achieved pad Freq <= 20MHz	2–20 cm 10–20pF achieved pad Freq <= 60MHz	2–20 cm 10–20pF achieved pad Freq <= 40MHz

Table 13-22. Recommended SC vs LB Parameter Settings for Dual TL With Length in the Range 20–40cm**SC vs LB Settings Applicable to Pads in Low-Speed I/O Cells**

SC[1:0] = 00 LB[1:0] = 01	SC[1:0] = 01 LB[1:0] = 11	SC[1:0] = 10 LB[1:0] = 11
20–40 cm (dual TL) 1–10 pF achieved pad Freq <= 20MHz	20–40 cm (dual TL) 10–20 pF achieved pad Freq <= 60MHz	20–40 cm (dual TL) 10–20pF achieved pad Freq <= 40MHz

CAUTION

It is strongly recommended that only the SC vs LB combinations given in the [Table 13-21](#) and [Table 13-22](#) are used when programming low-speed I/Os.

13.4.7.6.5 SDMMC Pullup Strength Control

A control bit, PRG_SDMMC_PUSTRENGTH, is added in the register CONTROL_PROG_IO0 to program the pullup strength for the MMC/SD/SDIO1 I/O group. [Table 13-23](#) lists the supported resistance ranges.

Table 13-23. Group Pullup Strength Setting for SDMMC1 I/Os**PUSTRENGTH Control**

PRG_SDMMC_PUSTRENGTH = 0b0	PRG_SDMMC_PUSTRENGTH = 0b1
Pullup with 50–110 kΩ strength selected	Pullup with 10–50 kΩ strength selected

13.4.7.6.6 I²Cx I/Os Group Pullupresx Controls and Load Range Settings

[Table 13-24](#) provides examples of pullup resistance versus load range I²Cx I/O signal integrity control capabilities. Three possible operation modes of the I²C associated I/O cells are shown: non-I²C mode, full-speed (FS), and high-speed (HS) modes, which are described in [Chapter 17, Multimaster High-Speed I²C Controller](#). Non-I²C mode means that the muxmode field in I²Cx dedicated PADCONFS is set to select signals different than I²C signals. For more information, see [Section 13.4.4.3, Pad Multiplexing Register Fields](#).

Table 13-24. Example I²Cx Pullupresx vs I²C LB Parameter Settings in Different Modes

Non-I ² C Mode	FS I ² C Bus Mode	HS I ² C p2p Mode
nmode = 1 hsmode = 0 pullupresx = 1 lb[1:0] = 00	nmode = 0 hsmode = 0 pullupresx = 1 lb[1:0] = 00 400 kHz external PU	nmode = 0 hsmode = 1 pullupresx = 0 lb[1:0] = 00 3.4 MHz, cap.load 5–12pF

The I²Cx buffer contains internal pullup resistors for fast and high-speed modes that meet the I²C rise time specifications for loads up to 80 pF in high-speed mode and 150 pF in fast mode. LB[1:0] signals can be used to select the appropriate pullup resistor for a given load range. [Table 13-25](#) lists the configuration options.

Table 13-25. Internal Pullup Resistor in Fast/HS Mode

LB1	LB0	Load Range HS Mode (pf)	Nominal Resistance in HS Mode (Ω)	Load Range Fast Mode (pf)	Nominal Resistance in Fast Mode (Ω)
0	0	5–12	1.66K	5–15	4.5K
0	1	12–25	920	15–50	2.1K
1	0	25–50	500	50–150	860
1	1	50–80	300	–	–

I²C I/Os can meet I²C rise/fall time specifications in 1.2-V/1.8-V mode under all modes up to 400 pF, if a suitable external pullup resistor is used.

The type of pullup resistor (external or internal) for a certain I²Cx I/O group (where x = 1 to 4) is selected through the PRG_I²Cx_PULLUPRESX bit. Internal pullups are activated when PRG_I²Cx_PULLUPRESX = 0b0.

NOTE: I²C functionality is not ensured if the weak internal pullup or pulldown (100 μA nominal PU-PD) is activated on any of the I/Os connected to the bus.

13.4.7.6.7 Device Interfaces Signal Group Controls Mapping

[Table 13-26](#) describes the mapping of the different signal integrity control bit fields in the CONTROL_PROG_IOx (where x = 0 to 3) and [CONTROL_PROG_IO_WKUP1](#) registers to their assigned groups of different interface I/O pads.

