NOTE: It is necessary to configure the spreading on a clock carefully to avoid adding noise on frequencies that are used by another module. For example, adding spreading on a clock to reduce noise on GSM frequencies can "move" the generated noise to the frequency of the memory controller and degrade its performance.

The state of the modulation feature can be monitored with the R_X_SPREADING_ENABLE_STATUS bit of the corresponding register.

13.5 SCM Programming Model

13.5.1 Feature Settings

NOTE: The settings listed in the following sections are example patterns for configuring the signal group I/O parameters of I²C, SDRC, GPMC, McBSP2, and McSPI1:

- [Section 13.5.1.10, I²C I/O Internal Pullup Enable](#)
- [Section 13.5.1.11, SDRC I/O Drive Strength Selection](#)
- [Section 13.5.1.12, GPMC I/O Far End Load Settings](#)
- [Section 13.5.1.13, McBSP2 I/O Far End Load Settings](#) and
- [Section 13.5.1.14, McSPI1 I/O Far End Load Settings](#)

For more information about the settings for all interface signal groups, see [Section 13.4.7.6, Signal Integrity Parameter Control Registers With Pad Group Assignment](#).

13.5.1.1 Force Pad Configuration MuxMode by High-Speed USB

The two pads hsusb0_data0 and hsusb0_data1 can force pad configuration MuxMode when the CARKITEN signal is generated:

- CONTROL.[CONTROL_DEVCONF1\[19\]](#) CARKITHSUSB0DATA0AUTOEN bit:
 - 0: The hsusb0_data0 MuxMode signal is driven by the CONTROL.CONTROL_PADCONF_HSUSBO_NXT[18:16] MUXMODE1 bit.
 - 1: The hsusb0_data0 MuxMode signal is forced to 0x2 when the CARKITEN signal is active.
- CONTROL.[CONTROL_DEVCONF1\[20\]](#) CARKITHSUSB0DATA1AUTOEN bit:
 - 0: The hsusb0_data1 MuxMode signal is driven by the CONTROL.CONTROL_PADCONF_HSUSBO_DATA1[2:0] MUXMODE0 bit.
 - 1: The hsusb0_data1 MuxMode signal is forced to 0x2 when the CARKITEN signal is active.

NOTE: Associated pad configuration registers remain unchanged.

For more information about high-speed USB, see [Chapter 22, High-Speed USB Controllers](#).

13.5.1.2 Video Driver

This section gives information about all modules and features in the high-tier device. To check the availability of modules and features, see [Section 1.5, AM/DM37x Family](#). Unavailable module and feature pins are not functional.

- CONTROL.[CONTROL_DEVCONF1\[18\]](#) TVOUTBYPASS bit:
 - 0b0: Dual 10-bit video DAC TV out bypass disable
 - 0b1: Dual 10-bit video DAC TV out bypass enable
- CONTROL.[CONTROL_DEVCONF1\[11\]](#) TVACEN bit:
 - 0b0: Enables dc coupling for TV output
 - 0b1: Enables ac coupling for TV output

For more information about video DACs, see [Chapter 7, Display Subsystem](#).

13.5.1.3 McBSP1 Internal Clock

The McBSP1 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP1.

- CONTROL.[CONTROL_DEVCONF0\[4\]](#) MCBSP1_FSR bit:
 - 0: FSR is from the pin mcbsp1_fsr.
 - 1: FSR is from the pin mcbsp1_fsx.

- CONTROL.[CONTROL_DEVCONF0\[3\]](#) MCBSP1_CLKR bit:
 0: CLKR is from the pin mcbsp1_clk.
 1: CLKR is from the pin mcbsp1_clkx.
- CONTROL.[CONTROL_DEVCONF0\[2\]](#) MCBSP1_CLKS bit:
 0: CLKS is from the PRCM functional clock.
 1: CLKS is from the pin mcbsp_clks.

For more details on McBSP, see [Chapter 21, McBSP](#).

13.5.1.4 McBSP2 Internal Clock

The McBSP2 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP2. The McBSP2 does not have mcbsp2_clk and mcbsp2_fsr external pins. Clock input is from the mcbsp2_clkx pin; FSR input is from the mcbsp2_fsx pin.

- CONTROL.[CONTROL_DEVCONF0\[6\]](#) MCBSP2_CLKS bit:
 0: Clock is from the PRCM functional clock.
 1: Clock is from the external pin mcbsp_clks.

For more information about McBSP, see [Chapter 21, McBSP](#).

13.5.1.5 McBSP3 Internal Clock

The McBSP3 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP3. The McBSP3 does not have mcbsp3_clk and mcbsp3_fsr external pins. Clock input is from the mcbsp3_clkx pin; FSR input is from the mcbsp3_fsx pin.

- CONTROL.[CONTROL_DEVCONF1\[0\]](#) MCBSP3_CLKS bit:
 0: Clock is from the PRCM functional clock.
 1: Clock is from the external pin mcbsp_clks.

For more information about McBSP, see [Chapter 21, McBSP](#).

13.5.1.6 McBSP4 Internal Clock

The McBSP4 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP4. The McBSP4 does not have mcbsp4_clk and mcbsp4_fsr external pins. Clock input is from the mcbsp4_clkx pin; FSR input is from the mcbsp4_fsx pin.

- CONTROL.[CONTROL_DEVCONF1\[2\]](#) MCBSP4_CLKS bit:
 0: Clock is from the PRCM functional clock.
 1: Clock is from the external pin mcbsp_clks.

For more information about McBSP, see [Chapter 21, McBSP](#).

13.5.1.7 McBSP5 Internal Clock

The McBSP5 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP5. The McBSP5 does not have mcbsp5_clk and mcbsp5_fsr external pins. Clock input is from the mcbsp5_clkx pin; FSR input is from the mcbsp5_fsx pin.

- CONTROL.[CONTROL_DEVCONF1\[4\]](#) MCBSP5_CLKS bit:
 0: Clock is from the PRCM functional clock.
 1: Clock is from the external pin mcbsp_clks.

For more information about McBSP, see [Chapter 21, McBSP](#).

13.5.1.8 MMC/SD/SDIO2 Module Input Clock Selection

- CONTROL.[CONTROL_DEVCONF1\[6\]](#) MMCSdio2ADPCLKISEL bit:
 0: Input clock is from the external pin.

1: Internal loopback, module input clock is copied from the module output clock.

13.5.1.9 Setting Sensitivity on sys_ndmreq[3:0] Input Pins

The four sys_ndmreq0 to sys_ndmreq3 input pins can be either level or edge sensitive.

- CONTROL.[CONTROL_DEVCONF0\[0\]](#) SENSDMREQ0 bit:
 - 0: Level sensitivity
 - 1: Edge sensitivity
- CONTROL.[CONTROL_DEVCONF0\[1\]](#) SENSDMREQ1 bit:
 - 0: Level sensitivity
 - 1: Edge sensitivity
- CONTROL.[CONTROL_DEVCONF1\[7\]](#) SENSDMREQ2 bit:
 - 0: Level sensitivity
 - 1: Edge sensitivity
- CONTROL.[CONTROL_DEVCONF1\[8\]](#) SENSDMREQ3 bit.
 - 0: Level sensitivity
 - 1: Edge sensitivity

For more information about DMA, see [Chapter 11, DMA](#).

13.5.1.10 I²C I/O Internal Pullup Enable

The I/O internal pullups of I2C1, I2C2, I2C3, and I2C4 can be enabled:

- CONTROL.[CONTROL_PROG_IO1\[19\]](#) PRG_I2C1_PULLUPRESX bit:
 - 0: I2C1 I/O internal pullup enabled
 - 1: I2C1 I/O internal pullup disabled
- CONTROL.[CONTROL_PROG_IO1\[0\]](#) PRG_I2C2_PULLUPRESX bit:
 - 0: I2C2 I/O internal pullup enabled
 - 1: I2C2 I/O internal pullup disabled
- CONTROL.[CONTROL_PROG_IO2\[7\]](#) PRG_I2C3_PULLUPRESX bit:
 - 0: I2C3 I/O internal pullup enabled
 - 1: I2C3 I/O internal pullup disabled
- CONTROL.[CONTROL_PROG_IO_WKUP1\[5\]](#) PRG_SR_PULLUPRESX bit:
 - 0: I2C4 I/O internal pullup enabled
 - 1: I2C4 I/O internal pullup disabled

NOTE: This feature is used for the I²C master operating mode.

For more information about I²C, see [Chapter 17, Multimaster Highspeed I²C Controller](#).