Table 13-26. Signal Group Parameter Controls to Different Interface I/O Pads Mapping

Pad Group Configurable Interface	Bit Fields for Pad Group Control	Pads in Group	Type of I/O Group-Associated Control Bit Fields
SDRC	CONTROL.CONTROL_PROG_I_O0[31]SDRC_LOWDATA	sdrc_d0 - sdrc_d15 ; sdrc_dqs0 ; sdrc_dqs1 ; sdrc_dm0 ; sdrc_dm1	DS control (for more information, see Table 13-19)

Table 13-26. Signal Group Parameter Controls to Different Interface I/O Pads Mapping (continued)

Pad Group Configurable Interface	Bit Fields for Pad Group Control	Pads in Group	Type of I/O Group-Associated Control Bit Fields
	CONTROL.CONTROL_PROG_I OO[30]SDRC_HIGHDATA	sdrc_d16 - sdrc_d31 ; sdrc_dqs2 ; sdrc_dqs3 ; sdrc_dm2 ; sdrc_dm3	
	CONTROL.CONTROL_PROG_I OO[29]SDRC_ADDRCTR	sdrc_nrás ; sdrc_ncas ; sdrc_nwe ; sdrc_nclk ; sdrc_clk ; sdrc_ba0 ; sdrc_ba1	
	CONTROL.CONTROL_PROG_I OO[28]SDRC_NCS0	sdrc_ncs0 ; sdrc_cke0	
	CONTROL.CONTROL_PROG_I OO[27]SDRC_NCS1	sdrc_ncs1 ; sdrc_cke1	
GPMC	CONTROL.CONTROL_PROG_I OO[26]PRG_GPMC_A1_LB	gpmc_a1	High-speed I/O single-bit LB control (for more information, see Table 13-20)
	CONTROL.CONTROL_PROG_I OO[25]PRG_GPMC_A2_LB	gpmc_a2	
	CONTROL.CONTROL_PROG_I OO[24]PRG_GPMC_A3_LB	gpmc_a3	
	CONTROL.CONTROL_PROG_I OO[23]PRG_GPMC_A4_LB	gpmc_a4	
	CONTROL.CONTROL_PROG_I OO[22]PRG_GPMC_A5_LB	gpmc_a5	
	CONTROL.CONTROL_PROG_I OO[21]PRG_GPMC_A6_LB	gpmc_a6	
	CONTROL.CONTROL_PROG_I OO[20]PRG_GPMC_A7_LB	gpmc_a7	
	CONTROL.CONTROL_PROG_I OO[19]PRG_GPMC_A8_LB	gpmc_a8	
	CONTROL.CONTROL_PROG_I OO[18]PRG_GPMC_A9_LB	gpmc_a9	
	CONTROL.CONTROL_PROG_I OO[17]PRG_GPMC_A10_LB	gpmc_a10	
GPMC	CONTROL.CONTROL_PROG_I OO[16]PRG_GPMC_A11_LB	gpmc_a11	High-speed I/O single-bit LB control (for more information, see Table 13-20)
	CONTROL.CONTROL_PROG_I OO[15]PRG_GPMC_MIN_CFG_LB	gpmc_d0 - gpmc_d7; gpmc_wait0 ; gpmc_nadv_ale ; gpmc_noe ; gpmc_nwe ;	
	CONTROL.CONTROL_PROG_I OO[14]PRG_GPMC_D8_D15_LB	gpmc_d8 - gpmc_d15	
	CONTROL.CONTROL_PROG_I OO[13]PRG_GPMC_NCS0_LB	gpmc_ncs0	
	CONTROL.CONTROL_PROG_I OO[12]PRG_GPMC_NCS1_LB	gpmc_ncs1	
	CONTROL.CONTROL_PROG_I OO[11]PRG_GPMC_NCS2_LB	gpmc_ncs2	
	CONTROL.CONTROL_PROG_I OO[10]PRG_GPMC_NCS3_LB	gpmc_ncs3	
	CONTROL.CONTROL_PROG_I OO[9]PRG_GPMC_NCS4_LB	gpmc_ncs4	

Table 13-26. Signal Group Parameter Controls to Different Interface I/O Pads Mapping (continued)

Pad Group Configurable Interface	Bit Fields for Pad Group Control	Pads in Group	Type of I/O Group-Associated Control Bit Fields
	CONTROL.CONTROL_PROG_I_O0[8]PRG_GPMC_NCS5_LB	gpmc_ncs5	
	CONTROL.CONTROL_PROG_I_O0[7]PRG_GPMC_NCS6_LB	gpmc_ncs6	
	CONTROL.CONTROL_PROG_I_O0[6]PRG_GPMC_NCS7_LB	gpmc_ncs7	
	CONTROL.CONTROL_PROG_I_O0[5]PRG_GPMC_CLK_LB	gpmc_clk

	CONTROL.CONTROL_PROG_I O_WKUP1[14:13]PRG_CLKOUT1_SC; CONTROL.CONTROL_PROG_I O_WKUP1[12:11]PRG_CLKOUT1_LB	sys_clkout1	

Table 13-26. Signal Group Parameter Controls to Different Interface I/O Pads Mapping (continued)

Pad Group Configurable Interface	Bit Fields for Pad Group Control	Pads in Group	Type of I/O Group-Associated Control Bit Fields
	CONTROL.CONTROL_PROG_I_O_WKUP1[9:8]PRG_GPIO_128_SC; CONTROL.CONTROL_PROG_I_O_WKUP1[7:6]PRG_GPIO_128_LB	gpio_128	

13.4.8 Protection Status Registers

Table 13-27 lists the status registers.

Table 13-27. Protection Status Registers

Physical Address	Register Name	Description	Access
0x4800 22E4	CONTROL.PROT_ERR_STATUS	Protection error status register	Public (R)
0x4800 22E8	CONTROL.PROT_ERR_STATUS_DEBUG UG	Protection error status register debug	Public (R)

These registers do not depend on the device type.

The [CONTROL.CONTROL_PROT_ERR_STATUS](#), and [CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG](#) registers can be read in public mode, but cannot be written.

These bits are cleared when the L3 and L4 firewall embedded error log registers are cleared. All bits in these registers reflect device internal events related to the device protection.

On a specific event (signal rising edge), the corresponding bit is set. On a rising edge, the input signal must stay high for at least two interface clocks periods to be recognized. Software must clear each bit after reviewing the events.

When a protection violation occurs, the following bits are set:

- In application mode:
 - [CONTROL.CONTROL_PROT_ERR_STATUS \[00\]](#) = OCM-ROM protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS \[01\]](#) = OCM-RAM protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS \[02\]](#) = GPMC protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS \[04\]](#) = SMS protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS \[06\]](#) = IVA2.2 protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS \[07\]](#) = L4-Core protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS \[12\]](#) = L3 RT protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS \[15\]](#) = D2D protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS \[16\]](#) = L4-Peri protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS \[17\]](#) = L4-Emu protection violation
- In debug mode:
 - [CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG \[00\]](#) = OCM-ROM protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG \[01\]](#) = OCM-RAM protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG \[02\]](#) = GPMC protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG \[03\]](#) = SMS protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG \[06\]](#) = IVA2.2 protection violation
 - [CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG \[12\]](#) = L3 RT protection violation

For more information, see [Chapter 9, Interconnect](#).

13.4.9 SDRC Registers

[Table 13-28](#) lists the SDRAM controller (SDRC) registers, which export reset values to the SDRC registers.

Table 13-28. SDRC Registers

Physical Address	Register Name	Description	Access
0x4800 2460	CONTROL_SDRC_SHARING	SDRC sharing configuration	R/W
0x4800 2464	CONTROL_SDRC_MCFG0	SDRC configuration register 0	R/W
0x4800 2468	CONTROL_SDRC_MCFG1	SDRC configuration register 1	R/W

At reset, the following occur:

- CONTROL.[CONTROL_SDRC_SHARING](#)[30:0] copies into SDRC.SDRC_SHARING[30:0].
- CONTROL.[CONTROL_SDRC_MCFG0](#)[30:0] copies into SDRC.SDRC_MCFG_0[30:0].
- CONTROL.[CONTROL_SDRC_MCFG1](#)[30:0] copies into SDRC.SDRC_MCFG_1[30:0].

When LOCK bit SDRC.SDRC_SHARING[30] is set, a copy of SDRC.SDRC_SHARING[30:0] is made into CONTROL.[CONTROL_SDRC_SHARING](#)[30:0].