13.5.1.11 SDRC I/O Drive Strength Selection

- The CONTROL.[CONTROL_PROG_IO0\[31\]](#) SDRC_LOWDATA bit selects data[15:0] DQS0, DQS1, DM0, and DM1 I/O drive strength:
 - 0: Load range = [2 pF – 4 pF]
 - 1: Load range = [4 pF – 12 pF]
- The CONTROL.[CONTROL_PROG_IO0\[30\]](#) SDRC_HIGHDATA bit selects data[31:16] DQS2, DQS3, DM2, and DM3 I/O drive strength:
 - 0: Load range = [2 pF – 4 pF]
 - 1: Load range = [4 pF – 12 pF]

- The CONTROL.[CONTROL_PROG_IO0\[29\]](#) SDRC_ADDRCTR bit selects the I/O drive strength of the NRAS, NCAS, NWE, NCLK, CLK, BA0, and BA1 signals:
 - 0: Load range = [2 pF – 4 pF]
 - 1: Load range = [4 pF – 12 pF]
- The CONTROL.[CONTROL_PROG_IO0\[28\]](#) SDRC_NCS0 bit selects the NCS0 and CKE0 I/O drive strength:
 - 0: Load range = [2 pF – 4 pF]
 - 1: Load range = [4 pF – 12 pF]
- The CONTROL.[CONTROL_PROG_IO0\[27\]](#) SDRC_NCS1 bit selects the NCS1 and CKE1 I/O drive strength:
 - 0: Load range = [2 pF – 4 pF]
 - 1: Load range = [4 pF – 12 pF]

13.5.1.12 GPMC I/O Far End Load Settings

- The CONTROL.[CONTROL_PROG_IO0\[26\]](#) PRG_GPMC_A1_LB bit selects GPMC_A1 I/O equivalent far end load within:
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.[CONTROL_PROG_IO0\[25\]](#) PRG_GPMC_A2_LB bit selects GPMC_A2 I/O equivalent far end load within:
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.[CONTROL_PROG_IO0\[24\]](#) PRG_GPMC_A3_LB bit selects GPMC_A3 I/O equivalent far end load within:
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.[CONTROL_PROG_IO0\[23\]](#) PRG_GPMC_A4_LB bit selects GPMC_A4 I/O equivalent far end load within:
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.[CONTROL_PROG_IO0\[22\]](#) PRG_GPMC_A5_LB bit selects GPMC_A5 I/O equivalent far end load within:
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.[CONTROL_PROG_IO0\[21\]](#) PRG_GPMC_A6_LB bit selects GPMC_A6 I/O equivalent far end load within:
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.[CONTROL_PROG_IO0\[20\]](#) PRG_GPMC_A7_LB bit selects GPMC_A7 I/O equivalent far end load within:
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.[CONTROL_PROG_IO0\[19\]](#) PRG_GPMC_A8_LB bit selects GPMC_A8 I/O equivalent far end load within:
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.[CONTROL_PROG_IO0\[18\]](#) PRG_GPMC_A9_LB bit selects GPMC_A9 I/O equivalent far end load within:
 - 0: Load range = [1 pF – 10 pF]

- 1: Load range = [10 pF – 16 pF]
- The CONTROL.**CONTROL_PROG_IO0[17]** PRG_GPMC_A10_LB bit selects GPMC_A10 I/O equivalent far end load within::
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.**CONTROL_PROG_IO0[16]** PRG_GPMC_A11_LB bit selects GPMC_A11 I/O equivalent far end load within::
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.**CONTROL_PROG_IO0[15]** PRG_GPMC_MIN_CFG_LB bit selects data[7:0], WAIT0, NADV_ALE , NOE, NWE I/O equivalent far end load within::
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.**CONTROL_PROG_IO0[14]** PRG_GPMC_D8_D15_LB bit selects data[15:8] I/O equivalent far end load within::
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.**CONTROL_PROG_IO0[13]** PRG_GPMC_NCS0_LB bit selects GPMC_NCS0 I/O equivalent far end load within::
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.**CONTROL_PROG_IO0[12]** PRG_GPMC_NCS1_LB bit selects GPMC_NCS1 I/O equivalent far end load within::
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.**CONTROL_PROG_IO0[11]** PRG_GPMC_NCS2_LB bit selects GPMC_NCS2 I/O equivalent far end load within::
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.**CONTROL_PROG_IO0[10]** PRG_GPMC_NCS3_LB bit selects GPMC_NCS3 I/O equivalent far end load within::
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.**CONTROL_PROG_IO0[9]** PRG_GPMC_NCS4_LB bit selects GPMC_NCS4 I/O equivalent far end load within::
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.**CONTROL_PROG_IO0[8]** PRG_GPMC_NCS5_LB bit selects GPMC_NCS5 I/O equivalent far end load within::
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.**CONTROL_PROG_IO0[7]** PRG_GPMC_NCS6_LB bit selects GPMC_NCS6 I/O equivalent far end load within::
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL.**CONTROL_PROG_IO0[6]** PRG_GPMC_NCS7_LB bit selects GPMC_NCS7 I/O equivalent far end load within::
 - 0: Load range = [1 pF – 10 pF]

- 1: Load range = [10 pF – 16 pF]
- The CONTROL_CONTROL_PROG_IO0[5] PRG_GPMC_CLK_LB bit selects GPMC_CLK I/O equivalent far end load within:-
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL_CONTROL_PROG_IO0[4] PRG_GPMC_NBE0_CLE_LB bit selects GPMC_NBE0_CLE I/O equivalent far end load within:-
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL_CONTROL_PROG_IO0[3] PRG_GPMC_NBE1_LB bit selects GPMC_NBE1 I/O equivalent far end load within:-
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL_CONTROL_PROG_IO0[2] PRG_GPMC_NWP_LB bit selects GPMC_NWP I/O equivalent far end load within:-
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL_CONTROL_PROG_IO1[31] PRG_GPMC_WAIT1_LB bit selects GPMC_WAIT1 I/O equivalent far end load within:-
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL_CONTROL_PROG_IO1[30] PRG_GPMC_WAIT2_LB bit selects GPMC_WAIT2 I/O equivalent far end load within:-
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL_CONTROL_PROG_IO1[29] PRG_GPMC_WAIT3_LB bit selects GPMC_WAIT3 I/O equivalent far end load within:-
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]

13.5.1.13 MCBSP2 I/O Far End Load Settings

- The CONTROL_CONTROL_PROG_IO2[31] PRG_MCBSP2_LB bit selects the FSX, CLKX, DR, and DX I/O equivalent far end load within:-
 - 0: Load range = [1 pF–10 pF]
 - 1: Load range = [10 pF–16 pF]

13.5.1.14 MCSPI1 I/O Far End Load Settings

- The CONTROL_CONTROL_PROG_IO2[1] PRG_MCSPI1_MIN_CFG_LB bit selects CLK, SOMI, SIMO and CS0 I/O equivalent far end load within:-
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL_CONTROL_PROG_IO2[0] PRG_MCSPI1_CS1_LB bit selects CS1 I/O equivalent far end load within:-
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]
- The CONTROL_CONTROL_PROG_IO1[4] PRG_MCSPI1_CS2_LB bit selects CS2 I/O equivalent far end load within:-
 - 0: Load range = [1 pF – 10 pF]
 - 1: Load range = [10 pF – 16 pF]

- The CONTROL.[CONTROL_PROG_IO1](#)[3] PRG_MCSPI1_CS3_LB bit selects CS3 I/O equivalent far end load within:
 - 0: Load range = [1 pF–10 pF]
 - 1: Load range = [10 pF–16 pF]

13.5.1.15 Force MPU Writes to Be Nonposted

The MPUFORCEWRNP bit CONTROL.[CONTROL_DEVCONF1](#)[9] bit is for debugging only. When this bit is set to 1 (for debugging), all writes are forced to nonposted and the cache attributes are ignored. By default, this bit should be set to 0 (posted writes). For the best performance, keep this bit at 0.

13.5.2 Extended-Drain I/Os and PBIAS Cells Programming Guide

NOTE: The device can be supplied by an external power IC. TI provides such a global solution to its customers with the power IC.

If the device is associated with the power IC, before using an extended-drain I/O interface, the software must program the power IC to enable the VMMC1 (for the MMC/SD/SDIO1 module or muxed GPIO I/Os) or VIO for (gpio126, gpio127, and gpio129 I/Os), and the LDO and to provide a 1.8-V/3.0-V voltage. This is done by software through the inter-integrated circuit (I²C™) interface that links the device and power IC.

If the application does not want the interface running at 3.0 V, software users must then assert the VMODE signal to low for 1.8-V activity: in this case, the PBIAS is connected to ground. (See [Figure 13-24](#).)

[Table 13-66](#) lists the control signal with the corresponding control bits from the CONTROL.[CONTROL_PBIAS_LITE](#), CONTROL.[CONTROL_PROG_IO1](#) and CONTROL.[CONTROL_WKUP_CTRL](#) registers to configure the PBIAS and the extended-drain I/O cells. These signals can be software-controlled.

Table 13-66. Control Signals

Control Signal	Bit for MMC/SD/SDIO1 Module Using PBIAS0 Cell	Bit for GPIO I/Os Using PBIAS1 Cell	Reset Value
PWRDNZ	CONTROL. CONTROL_PBIAS_LITE [1] PBIASLITEPWRDNZ0	CONTROL. CONTROL_PBIAS_LITE [9]PBIASLIT EPWRDNZ1;	0
		CONTROL. CONTROL_WKUP_CTRL [6]GPIO_IO _PWRDNZ	
VMODE	CONTROL. CONTROL_PBIAS_LITE [0] PBIASLITEVMODE0	CONTROL. CONTROL_PBIAS_LITE [8] PBIASLITEVMODE1	1
SUPPLY_HIGH	CONTROL. CONTROL_PBIAS_LITE [7] PBIASLITESUPPLYHIGH0	CONTROL. CONTROL_PBIAS_LITE [15] PBIASLITESUPPLYHIGH1	0
SPEEDCTRL	CONTROL. CONTROL_PROG_IO1 [20] PRG_SDMMC1_SPEEDCTRL	N/A	0
VMODEERROR	CONTROL. CONTROL_PBIAS_LITE [3] PBIASLITEVMODEERROR0 bit	CONTROL. CONTROL_PBIAS_LITE [11] PBIASLITEVMODEERROR1	0

The two PBIAS cells support two ranges of I/O power supply: 1.8 V, typical for low-voltage applications, and 3.0 V, typical for high-voltage applications. For each supply voltage range, the cell generates suitable bias voltage (PBIAS) for extended-drain PMOS devices.

NOTE: If SDMMC1_VDDS (or SIM_VDDS) is supplied before the device reset is released, the voltage must be 3 V. It is not recommended to supply the vdds_mmc1 (or vdds_sim) pad with 1.8 V unless software has configured the PBIAS cells accordingly.

CAUTION

A PBIAS cell must be programmed according to peripheral power supply voltage. See [Table 13-67](#).

Table 13-67. Voltage Configuration⁽¹⁾

PBIASLITEVMODE Configuration	SDMMC1_VDDS/SIM_VDDS Voltage	Reset Value
1.8 V	1.8 V	Normal 1.8-V operation
1.8 V	3.0 V	Damaging configuration ⁽²⁾
3.0 V	1.8 V	Degraded functionality ⁽²⁾
3.0 V	3.0 V	Normal 3.0-V operation

⁽¹⁾ For damaging configuration, hardware system protection is provided to prevent deterioration of the associated extended-drain I/Os.

⁽²⁾ It is forbidden to use these modes.

[Figure 13-24](#) describes the programming flow to go from 3.0 V to 1.8 V, and vice versa.

Figure 13-24. Flow Chart

scm-019

The PBIAS output is the same as SDMMC1_VDDS/SIM_VDDS when the corresponding PBIAS cell related PWRDNZ bit is LOW. Once the SDMMC1_VDDS/SIM_VDDS supply settles, software releases the PWRNDZ (pulls it HIGH). This then starts up the PBIAS cell work to generate the PBIAS voltage. During the complete process the corresponding I/Os cannot be used to transmit data.

NOTE: In the case of a damaging configuration, hardware system protection prevents deterioration of the associated extended-drain I/Os.

CAUTION

The following are critical requirements for the cell:

- The VMODE bit must be defined before the PWRNDZ bit is made HIGH (cell is brought out of PWRNDZ).
- The default state of VMODE bit must be HIGH (to indicate 3.0-V operation).
- PWRNDZ bit must be kept LOW when the SDMMC1_VDDS/SIM_VDDS supply is ramping up (PWRNDZ bit is not required to be kept LOW during ramp down of the supply). This could be damaging.

CAUTION

It is strongly recommended to synchronize any changes of the PBIASLITEPWRDNZ1 and GPIO_IO_PWRDNZ bits (that is, both bits must be set to 1 or 0 at the same time).

The following power-saving recommendations apply to the power-down mode control PWRDNZx (the PBIASLITEPWRDNZ0/PBIASLITEPWRDNZ1 and GPIO_IO_PWRDNZ bits) and the pad configuration settings for different SDMMC1/GPIO pad setups:

- When SDMMC1 (or GPIO) I/Os are used with SDMMC1 (or GPIO) functionality and vdds_sdmmc1 (or vdds_sim) = vdds = 1.8 V, the corresponding PWRDNZx bit(s) must be set to 1 when the vdds_sdmmc1 (or vdds_sim) power supply voltage is stabilized.
- When SDMMC1 (or GPIO) I/Os are not connected and vdds_sdmmc1 (or vdds_sim) = 0 V, the corresponding PWRDNZx bit(s) must be set to 0.
- When SDMMC1 (or GPIO) I/Os are not connected and vdds_sdmmc1 (or vdds_sim) = 1.8 V, one of the following settings can be done to reduce leakage:
 - The corresponding PWRDNZx bit(s) is kept at 0.
 - If the corresponding PWRDNZx bit(s) is 1, the INPUTENABLE bit must be maintained at 0 in the corresponding CONTROL_PADCONF_x register. In this case, the receiver buffer does not cause static current, even if the pad is left floating. Weak pullup/pulldown resistors can be used to define the pad state, if needed. The setting of the weak pull resistor does not affect the I/O leakage in this case.
 - If the corresponding PWRDNZx bit(s) must be kept at 1 and INPUTENABLE = 1, the level of the pad signal must be defined using weak pullup/pulldown resistors at the pad, in the event of a floating pad. If weak pull resistors are not defined and the pad is floating, the current, drawn from VDDS, can be high because of the static current in the receiver.

For more information about power-saving strategies related to pad configuration, see [Section 13.5.4, Pad Configuration Programming Points](#).

13.5.2.1 PBIAS Error Generation

Table 13-68 summarizes the generation of the PBIAS error interrupt (PBIAS0_ERROR and PBIAS1_ERROR) depending on the various CONTROL.[CONTROL_PBIAS_LITE](#) bits control. The shaded row is a potential condition that could cause a reliability issue if not detected. To prevent this reliability issue, the PBIAS voltage is kept at SDMMC1_VDDS/SIM_VDDS level when the PBIAS error signal is HIGH.

Table 13-68. PBIAS Error Signal Truth Table

VMODE	PWRDNZ	SUPPLY_HIGH	PBIAS ERROR
X	X	X	0
0	0	X	0
0	1	0	0
0	1	1	1
X	1	X	1
1	0	X	0
1	1	0	1
1	1	1	0

NOTE: PBIAS ERROR = 1: VMODE level not same as SUPPLY_HIGH

PBIAS ERROR = 0: VMODE level same or VMODE not considered

The PBIAS errors, PBIAS0_ERROR and PBIAS_ERROR1, are merged and connected to the MPU subsystem interrupt controller.

The CONTROL.[CONTROL_PBIAS_LITE](#)[i] PBIASLITEVMODEERROR (where i = 3 or 11) bits also indicate if this kind of error occurs.

13.5.2.2 Critical Timing Requirements

It is crucial that the PBIAS and I/O cell related PWRDNZ bits are deasserted (made 1 from 0) only after SDMMC1_VDDS/SIM_VDDS is stable. The device supports only the power-up sequence in which VDD2 ramps up before VDDS. However, SDMMC1_VDDS/SIM_VDDS must come up after both VDD2 and VDDS.

Figure 13-25 show the expected behavior of PWRDNZ bit with regard to supply ramp up. This figure also shows the only possible combination when VDDS ramps up before VDD2.

Figure 13-25. VDDS Ramps Up Before VDD2

NOTE: These timing requirements are applicable only when SDMMC1_VDDS/SIM_VDDS is 3.0 V. If SDMMC1_VDDS/SIM_VDDS is 1.8 V, VDDS and SDMMC1_VDDS/SIM_VDDS can be ramped up simultaneously.

13.5.2.3 Speed Control and Voltage Supply State

There are other control bits, PRG_SDMMC1_SPEEDCTRL in the CONTROL.[CONTROL_PROG_IO1](#) and SUPPLYHIGH in the CONTROL.[CONTROL_PBIAS_LITE](#) registers:

- PRG_SDMMC1_SPEEDCTRL bit can be used to reduce dynamic current if fast rise/fall times are not needed.
- SUPPLYHIGH bit signal is used to inform the cell on the value of SDMMC1_VDDS/SIM_VDDS signal (0b0 = 1.8 V and 0b1 = 3.0 V).