When LOCK bit SDRC.SDRC_MCFG_0[30] is set, a copy of SDRC.SDRC_MCFG_0[30:0] is made into CONTROL.[CONTROL_SDRC_MCFG0](#)[30:0].

When LOCK bit SDRC.SDRC_MCFG_1[30] is set, a copy of SDRC.SDRC_MCFG_1[30:0] is made into CONTROL.[CONTROL_SDRC_MCFG1](#)[30:0].

13.4.10 Debug and Observability

13.4.10.1 Description

[Figure 13-17](#) is an overview of observability multiplexing, which minimizes the number of signals exchanged at the power domain boundary.

Figure 13-17. Overview of the Debug and Observability Register Functionality

scm-017

Two layers of multiplexer are used to select the set of internal observable signals (PRCM signals, DMA requests, and interrupts) to be routed to the pins dedicated to the hardware debug.

The first layer is in the CORE power domain. It is controlled by the core control module registers and selects the set of internal signals from the CORE power domain to be routed. The second layer is in the WKUP power domain. It is controlled by the wake-up control module registers and selects the set of internal signals from the WKUP power domain.

The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbg0) of the pad. To configure the pads, select mode 5 (0b101) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_CAM_x register (only for hw_dbg0 to hw_dbg11), or select mode 7 (0b111) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_ETK_x register (for all hw_dbg). Before selecting the CORE signals, the WKUPOBSMUX bit field of the CONTROL.CONTROL_WKUP_DEBOBS_n registers must be set to 0.

Table 13-29. Observability Registers

Physical Address	Register Name	Description	Access	
			Device Type	
			E/T/G	S/B
0x4800 2420	CONTROL_DEBOBS_0	Set and configure CORE observable signals 1 and 0.	R/W	R
0x4800 2424	CONTROL_DEBOBS_1	Set and configure CORE observable signals 3 and 2.	R/W	R
0x4800 2428	CONTROL_DEBOBS_2	Set and configure CORE observable signals 5 and 4.	R/W	R

Table 13-29. Observability Registers (continued)

Physical Address	Register Name	Description	Access	
			Device Type	
			E/T/G	S/B
0x4800 242C	CONTROL_DEBOBS_3	Set and configure CORE observable signals 7 and 6.	R/W	R
0x4800 2430	CONTROL_DEBOBS_4	Set and configure CORE observable signals 9 and 8.	R/W	R
0x4800 2434	CONTROL_DEBOBS_5	Set and configure CORE observable signals 11 and 10.	R/W	R
0x4800 2438	CONTROL_DEBOBS_6	Set and configure CORE observable signals 13 and 12.	R/W	R
0x4800 243C	CONTROL_DEBOBS_7	Set and configure CORE observable signals 15 and 14.	R/W	R
0x4800 2440	CONTROL_DEBOBS_8	Set and configure CORE observable signals 17 and 16.	R/W	R
0x4800 2A68	CONTROL_WKUP_DEBOBS_0	Set and configure WKUP observable pins 3, 2, 1, 0.	R/W	R
0x4800 2A6C	CONTROL_WKUP_DEBOBS_1	Set and configure WKUP observable pins 7, 6, 5, 4.	R/W	R
0x4800 2A70	CONTROL_WKUP_DEBOBS_2	Set and configure WKUP observable pins 11, 10, 9, 8.	R/W	R
0x4800 2A74	CONTROL_WKUP_DEBOBS_3	Set and configure WKUP observable pins 15, 14, 13, 12.	R/W	R
0x4800 2A78	CONTROL_WKUP_DEBOBS_4	Set and configure WKUP observable pins 17, 16.	R/W	R

The write capabilities of these registers differ according to the device type.

Perform the following steps to configure observability:

1. To configure the pads properly for hardware debug and observability, select the hardware debug (hw_dbg) function mode 5 in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_CAM_X or mode 7 in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_ETK_X registers.
2. For the observability pads, set the proper values of the WKUPOBSMUX field CONTROL.CONTROL_WKUP_DEBOBS_n. Up to 5 bits are used to select the signal set to be observed (0x00 selection sets the output to CORE_OBSMUXn signal). For more information, see the description of each register in [Section 13.4.10.2, Observability Tables](#).
3. To observe the CORE_OBSMUXn signals from the first layer of the multiplexer, set the WKUPOBSMUX field CONTROL.CONTROL_WKUP_DEBOBS_n to 0x00, and then set the proper values of the OBMUX field CONTROL.CONTROL_DEBOBS_n. A maximum of 7 bits is used to select the signal set to be observed (0b0000000 selection sets the output to 0).

For more information, see the description of each register in [Section 13.4.10.2, Observability Tables](#).

The observability feature of the CONTROL.CONTROL_DEBOBS_n registers can be gated by setting the CONTROL.CONTROL_PROT_CTRL[5] OBSERVABILITYDISABLE bit to 0x1. If the user configures the pads for hardware observability, selected to observe CORE_OBSMUXn signals and set to OBSERVABILITYDISABLE = 0x1, the corresponding hw_dbg outputs are set to 0. Observability of the CORE_OBSMUXn signal is enabled by default (POR value OBSERVABILITYDISABLE = 0x0). Because the type of this bit is read/one-change only (R/OCO), the CORE_OBSMUXn signals can be gated only once after a POR event.

The observability feature of the CONTROL.CONTROL_WKUP_DEBOBS_n registers can be gated using the WKUPOBSERVABILITYDISABLE bit CONTROL.CONTROL_WKUP_DEBOBS_4[31]. If this bit is set, and the pads are configured for hardware observability of the WKUP mux set signals, the corresponding hw_dbg outputs are set to 0. Observability of the WKUP mux set signals is enabled by default (POR value WKUPOBSERVABILITYDISABLE = 0x0).

Because the type of this bit is read/one-change only (R/OCO), the WKUP mux set signals can be gated only once after a POR event.

NOTE: The OBSERVABILITYDISABLE and WKUPOBSERVABILITYDISABLE bits are of the type (R/OCO) to which the following rules apply:

- Write actions that do not change the bit reset value are not considered.
- The first write action that changes the bit reset value is considered, but any subsequent write actions are ignored. No more write actions are effective until the next POR.

NOTE: To disable observability for all hw_dbg I/Os (that is, drive the external observability outputs to 0), observability of the CORE and WKUP domains must be disabled. Disabling only wkup_observability is not sufficient.

13.4.10.2 Observability Tables

This section gives information about all modules and features in the high-tier device. To check the availability of modules and features, see [Section 1.5, AM/DM37x Family](#). Unavailable module and feature pins are not functional.

[Table 13-30](#) through [Table 13-65](#) define the mapped internal signals for each OBSMUX and WKUPOBSMUX value.

Table 13-30. Internal Signals Multiplexed on OBSMUX0

Out Signal Name	Muxed Signal Name	OBSMUX0 Field CONTROL.CONT ROL_DEBOBS_0 [22:16] (dec)	Description	High State	Low State
CORE_OBSMUX0 ⁽¹⁾	tie_low	0	-	-	-

13.4.11 EMI Reduction for Clocking Generation (Spreading)

13.4.11.1 Overview

There are two major forms of digital signals: digital-data and digital-clock (CLK). Digital signals are the principal signal form in today's digital electronic products.

- A digital-data signal can be viewed as a sequence of pulses with different pulse widths
- A clock (CLK) signal is usually a string of rectangular pulses with the same pulse width

In the case of a clock, the generated signal has a predetermined frequency. Electromagnetic radiations such as radio frequency emissions are also generated from the constant frequency clock signals and their harmonics. Unfortunately, a problem exists with some devices such as communication devices for example in that the system clock generates unwanted spurious signals that interfere with the decoding of information from received signals by a receiver of the communication device. Note that data periodicity also causes interference.

This periodicity generates a significant power peak at the selected frequency, which in turn causes an EMI disturbance to the environment.

The harmonics of the generated signal system clock radiates in the other modules of the device, and the spurious energy can be enough to cause enough interference, which results in performance degradation (in the form of high bit error rates in case of a wireless communication interface for example).

To reduce the power peaks (and thus the energy of the electromagnetic noise generated for a specific frequency), an internal frequency modulation of the digital phase-locked loop (DPLL) is used to distribute the energy to many different frequencies, thus reducing the power peaks.

This frequency modulation feature is directly integrated in some DPLLs of the device. The DPLLs that support this additional feature are called DPLL-D in the following.

Figure 13-18 is a diagram of a DPLL that supports the EMI reduction feature.

Figure 13-18. DPLL With EMI Reduction Feature

scm-033

The additional features of the DPLL compliant with EMI reduction are:

- EMI reduction using triangular frequency modulation, also called spread spectrum clocking (SSC).