13.5.3 Off Mode Preliminary Settings

The following actions must be performed once, and remain valid for all device OFF <-> ON transitions:

- Program a valid device OFF pads configuration, by setting in each CONTROL. **CONTROL_PADCONF_X** register all off mode values bits: OFFPULLTYPESELECT (OFF mode pull type), OFFPULLUDENABLE (OFF mode pull enabling), OFFOUTVALUE (OFF mode output value), OFFOUTENABLE (OFF mode output enabling), and OFFENABLE (OFF mode pad state override control) .
- Program a valid device ACTIVE pads configuration by setting pertinent bits in each CONTROL. **CONTROL_PADCONF_X** register (see [Section 13.5.4, Pad Configuration Programming Points](#)).
- Perform a device ACTIVE pads configuration saving in the save and restore memory from the wake-up control module by asserting the STARTSAVE bit CONTROL.**CONTROL_PADCONF_OFF[1]**.
- Set the SCM in smart idle mode by setting the IDLEMODE bit field CONTROL.**CONTROL_SYSCONFIG[4:3]** (this ensures that its clocks cannot be cut until the save procedure is complete).
- Enable/disable the wake-up event detection capability of the pads by setting the WAKEUPENABLE bit CONTROL. **CONTROL_PADCONF_X**.

NOTE: When the wake-up detection is enabled for a pad, this pad is configured as input. Therefore, do not forget to write 0b1 in the OFFOUTENABLE bit CONTROL. **CONTROL_PADCONF_X** to disable the output capability.

For further information, see [Chapter 3, Power, Reset, and Clock Management](#).

13.5.4 Pad Configuration Programming Points

To configure the pad, ensure that the following are done:

- Identify signals required on the interface based on the target application.
Example: To configure the UART1 interface on balls, the required signals are uart1_tx, uart1_rts, uart1_cts, and uart1_rx.
- Choose the pads used for those signals. Some signals could be available on several pads and/or may be multiplexed with other signals needed for another application. See [Section 13.4.4.3, Pad Multiplexing Register Fields](#).

Example: Each UART1 interface signal is available on two pads. These signals are also multiplexed with a McBSP signal.

Assume that the McBSP interface is required in the system. Therefore, for the UART1 interface signals, pads must be used where those signals are not multiplexed with the McBSP signal.

- Identify the pad configuration registers associated with the pads to be used in the application. See [Section 13.4.4.3, Pad Multiplexing Register Fields](#).

Example: Under the previous hypothesis, the pad configuration registers to program are:

- uart1_cts: CONTROL.CONTROL_PADCONF_DSS_DATA0[15:0]
- uart1_rts: CONTROL.CONTROL_PADCONF_DSS_DATA0[31:16]
- uart1_tx: CONTROL.CONTROL_PADCONF_DSS_DATA6[15:0]
- uart1_rx: CONTROL.CONTROL_PADCONF_DSS_DATA6[31:16]

NOTE: In this configuration, dss_datan (where n = 0) signals are not available on these balls.

- Configure the MUXMODE field of each pad configuration register (CONTROL).

[CONTROL_PADCONF_X](#)) associated with the pads used. [Section 13.4.4.3, Pad Multiplexing Register Fields](#), lists the entire mode available for each pin. Write the binary value of the mode used in the MUXMODE field of the pad configuration registers.

Example: UART1 signals are available in mode 2. Therefore, write 0b010 in the corresponding MUXMODE field of the pad configurations registers to be programmed.

- Configure the pull of the pad when used as input. When the pad is used as output, the pull is automatically disabled. [Section 13.4.4.3, Pad Multiplexing Register Fields](#), lists the pull available on each pad and its reset value. Set the appropriate value for the PULLTYPESELECT bit of the pad configuration register to set the pull value (0b0 = Pull Down selected, 0b1 = Pull Up selected) and set the PULLUDENABLE bit of the pad configuration register to enable the pull on the pad (0b0 = pull disabled, 0b1 = pull enabled)

Example: uart1_rts and uart1_tx are output signals; therefore, the pull is automatically disabled on the pad. Because uart1_cts and uart1_rx are input signals, configure the pull for these pads:

- uart1_cts: Enable pullup (write 0b1 in the PULLTYPESELECT bit and 0b1 in the PULLUDENABLE bit of the corresponding pad configuration register)
- uart1_rx: Enable pullup (write 0b1 in the PULLTYPESELECT bit and 0b1 in the PULLUDENABLE bit of the corresponding pad configuration register)
- Set the INPUTENABLE bit of the pad configuration register if the pin is used as input.

Example: uart1_rts and uart1_tx are output signals; therefore, clear the INPUTENABLE bit of the corresponding pad configuration register. Because uart1_cts and uart1_rx are input signals, set the INPUTENABLE bit of the corresponding pad configuration register.

NOTE: The order for setting the previous pad configuration bits is not important.

13.5.5 I/O Power Optimization Guidelines

To optimize I/O power, it is important to avoid unconnected or incorrectly pulled pins. According to the type of pins, the way to reduce power consumption can differ. [Table 13-69](#) shows the three available pin (or ball) types.

Table 13-69. Pin Types

Input	Output	Bidirectional
 scm-026	 scm-027	 scm-028

The configuration differs according to the I/O cell types. The following describes some pieces of advice which can be useful to avoid extra current leakage:

- For input pins, use a pullup/down when possible.
 - For output pins, check existing pulls to avoid conflicts.
 - For bidirectional pins, reconfigure the pin as an output driving 0 when possible.
- Some I/O configurations involve modifications during the software setup of I/Os and sometimes require several hardware updates.

[Figure 13-26](#) shows how to optimize the power consumption of pads.

Figure 13-26. I/O Power Optimization Flow Chart

scm-029

The following notes give additional explanation about the pin configuration.

1. To avoid unconnected pins, the configuration depends on its use:
 - If the pin is not driven externally, a pullup/down is required.
 - Otherwise, a pullup/down is not necessary.
2. Pull conflicts occur when there are different pulls on the same line. In order to correctly configure the pin, avoid external and internal pull together.
3. Logic conflicts consist in different electrical levels at the same time on one line. This can occur when several devices are connected to the same line. The two possible cases are:
 - If no external device drives the line, configure the pin to drive a 0.
 - If another device drives the line, either the same value has to be driven or the pin has to be disconnected (HZ).

NOTE: It is advised to use high impedance logical state either on the device or the external component when the line is driven by both components.

The I/O pads are software-controlled by:

- Writing to the `CONTROL.CONTROL_PADCONF_X` registers in the control module for I/O and pullup/down configuration.

NOTE: If a device pad is left unconnected, but power is supplied to the I/O, or the pad is used only as an output during the lifetime of the application, it is recommended to keep its corresponding CONTROL_CORE/WKUP_PAD0_X_PAD1_Y.INPUTENABLE pad configuration bit set to 0b0. This keeps the input buffer disabled and reduces static current consumption.

- Writing to the GPIOi.GPIO_OE registers in the GPIO module for I/O configuration. For more information about how to configure the I/O pads, see [Section 13.4.4, Pad Functional Multiplexing and Configuration](#).

For more information about the GPIO module, see [Chapter 25, General-Purpose Interface](#).

NOTE: For a correct configuration of each pin direction (input, output, bidirectional), the CONTROL.[CONTROL_PADCONF_X](#) and the GPIOi.GPIO_OE registers must be written.

For unconnected device pads, safe_mode pad configuration is recommended if available. [Table 13-70](#) summarizes recommendations for the configuration of unconnected pads (in terms of mux mode, input, and output buffer states) for all cases, including those where safe_mode configuration is not available.