13.4.11.2 Integration

The DPLLs/domains of the devices that support the EMI reduction feature are:

- DSS DPLL (DSI DPLL)
- CORE domain DPLL (DPLL3)
- PER domain DPLL (DPLL4)
- USBHOST DPLL (DPLL5)

[Figure 13-19](#) shows the integration of DPLL-D in the device.

Figure 13-19. DPLL-D Integration

The control of the DPLL is done by the PRCM module and the SCM:

- The PRCM module controls the clocking generation of the DPLL. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).
- The SCM contains all necessary bits that control the EMI reduction feature (SSC).

13.4.11.2.1 Clocking, Reset, and Power-Management Scheme

See [Chapter 3, Power, Reset, and Clock Management](#).

13.4.11.3 Functional Description

13.4.11.3.1 Spreading Generation Block

[Figure 13-20](#) is a diagram of the spreading generation block. It shows three essential parameters associated with spreading generation:

NOTE: Δf is the deviation from the center frequency. The total spreading deviation is equal to twice Δf .

f_c is the original clock frequency.

f_m is the spreading frequency.

Figure 13-20. Spreading Generation Block Diagram

scm-035

This additional block generates the required waveform used to reduce EMI. This waveform is then modulated with the initial signal to add some controlled deviation in the clock signal frequency, which spreads the energy of the clock and its harmonics into a band of frequencies, and then reduces the electromagnetic interferences.

In any case, the frequency modulation is programmed in the SCM and does not generally need to be changed in real time.

13.4.11.3.2 SSC

13.4.11.3.2.1 Definition

The aim of SSC is to add a variation in the frequency of an original clock, which spreads the generated interferences over a larger band of frequency.

In theory, SSC means that the clock signal is varied around the desired frequency. For example, for a 1-GHz clock, the frequency may be 999.5 MHz at one moment and 1.0005 GHz at another. When SSC is enabled the clock spectrum is spread by the amount of frequency spread. Doing this constantly causes the power of the tone to be spread out more over a broader band of tight frequencies (centered at the desired tone). To realize this constant variation on the original signal, a modulation with an additional signal (called spreading waveform) is realized.

Creating an SSC by spreading the initial clock frequency is done by defining the following parameters:

- The spreading frequency (deviation), which is the ratio of the range of spreading frequency over the original clock frequency
- The modulation rate (f_m), which is used to determine the clock-frequency spreading-cycling rate and is the time during which the generated clock frequency varies through Δf and returns to the original frequency
- The modulation waveform, which describes the variation curve in terms of time

The spectral power reduction in the DPLL clocks is dependent on the modulation index (K), which is a ratio of spreading frequency calculated from the frequency deviation (Δf) and the modulation rate (f_m).

13.4.11.3.2.2 Effect on the Clock Signal

[Figure 13-21](#) is an example of the effect of a triangular spreading on a clock signal.

Figure 13-21. Effect of the SSC in Frequency

[Figure 13-21](#) shows not only the power reduction of the main peak, but also the flatter aspect of the modulated signal. The minimum level of the second signal is higher than the minimum level of the first signal. This effect is normal and is due to the noise added for the modulation.

NOTE: The spreading technique scatters the energy of the peaks on the other frequencies, which reduces the power of the peaks but increases the global noise of the signal.

[Figure 13-22](#) shows the effect of triangular spreading on a clock signal in the time domain.

Figure 13-22. Effect of the SSC in the Time Domain

scm-039

13.4.11.3.2.3 Estimation of the EMI Reduction Level

Figure 13-23 shows the effect of spreading on a clock and its harmonics.

Figure 13-23. Peak Reduction Caused by Spreading

scm-037

The electromagnetic interference reduction can be estimated with the following equation:

$$\text{Peak_power_reduction} = 10 * \log ((\text{Deviation} * f_c) / f_m)$$

With:

- Peak_power_reduction in dB
- Deviation in % of the initial clock frequency (f_c), equals $\Delta f / f_c$
- f_c is the original clock frequency, in MHz
- f_m is the spreading frequency, in MHz

According to equation (1), it is also possible to compute the deviation, and then Δf , for a required peak power reduction:

$$\text{Deviation} = (f_m / f_c) * 10^{(\text{Peak_power_reduction} / 10)}$$

Example:

For $f_c=400$ MHz, deviation =1% peak from f_c ($\Delta f = 4$ MHz) and $f_m=400$ kHz; the estimated peak power reduction is 10dB.

13.4.11.3.2.4 Bandwidth Calculation (Carson Bandwidth Rule)

The Carson bandwidth rule defines the approximate bandwidth requirements of communications system components for a carrier signal that is frequency-modulated by a continuous or broad spectrum of frequencies rather than a single frequency.

The Carson bandwidth rule is expressed by the relation $CBR = 2 * (\Delta f + f_m)$, where CBR is the bandwidth requirement, Δf is the peak frequency deviation, and f_m is the highest frequency in the modulating signal.

For example, an FM signal with a 5-kHz peak deviation and a maximum audio frequency of 3 kHz, would require an approximate bandwidth $2*(5.3) = 16$ kHz.

Theoretically, any FM signal has an infinite number of sidebands and hence an infinite bandwidth, but in practice all significant sideband energy (98% or more) is concentrated within the bandwidth defined by the Carson bandwidth rule.

13.4.11.3.3 SSC Generation Control In The Device

SSC is performed by changing the feedback divider (M) in a triangular pattern. Implying, the frequency of the output clock would vary in a triangular pattern. The frequency of this pattern would be modulation frequency (f_m). The peak (ΔM) or the amplitude of the triangular pattern as a percent of M would be equal to the percent of the output frequency spread (Δf); that is, $\Delta M / M = \Delta f / f_c$.

Next, mark with F_{inp} the frequency of the clock signal at the input of the DPLL. Because it is divided to $N + 1$ before entering the phase detector, the internal reference frequency is $F_{ref} = F_{inp} / (N + 1)$.

Assume the central frequency f_c to be equal to the DPLL output frequency F_{out} , or $f_c = F_{out} = (F_{inp} / (N + 1)) * (M / M_2)$.

The positions of the dividers N, M and M2 in the above formula can be also explained from the [Figure 13-18](#).

Because this is in band modulation for the DPLL, the modulation frequency is required to be within the loop bandwidth (lowest BW of $F_{ref} / 70$) of the DPLL. A higher modulation frequency results in lesser spreading in the output clock. SSC can be enabled by asserting the bit and can be disabled using the same bit. For a certain ADPLL generating clock within domain – X , the spread spectrum generation is enabled from SCM by setting the CONTROL.CONTROL_X_DPLL_SPREADING[4] R_X_SPREADING_ENABLE bit. When this bit is deasserted, SSC is disabled only after completion of one full cycle of the triangular pattern given by the modulation frequency. This is done to maintain the average frequency.

Modulation frequency (f_m) can be programmed as a ratio of $F_{ref} / 4$; that is, the value that needs to be programmed $\text{ModFreqDivider} = F_{ref} / (4^*f_m)$. The ModFreqDivider is split into Mantissa and 2^Exponent ($\text{ModFreqDivider} = \text{ModFreqDividerMantissa} * 2^{\text{ModFreqDividerExponent}}$). The mantissa is controlled by 7-bit signal $\text{ModFreqDividerMantissa}$ through the CONTROL.CONTROL_X_DPLL_SPREADING_FREQ[6:0] R_X_MOD_FREQ_MANT bit field. The exponent is controlled by 3-bit signal $\text{ModFreqDividerExponent}$ through the CONTROL.CONTROL_X_DPLL_SPREADING_FREQ[9:7] R_X_MOD_FREQ_EXP bit field.

NOTE: Although the same value of ModFreqDivider can be obtained by different combinations of mantissa and exponent values, it is recommended to get the target ModFreqDivider by programming the maximum mantissa and a minimum exponent.

To define the Frequency spread (Δf), ΔM must be controlled as explained previously. To define ΔM , the step size of M for each Fref during the triangular pattern must be programmed; that is, $\Delta M = \text{ModFreqDivider} * \text{DeltaMStep}$. DeltaMStep is split into integer part and fractional part. Integer part is controlled by 2-bit signal DeltaMStepInteger through the CONTROL.CONTROL_X_DPLL_SPREADING_FREQ[29:28] R_DSS_DELTA_M_INT bit field. Fractional part is controlled by 18-bit signal DeltaMStepFraction through the CONTROL.CONTROL_X_DPLL_SPREADING_FREQ[27:10] R_DSS_DELTA_M_FRACT bit field.

The frequency spread achieved has an overshoot of 20 percent or an inaccuracy of +20 percent.