Table 13-70. Recommended Configuration For Unconnected Device Pads

Pad MuxMode Set Features			Power-on Reset Default Configuration		Recommended Unconnected Device Pad Configuration					
Safe Mode Available?	GPIO Function Available?	More Than One (Non-GPIO) Function Available?	Multiplexed Signal Direction at Pad	Pad State ⁽¹⁾	Multiplexed Signal Direction at Pad	Pad State	Input Buffer Disabled?	Output Buffer Disabled?	MUX Function Selected	
Yes	N/A	N/A	Input	PU	Safe Mode	PU	Yes ⁽²⁾	N/A	SAFE MODE ⁽³⁾	
Yes	N/A	N/A	Input	PD	Safe Mode	PD	Yes	N/A	SAFE MODE	
Yes	N/A	N/A	Output	1	Safe Mode	PD	Yes	N/A	SAFE MODE	
Yes	N/A	N/A	Output	0	Safe Mode	PD	Yes	N/A	SAFE MODE	
Yes	N/A	N/A	–	Hi-Z	Safe Mode	PD	Yes	N/A	SAFE MODE	
No	Yes	N/A	Input	PU	Input	PU	Yes	Yes ⁽⁴⁾	GPIO_XX ⁽⁵⁾	
No	Yes	N/A	Input	PD	Input	PD	Yes	Yes	GPIO_XX	
No	Yes	N/A	Output	1	Input	PD	Yes	Yes	GPIO_XX	
No	Yes	N/A	Output	0	Input	PD	Yes	Yes	GPIO_XX	
No	Yes	N/A	–	Hi-Z	Input	PD	Yes	Yes	GPIO_XX	
No	No	Yes	Input	PU	Input	PU	Yes	N/A ⁽⁴⁾	N/A (default)	
No	No	Yes	Input	PD	Input	PD	Yes	N/A	N/A (default)	
No	No	Yes	Output	1	Output	1	Yes	N/A	N/A (default) ⁽⁶⁾	
No	No	Yes	Output	0	Output	0	Yes	N/A	N/A (default) ⁽⁶⁾	
No	No	Yes	–	Hi-Z	Input	PD	Yes	N/A	N/A (default)	
No	No	No	Input	PU	Input	PU	Yes	N/A ⁽⁴⁾	N/A (default)	
No	No	No	Input	PD	Input	PD	Yes	N/A	N/A (default)	
No	No	No	Output	1	Output	1	Yes	N/A	N/A (default)	
No	No	No	Output	0	Output	0	Yes	N/A	N/A (default)	
No	No	No	–	Hi-Z	Input	PD	Yes	N/A	N/A (default)	

(1) PU = Pullup; PD = Pulldown; Hi-Z = High impedance

(2) If a certain device pad is left unconnected, its associated padconfiguration register INPUTENABLE bit must be explicitly disabled in software (set to 0b0), regardless of pad MUXMODE bit field value.

(3) If a certain pad has a defined safe_mode and is left unconnected in an application , it is recommended to keep its padconfiguration MuxMode value at 0x7 (that is, safe_mode).

(4) There is no software control over the pad associated output buffer in the Control Module. In case of a GPIO function selection, the output buffer is hardware enabled once the user enables corresponding pin output direction in the GPIOx.GPIO_OE control register.

(5) If a certain pad does not have a safe_mode, but has an associated GPIO function, it is recommended to set its padconfiguration register MuxMode to select the GPIO mode.

(6) If one of the other mux modes available is bidirectional or input-only, then the nondefault mux mode could be used and configured with input disabled.

13.6 SCM Register Manual

13.6.1 SCM Instance Summary

[Table 13-71](#) lists the base address and address space for the SCM instances.

Table 13-71. SCM Instance Summary

Module Name	Base Address
INTERFACE	0x4800 2000
GENERAL	0x4800 2270
GENERAL_WKUP	0x4800 2A5C

A MEM_WKUP (1KB) instance exists; it based at 0x4800 2600. This instance is used in a save-and-restore context. See [Table 13-75](#) for more details.

To configure pads, two instances exist:

- PADCONFS instance based at 0x4800 2030. For more information, see [Table 13-73](#).
- PADCONFS_WKUP instance based at 0x4800 2A00. See [Table 13-76](#).

13.6.2 SCM Register Summary

NOTE: All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little endian encoding).

[Table 13-72](#) lists the INTERFACE registers.

Table 13-72. INTERFACE Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
CONTROL_REVISION	R	32	0x0000 0000	0x4800 2000

SCM Register Manual

- SCM Register Summary: [6]

13.6.3.2 PADCONFS Register Description

Each 32-bit PADCONF register gathers the configuration of two pads. For example, CONTROL.CONTROL_PADCONF_GPMC_7 is used to configure gpmc_7 pad (bits [15:0]) and gpmc_8 pad (bits [31:16]). See [Figure 13-8](#) for more information about PADCONFS registers.

According to the pad type, some features are configurable or not. [Table 13-82](#) gives the description of a fully configurable pad.

Table 13-82. CONTROL_PADCONF_X

Address Offset	0x0000 0000 - 0x0000 05C8														
Physical base address	0x4800 2030 Instance PADCONFS														
Description	Pad configuration register														
Type	RW

Bits	Field Name	Description	Type	Reset
31	WAKEUPEVENT1 See ⁽¹⁾	Pad_x wake-up event status latched in the I/O: 0: No wake-up event occurred 1: A wake-up event occurred	R	0
30	WAKEUPENABLE1	Input pad wake-up enable (and OFF mode input enable value) for pad_x: 0: Wake-up detection on is disabled. 1: Wake-up detection on is enabled.	R/W	0
29	OFFPULLTYPESELECT1	Off mode PullUp/Down selection for pad_x: 0: PullDown selected 1: PullUp selected	R/W	0
28	OFFPULLUDENABLE1	Off mode PullUp/Down enable for pad_x: 0: PullUp/Down disabled 1: PullUp/Down enabled	R/W	0
27	OFFOUTVALUE1	Off mode pad_x output value	R/W	0
26	OFFOUTENABLE1	Off mode pad_x output enable value: (Warning: This is an active low signal.) 0: Output enabled 1: Output disabled	R/W	0
25	OFFENABLE1	Off mode pad_x state override control: 0: Off mode disabled 1: Off mode enabled	R/W	0
24	INPUTENABLE1	Input enable value for pad_x	R/W	1
23:21	RESERVED	Reserved	R	0
20	PULLTYPESELECT1	PullUp/Down selection for pad_x: 0: PullDown selected 1: PullUp selected	R/W	Pad dependent
19	PULLUDENABLE1	PullUp/Down enable for pad_x: 0: PullUp/Down disabled 1: PullUp/Down enabled	R/W	Pad dependent
18:16	MUXMODE1	Functional multiplexing selection for pad_x	R/W	Pad dependent
15	WAKEUPEVENT0 See ⁽¹⁾	Pad_y wake-up event status latched in the I/O: 0: No wake-up event occurred 1: A wake-up event occurred	R	Pad dependent
14	WAKEUPENABLE0	Input pad wake-up enable (and OFF mode input enable value) for pad_y: 0: Wake-up detection on is disabled. 1: Wake-up detection on is enabled.	R/W	0
13	OFFPULLTYPESELECT0	Off mode PullUp/Down selection for pad_y: 0: PullDown selected 1: PullUp selected	R/W	0

⁽¹⁾ The WAKEUPEVENT1 of the CAM_D0 register is swapped with the WAKEUPEVENT0 of CAM_D1.

Bits	Field Name	Description	Type	Reset
12	OFFPULLUDENABLE0	Off mode PullUp/Down enable for pad_y: 0: PullUp/Down disabled 1: PullUp/Down enabled	R/W	0
11	OFFOUTVALUE0	Off mode pad_y output value	R/W	0
10	OFFOUTENABLE0	Off mode pad_y output enable value: (Warning: This is an active low signal.) 0: Off mode enabled. 1: Off mode disabled	R/W	0
9	OFFENABLE0	Off mode pad_y state override control: 0: Off mode disabled. 1: Off mode enabled	R/W	0
8	INPUTENABLE0	Input enable value for pad_y	R/W	1
7:5	RESERVED	Reserved	R	0
4	PULLTYPESELECT0	PullUp/Down selection for pad_y: 0: PullDown selected 1: PullUp selected	R/W	Pad dependent
3	PULLUDENABLE0	PullUp/Down enable for pad_y: 0: PullUp/Down disabled 1: PullUp/Down enabled	R/W	Pad dependent
2:0	MUXMODE0	Functional multiplexing selection for pad_y	R/W	Pad dependent

Table 13-83. Register Call Summary for Register CONTROL_PADCONF_X

SCM Programming Model

- I/O Power Optimization Guidelines: [0] [1]

CAUTION

The OFFOUTENABLE and OFFOUTVALUE bits are functional only if the pad configuration supports output mode on at least one MUXMODE. For a pad that supports only the input feature, the OFFOUTENABLE and OFFOUTVALUE bits cannot be configured (they are don't care and read always returns 0).

NOTE: The bit field gives the field number for the pairs of pads gathered in each register.

Table 13-84 describes the reset values, the capabilities, and the corresponding register for each pad.

NOTE:

- In the following table, a dash (-) indicates that the field is hardwired to logic 0. No corresponding control block ports are implemented for these bits.
 - Reset values of fields MuxMode and PU/PD vary for different pads. Hence the reset values of these bit fields are shown in Table 13-84, wherever supported.
-

CAUTION

During booting process, Device Boot ROM code alters the padconfiguration bitfields, depending on the targeted booting interface or memory. The Boot Code does not restore the initial padconf reset values at the end of the booting procedure.

13.6.3.3 GENERAL Register Description

Table 13-85 through Table 13-255 describe the GENERAL registers bits.