If the Q_X_SPREADING_SIDE bit CONTROL.CONTROL_X_DPLL_SPREADING[8] is set to 1, the frequency spread on lower side is twice the programmed value. The frequency spread on higher side is 0 (except for the overshoot as described previously).

As in the fractionalIM case, there is restriction of range of M values here. The restriction is $M - \Delta M \geq 20$. Also, $M + \Delta M \leq 2045$. In case the downspread feature is enabled, $M - 2 * \Delta M \geq 20$ and $M \leq 2045$.

13.4.11.4 Basic Programming Model

13.4.11.4.1 SSC Configuration

The configuration of the spreading feature is not mandatory when programming the DPLL. This feature is usually enabled when the DPLL clocks generate harmonics that can potentially interfere with the GSM carrier frequencies.

Let's take the SSC featured ADPLL in the CORE domain and try to set the output frequency to $F_{out} = f_c = 160$ MHz. The frequency of the input clock source for CORE ADPLL is $F_{inp} = 38.4$ MHz.

1. The desired output frequency can be achieved with the following ratio of the divider coefficients: $(M / M2)^{*}1/(N+1) = F_{out} / F_{inp} = 160 / 38.4 = 25 / 6$. The dividers used in the CORE ADPLL can be set within the following ranges: $N = 0..127$; $M = 0..2047$; $M2 = 1;2$. The desired output frequency is achieved through the following choice of possible divider values: $M = 25$; $N = 2$ and $M2 = 2$. In that case the reference clock $F_{ref} = F_{inp} / (N+1) = 38.4 / 3 = 12.8$ MHz.

The feedback divider value $M = 25$ is chosen to satisfy the restriction from [Section 13.4.11.3.3](#). If, for example, the deviation $\Delta M / M = \Delta f / F_c = 0.01$ (1%) is chosen, we have $M < 2045 / 1.01$ and at the same time $M > 20 / 0.99 = 20.2$.

Once the clock generation control registers are configured, it is possible to configure the spreading on the clock signal.

2. Calculate the ratio between central(output) frequency and modulation frequency on the base of the desired peak power reduction, PPR and chosen relative deviation $\Delta f / F_{out}$, where $\Delta f / F_{out} = f_m / f_c * 10^8$ (PPR/10). To achieve $PPR = 10$ dB with SSC deviation chosen to be equal to 1 percent, the ratio $f_m / f_c = 0.001$ is needed; hence, $f_m = 0.001 * f_c = 0.001 * 160$ MHz = 160 KHz. To check whether the modulation frequency has the appropriate value, check whether it is within the DPLL loop bandwidth or if $f_m < F_{ref} / 70 = 12.8 / 70 = 182.86$ KHz, which is true.
3. Calculate the contents of the CONTROL.CONTROL_X_DPLL_SPREADING_FREQ[6:0] R_X_MOD_FREQ_MANT and CONTROL.CONTROL_X_DPLL_SPREADING_FREQ[9:7] R_X_MOD_FREQ_EXP bit fields on the base of ModFreqDivider value: $ModFreqDivider = F_{ref} / (4*f_m) = 12.8 / 4 * 0.16 = 20 = 20 * 2^{10}$. This means we should write R_X_MOD_FREQ_EXP=0x0 and R_X_MOD_FREQ_INT=0x14.
4. The DeltaMStep parameter is calculated according to the formula:

$$\text{DeltaM} = \Delta M / \text{ModFreqDivider}$$

 On the other side $\Delta M = M * (\Delta f / f_c)$, hence, parameter $\text{DeltaM} = M * (\Delta f / f_c) / \text{ModFreqDivider} = 0.01 * 25 / 20 = 0.0125$.
 In this case write 0x0 in CONTROL.CONTROL_X_DPLL_SPREADING_FREQ[29:28] R_DSS_DELTA_M_INT bit field. To express the fractional part 0.0125 as a binary, calculate: $0.0125 * 2^{18} = 3276.8$, then round to 3277, convert the integer part to binary and write it into the field:

$$\text{CONTROL.CONTROL_X_DPLL_SPREADING_FREQ[27:10]} \text{ R_DSS_DELTA_M_FRACT} = 0b000000110011001101$$
5. The spreading must be enabled using the CONTROL.CONTROL_X_DPLL_SPREADING[4] R_X_SPREADING_ENABLE bit.