Table 13-85. CONTROL_PADCONF_OFF

Address Offset	0x0000 0000																				
Physical address	0x4800 2270										Instance	GENERAL									
Description	Off mode pad configuration register																				
Type	RW																				
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0	WKUPCTRLCLOCKDIV	STARTSAVE	FORCEOFFMODEEN															
RESERVED																					

Bits	Field Name	Description	Type	Reset
31:3	RESERVED	Read returns reset value.	R	0x0000000
2	WKUPCTRLCLOCKDIV	Wkup_ctrl module clock divider 0: Clock is divided by 4 1: Clock is divided by 2	R/W	0x0
1	STARTSAVE	Start pad configuration registers save mechanism 0x0: Save is not started. 0x1: Save is running. This bit is auto-cleared after 8 interface clock cycles.	R/W	0x0
0	FORCEOFFMODEEN	Force OFF mode active 0x0: OFF mode is not forced active. 0x1: OFF mode is forced active.	R/W	0x0

Bits	Field Name	Description	Type	Reset
31	PRG_MCBSP2_LB	Format used in the field name below is : (programmable_group_name)_ (configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
30	PRG_CLKOUT2_LB	Format used in the field name below is : (programmable_group_name)_ (configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
29	PRG_ETK_CUT2_LB	Format used in the field name below is : (programmable_group_name)_ (configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
28	PRG_ETK_CUT1_LB	Format used in the field name below is : (programmable_group_name)_ (configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
27	PRG_CHASSIS_AD2D_LB	Format used in the field name below is : (programmable_group_name)_ (configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
26:25	PRG_CHASSIS_CLOCK_SC	Slew rate control bits. Format used in the field name below is: (programmable_group_name)_ (configurable_pin on IO cell) See Table 13-21 for the allowed SC vs LB bit field combinations	RW	0x1
24:23	PRG_CHASSIS_CLOCK_LB	Effective TL length and farend capacitive load controls. This bit allows control of programmable drive/slew control on IO cell. Format used in the field name below is: (programmable_group_name)_ (configurable_pin on IO cell) See Table 13-21 for the allowed SC vs LB bit field combinations	RW	0x0

Bits	Field Name	Description	Type	Reset
22:21	PRG_CHASSIS_INT_SC	Slew rate control bits. Format used in the field name below is: (programmable_group_name)_(_configurable_pin on IO cell) See Table 13-21 for the allowed SC vs LB bit field combinations	RW	0x1
20:19	PRG_CHASSIS_INT_LB	Effective TL length and farend capacitive load controls. This bit allows control of programmable drive/slew control on IO cell. Format used in the field name below is: (programmable_group_name)_(_configurable_pin on IO cell) See Table 13-21 for the allowed SC vs LB bit field combinations	RW	0x0
18:17	PRG_CHASSIS_DMA_SC	Slew rate control bits. Format used in the field name below is: (programmable_group_name)_(_configurable_pin on IO cell) See Table 13-21 for the allowed SC vs LB bit field combinations	RW	0x1
16:15	PRG_CHASSIS_DMA_LB	Effective TL length and farend capacitive load controls. This bit allows control of programmable drive/slew control on IO cell. Format used in the field name below is: (programmable_group_name)_(_configurable_pin on IO cell) See Table 13-21 for the allowed SC vs LB bit field combinations	RW	0x0
14	PRG_CHASSIS_PRCM_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm: 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
13:12	PRG_I2C1_HS	The bits select a proper resistor value for the I2C1 pullups for a given load range at FS / HS modes. Format used in the field name below is: (programmable_group_name)_(_configurable_pin on IO cell) FS mode : 0b00: 4,5K Ohms / 5-15pF cap.load 0b01: 2,1K Ohms /15-50pF cap.load 0b10: 860 Ohms / 50-150pF cap.load 0b11: Reserved HS mode : 0b00: 1,66K Ohms / 5-12pF cap.load 0b01: 920 Ohms / 12-25pF cap.load 0b10: 500 Ohms/ 25-50pF cap.load 0b11: 300 Ohms/ 50-80pF cap.load See Table 13-24 for example [LB1:LB0] bit field vs PRG_I2C1_PULLUPRESX bit combinations.	RW	0x0
11:10	PRG_I2C2_FS	The bits select a proper resistor value for the I2C2 pull-ups for a given load range at FS / HS modes. Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) FS mode : 0b00: 4,5K Ohms / 5-15pF cap.load 0b01: 2,1K Ohms /15-50pF cap.load 0b10: 860 Ohms / 50-150pF cap.load 0b11: Reserved HS mode : 0b00: 1,66K Ohms / 5-12pF cap.load 0b01: 920 Ohms / 12-25pF cap.load 0b10: 500 Ohms/ 25-50pF cap.load 0b11: 300 Ohms/ 50-80pF cap.load See Table 13-24 for example [LB1:LB0] bit field vs PRG_I2C2_PULLUPRESX bit combinations.	RW	0x0

Bits	Field Name	Description	Type	Reset
9:8	PRG_I2C3_FS	The bits select a proper resistor value for the I2C3 pull-ups for a given load range at FS / HS modes. Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) FS mode : 0b00: 4.5K Ohms / 5-15pF cap.load 0b01: 2.1K Ohms / 15-50pF cap.load 0b10: 860 Ohms / 50-150pF cap.load 0b11: Reserved HS mode : 0b00: 1.66K Ohms / 5-12pF cap.load 0b01: 920 Ohms / 12-25pF cap.load 0b10: 500 Ohms/ 25-50pF cap.load 0b11: 300 Ohms/ 50-80pF cap.load See Table 13-24 for example [LB1:LB0] bit field vs PRG_I2C3_PULLUPRESX bit combinations.	RW	0x0
7	PRG_I2C3_PULLUPRESX	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) I2C3 pad group control for internal pull-up resistors enable: 0x0 : Enables internal pull-ups for the I2C3 pad group 0x1: Disables internal pull-ups for the I2C3 pad group	RW	0x1
6	PRG_CHASSIS_JTAG_LB_STR	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm: 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
5:4	PRG_HDQ_LB	Effective TL length and farend capacitive load controls. This bit allows control of programmable drive/slew control on IO cell. Format used in the field name below is: (programmable_group_name)_(_configurable_pin on IO cell) See Table 13-21 for the allowed SC vs LB bitfield combinations !	RW	0x0
3:2	PRG_HDQ_SC	Slew rate control bits. Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) See Table 13-21 for the allowed SC vs LB bitfield combinations !	RW	0x0
1	PRG_MCSPI1_MIN_CFG_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm: 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
0	PRG_MCSPI1_CS1_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm: 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0

Bits	Field Name	Description	Type	Reset
31	SDRC_LOWDATA	This bit allows for drive strength control on DDR output buffer for high speed operations. Format used in the field name below is : (programmable_group_name)_ (configurable_pin on IO cell) Drive strength for output load: 0x0: Load range = [2 pF-4 pF] 0x1: Load range = [4 pF-12 pF]	RW	0
30	SDRC_HIGHDATA	This bit allows for drive strength control on DDR output buffer for high speed operations. Format used in the field name below is : (programmable_group_name)_ (configurable_pin on IO cell) Drive strength for output load: 0x0: Load range = [2 pF-4 pF] 0x1: Load range = [4 pF-12 pF]	RW	0
29	SDRC_ADDRCTR	This bit allows for drive strength control on DDR output buffer for high speed operations. Format used in the field name below is : (programmable_group_name)_ (configurable_pin on IO cell) Drive strength for output load: 0x0: Load range = [2 pF-4 pF] 0x1: Load range = [4 pF-12 pF]	RW	0
28	SDRC_NCS0	This bit allows for drive strength control on DDR output buffer for high speed operations. Format used in the field name below is : (programmable_group_name)_ (configurable_pin on IO cell) Drive strength for output load: 0x0: Load range = [2 pF-4 pF] 0x1: Load range = [4 pF-12 pF]	RW	0
27	SDRC_NCS1	This bit allows for drive strength control on DDR output buffer for high speed operations. Format used in the field name below is : (programmable_group_name)_ (configurable_pin on IO cell) Drive strength for output load: 0x0: Load range = [2 pF-4 pF] 0x1: Load range = [4 pF-12 pF]	RW	0
26	PRG_GPMC_A1_LB	Format used in the field name below is : (programmable_group_name)_ (configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0

Bits	Field Name	Description	Type	Reset
25	PRG_GPMC_A2_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
24	PRG_GPMC_A3_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
23	PRG_GPMC_A4_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
22	PRG_GPMC_A5_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
21	PRG_GPMC_A6_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
20	PRG_GPMC_A7_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
19	PRG_GPMC_A8_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
18	PRG_GPMC_A9_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
17	PRG_GPMC_A10_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
16	PRG_GPMC_A11_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
15	PRG_GPMC_MIN_CFG_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0

Bits	Field Name	Description	Type	Reset
14	PRG_GPMC_D8_D15_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
13	PRG_GPMC_NCS0_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
12	PRG_GPMC_NCS1_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
11	PRG_GPMC_NCS2_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
10	PRG_GPMC_NCS3_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
9	PRG_GPMC_NCS4_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
8	PRG_GPMC_NCS5_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
7	PRG_GPMC_NCS6_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
6	PRG_GPMC_NCS7_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
5	PRG_GPMC_CLK_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
4	PRG_GPMC_NBE0_CLE_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0

Bits	Field Name	Description	Type	Reset
3	PRG_GPMC_NBE1_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
2	PRG_GPMC_NWP_LB	Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Far end load setting. Transmission Line (TL) characteristic impedance is 50 Ohm, TL capacitance =1pF / cm : 0x0: Far end load = [1pF-10pF] / TL length=[1cm-6cm] 0x1: Far end load = [10pF-16pF] / TL length=[1cm-6cm]	RW	0
1	PRG_SDMMC_PUSTRENGTH	This bit allows control of programmable pullup strength on SDMMC IO cells. Format used in the field name below is : (programmable_group_name)_(_configurable_pin on IO cell) Conducting pullup with : 0x0: 50–110 kΩ strength selected 0x1: 10–50 kΩ strength selected	RW	0
0	RESERVED	Reserved field	R	0

Table 13-256. Register Call Summary for Register CONTROL_CAMERA_PHY_CTRL

SCM Register Manual

- [SCM Register Summary: \[0\]](#)

NOTE:

- If the parallel camera sensor is the only sensor connected to one CSIPHY, the SCM.CONTROL_CAMERA0_PHY_CAMMOD and SCM.CONTROL_CAMERA1_PHY_CAMMOD bits must be set to 0x11 (that is, GPI mode).
- If the parallel camera sensor and other camera sensor (CCP2 or CSI2) are connected to the same CSIPHY, the CONTROL_CAMERAx_PHY_CAMMOD bit must be set for CCP2 or CSI2 mode, respectively, (even if only one pair is used as GPI for CPI mode). In that case, the corresponding CSI2_COMPLEXIO_CFG1.DATAx_POSITION must be set to 0x0 for the lane used in GPI mode.

Table 13-258. Register Call Summary for Register CONTROL_IDCODE

- [SCM Register Summary: \[0\]](#)

13.6.3.4 MEM_WKUP Register Description

Physical addresses 0x4800 2600 to 0x4800 29FC are memories mapped for save and restore location (1KB).

- 0x4800 2600 - 0x4800 28DC: nonaccessible (pad configuration)
- 0x4800 28E0 - 0x4800 29FC: user accessible

13.6.3.5 PADCONFS_WKUP Register Description

Each 32-bit PADCONF_WKUP register gathers the configuration of two pads. For example, CONTROL.CONTROL_PADCONF_I2C4_SCL pad is used to configure i2c4_scl pad (bits [15:0]) and i2c4_sda pad (bits [31:16]). See [Figure 13-8](#) for more information about PADCONF registers.

According to the pad type, some features are configurable or not. [Table 13-82](#) gives the description of a fully configurable pad.

[Table 13-259](#) describes the reset values, the capabilities, and the corresponding register for each pad.

NOTE:

- In the following table, a dash (-) indicates that the field is hardwired to logic 0. No corresponding control block ports are implemented for these bits.
- Reset values of fields MuxMode and PU/PD vary for different pads. Hence the reset values of these bitfields are shown in [Table 13-84](#), wherever supported.

CAUTION

During booting process, Device Boot ROM code alters the padconfiguration bitfields, depending on the targeted booting interface or memory. The Boot Code does not restore the initial padconf reset values at the end of the booting procedure.

Interprocessor Communication

This chapter describes the interprocessor communication (IPC) module in the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
14.1 IPC Overview	2660
14.2 IPC Integration	2660
14.3 IPC Mailbox Functional Description	2664
14.4 IPC Mailbox Basic Programming Model	2667
14.5 IPC Mailbox Register Manual	2672

14.1 IPC Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

[Figure 14-1](#) shows a block diagram of the interprocessor communication (IPC) module.

Figure 14-1. Simplified Block Diagram of the IPC

ipc-001

The mailbox module includes these features:

- Two mailbox message queues for microprocessor unit (MPU) and imaging video and audio accelerator (IVA2.2) communications.
- Flexible assignment of receiver and sender for each mailbox through interrupt configuration
- 32-bit message width
- Four-message FIFO depth for each message queue
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support
- Automatic idle mode for power savings

14.2 IPC Integration

[Figure 14-2](#) highlights the IPC integration in the device.

Figure 14-2. IPC Integration

ipc-002

14.2.1 Clocking, Reset, and Power-Management Scheme

14.2.1.1 Clocks

14.2.1.1.1 Module Clocks

The mailbox module receives one input clock, CORE_L4_ICLK, from the power, reset, and clock management (PRCM) module. CORE_L4_ICLK is gated internally and can be turned off to lower operating power when a module is not active. The exact frequency of this clock depends on PRCM programming.

14.2.1.2 Resets

The IPC supports both a hardware reset and a software reset.

14.2.1.2.1 Hardware Reset

The mailbox module receives its reset signal, CORE_RST (the reset signal of the CORE power domain), from the PRCM module.

14.2.1.2.2 Software Reset

The mailbox module supports a software reset by accessing the MAILBOX.[MAILBOX_SYSCONFIG\[1\]](#) SOFTRESET bit (0: normal mode, 1: module is reset).

14.2.1.3 Power Domains

The mailbox module connects to the CORE power domain.

14.2.1.4 Power Management

14.2.1.4.1 System Power Management

This section describes system power management for the mailbox module.

As part of the system-wide power-management scheme, the mailbox module supports a communication protocol with the PRCM that allows the PRCM to request the mailbox to enter a low-power state. When the mailbox module acknowledges a low-power-mode request from the PRCM, the clock to the module is gated off at the PRCM clock generator. Because the clock is disabled at the source, the low-power mode offers lower power consumption than the internal clock-gating method in the local power management.

The PRCM.CM_ICLKEN1_CORE[7] EN_MAILBOXES bit in the PRCM module controls the mailbox clock. When this bit is 1, the clock to the mailbox module is enabled; otherwise, the clock is disabled (see [Chapter 3, Power, Reset, and Clock Management](#), for more information).

The mailbox module can be configured using the MAILBOX.[MAILBOX_SYSConfig\[4:3\]](#) SIDLEMODE field to one of the following acknowledgment modes:

- No-idle mode: The mailbox module never enters the idle state.
- Force-idle mode: The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- Smart-idle mode: After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

[Table 14-1](#) describes the mailbox power-management modes.

Table 14-1. Mailbox Power Management Modes

Power-Management Mode Requested by the PRCM	MAILBOX. MAILBOX_SYSConfig[4:3] SIDLEMODE Bit Field (Offset: 0x010)
Force-idle	00
No-idle	01
Smart-idle	10
Reserved (not used)	11

NOTE: The mailbox idle status can be read from the PRCM.CM_IDLEST1_CORE[7] ST_MAILBOXES bit. When this bit is 0, the mailbox module cannot be accessed; otherwise, the mailbox module can be accessed (see [Chapter 3, Power, Reset, and Clock Management](#), for more information).

14.2.1.4.2 Module Power Management

This section describes local power management for the mailbox module.

To conserve power, the mailbox module supports an automatic idle mode whenever no activity is detected on the mailbox L4-Core interconnect interface. The automatic idle mode is enabled or disabled through the MAILBOX.[MAILBOX_SYSConfig\[0\]](#) AUTOIDLE bit.

When the MAILBOX.[MAILBOX_SYSConfig\[0\]](#) AUTOIDLE bit is asserted, the automatic idle mode is enabled in cases in which no activity is detected on the L4-Core interconnect interface, and the mailbox clock is disabled internally to the module, thus reducing power consumption.

When new activity is detected on the L4-Core interconnect interface, the clock is restarted with no latency penalty. After reset, the automatic idle mode is disabled; therefore, it is recommended that software enable the automatic idle mode for reduced power consumption.

NOTE: The PRCM.CM_AUTOIDLE1_CORE[7] AUTO_MAILBOXES bit controls whether the mailbox interface clock is enabled or disabled in synchronization with the CORE power domain state transition (see [Chapter 3, Power, Reset, and Clock Management](#), for more information).

14.2.2 Hardware Requests

14.2.2.1 Interrupt Requests

The mailbox module can generate two interrupts:

- MAIL_U0_MPUIRQ, mapped on M_IRQ_26 of the MPU subsystem interrupt controller
- MAIL_U1_IVA2_IRQ, mapped on IVA2_IRQ[10] of the IVA2.2 subsystem interrupt controller

Each interrupt allows the user (MPU subsystem or IVA2.2 subsystem) of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

14.2.2.2 Idle Handshake Protocol

The PRCM module handles an idle handshake protocol for the mailbox module. The PRCM requires the mailbox module to enter idle mode. The mailbox module acknowledges when it is ready.

14.3 IPC Mailbox Functional Description

NOTE: In the mailbox functional description, u is the user number from 0 to 1 and m is the mailbox number from 0 to 1.

The mailbox module provides a means of communication through message queues among the MPU and the IVA2.2. The two individual mailbox modules, or FIFOs, can associate with any of the processors using the MAILBOX.[MAILBOX_IRQENABLE_u](#) registers.

The mailbox module includes the following two user subsystems:

- User 0: MPU subsystem ($u = 0$)
- User 1: IVA2.2 subsystem ($u = 1$)

Each user has a dedicated interrupt signal from the mailbox module and a dedicated pair of interrupt enabling and status registers. Each MAILBOX.[MAILBOX_IRQSTATUS_u](#) interrupt status register corresponds to a particular user. A user can query its interrupt status register through the L4-Core interconnect.

14.3.1 Block Diagram

Figure 14-3 shows the mailbox block diagram.

Figure 14-3. Mailbox Block Diagram

ipc-003

14.3.2 Mailbox Assignment

14.3.2.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX.[MAILBOX IRQENABLE_u](#) register. The receiver reads the MAILBOX.[MAILBOX MESSAGE_m](#) register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX.[MAILBOX FIFOSTATUS_m](#) and/or MAILBOX.[MAILBOX MSGSTATUS_m](#) registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX.[MAILBOX IRQENABLE_u](#) register, where u is the number of the receiving user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX.[MAILBOX FIFOSTATUS_m](#) or MAILBOX.[MAILBOX MSGSTATUS_m](#) registers
- Write the message to the corresponding MAILBOX.[MAILBOX MESSAGE_m](#) register, if space is available.

The sender should use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX.[MAILBOX IRQENABLE_u](#) register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX.[MAILBOX IRQSTATUS_u](#) register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the same register location acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

14.3.3 Sending and Receiving Messages

14.3.3.1 Description

When a 32-bit message is written to the MAILBOX.[MAILBOX MESSAGE_m](#) register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the MAILBOX.[MAILBOX FIFOSTATUS_m](#) register to check that the mailbox message queue is not full before writing a new message to it.

Reading the MAILBOX.[MAILBOX MESSAGE_m](#) register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX.[MAILBOX MESSAGE_m](#) register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX.[MAILBOX MSGSTATUS_m](#) register.

14.3.4 16-Bit Register Access

14.3.4.1 Description

So that 16-bit processors can access the mailbox module, the device allows 16-bit register read and write access, with restrictions for the MAILBOX.[MAILBOX_MESSAGE_m](#) registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02).

All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the MAILBOX.[MAILBOX_MESSAGE_m](#) registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

CAUTION

When using 16-bit accesses, it is critical to ensure that the mailbox used has only one assigned receiver and only one assigned sender.

When using 16-bit accesses to the MAILBOX.[MAILBOX_MESSAGE_m](#) registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is due to the update operation by the message FIFO of the MAILBOX.[MAILBOX_MSGSTATUS_m](#) registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a MAILBOX.[MAILBOX_MESSAGE_m](#) are accessed.

14.4 IPC Mailbox Basic Programming Model

14.4.1 Initialization Flow for the Mailbox Module

The initialization flow for the mailbox module consists of the following steps:

1. Perform a software reset of the mailbox module (see [Section 14.4.1.1, Software Reset](#)).
2. Set the idle mode and clock configuration of the mailbox module (see [Section 14.4.1.2, Idle Mode and Clock Configuration](#)).

14.4.1.1 Software Reset

To perform a software reset, write 1 in the MAILBOX.[MAILBOX_SYSCONFIG\[1\]](#) SOFTRESET bit. The MAILBOX.[MAILBOX_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is 1.

When the software reset completes, the MAILBOX.[MAILBOX_SYSCONFIG\[1\]](#) SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing mailbox operations.

CAUTION

When performing a software reset by writing 1 in the MAILBOX.[MAILBOX_SYSCONFIG\[1\]](#) SOFTRESET bit, 0 must be written in the other bits of the MAILBOX.[MAILBOX_SYSCONFIG](#) register.

14.4.1.2 Idle Mode and Clock Configuration

The idle mode and clock configuration is done by setting the MAILBOX.[MAILBOX_SYSCONFIG\[4:3\]](#) SIDLEMODE field and the MAILBOX.[MAILBOX_SYSCONFIG\[0\]](#) AUTOIDLE bit (see [Section 14.5, Mailbox Register Manual](#), for more information).

14.4.2 Mailbox Assignment

Before communicating, mailboxes can be explicitly assigned to a user using the appropriate MAILBOX.[MAILBOX_IRQENABLE_u](#) register. The software must ensure that only one sender and one receiver are assigned per mailbox.

For example, to assign mailbox 1 ($m = 1$) to the MPU ($u = 0$, see [Section 14.3, Mailbox Functional Description](#), for the user number) as a receiver, set the MAILBOX.[MAILBOX_IRQENABLE_0\[2\]](#) NEWMSGENABLEUUMB1 bit to generate an interrupt to the MPU when a new message is received in mailbox 1.

To assign mailbox 0 ($m = 0$) to the MPU ($u = 0$) as a sender, set the MAILBOX.[MAILBOX_IRQENABLE_0\[1\]](#) NOTFULLENABLEUUMB0 bit to generate an interrupt to the MPU when the message queue of mailbox 0 is not full.

14.4.3 Mailbox Communication Preparation

Before communicating with another user, the sender must first use one of the following methods to determine that the mailbox message FIFO queue is not full:

- Poll the MAILBOX.[MAILBOX_FIFOSTATUS_m\[0\]](#) FIFOFULLMB bit or the MAILBOX.[MAILBOX_MSGSTATUS_m\[2:0\]](#) NBOFMSGMB field to determine if there is an open slot available to write a message.
- If the queue-not-full interrupt is enabled by setting the corresponding bit in the MAILBOX.[MAILBOX_IRQENABLE_u](#) register, an interrupt to the sender indicates that the mailbox has an available slot. To avoid continuous interrupt to the sender, it is recommended that the software waits until the message queue is full by reading the MAILBOX.[MAILBOX_MSGSTATUS_m\[2:0\]](#) NBOFMSGMB field before enabling the interrupt in the MAILBOX.[MAILBOX_IRQENABLE_u](#) register. When a queue-not-full interrupt is generated to the sender, the interrupt should be disabled until the

message queue is full for the same reason.

The receiver can also detect new messages from another user using two methods:

- Poll the MAILBOX.MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB bit or the MAILBOX.MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB field.
- Use a new message ISR (interrupt service routine). In this case, the receiver must enable the appropriate interrupt in the MAILBOX.MAILBOX_IRQENABLE_u register.

NOTE: After an interrupt is generated, and before exiting the ISR, write 1 in each bit responsible for this generation in the MAILBOX.MAILBOX_IRQSTATUS_u register, thereby clearing these bits.

14.4.4 Mailbox Communication Sequence

When a message slot is available in the mailbox, a message can be transmitted by a sender to a receiver using the following steps:

1. The sender writes a message in the MAILBOX.MAILBOX_MESSAGE_m register. This results in the following actions:
 - The message is stored at the tail of the FIFO queue of mailbox m , and the MAILBOX.MAILBOX_FIFOSTATUS_m and MAILBOX.MAILBOX_MSGSTATUS_m registers are updated.
 - If the FIFO queue was previously empty, a new message interrupt can be generated to the receiver to which the mailbox is allocated; otherwise, the interrupt is already asserted and remains so.
2. The receiver can either use an ISR or poll the MAILBOX.MAILBOX_FIFOSTATUS_m or MAILBOX.MAILBOX_MSGSTATUS_m registers to detect new messages and read them by accessing the MAILBOX.MAILBOX_MESSAGE_m register.
 - If using interrupts, the receiver enters the ISR when it detects the new message interrupt. The receiver checks both the MAILBOX.MAILBOX_IRQSTATUS_u register to determine the source of the interrupt and the MAILBOX.MAILBOX_MSGSTATUS_m register(s) to determine the number of messages in the FIFO queue.
 - The receiver can poll the appropriate MAILBOX.MAILBOX_MSGSTATUS_m register(s) to check the status and determine if there are any pending messages to read. The receiver can read the MAILBOX.MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB field to determine how many messages are available.
3. Using either ISR or polling method, when the receiver determines that it has a message pending in a mailbox, it repeatedly reads the MAILBOX.MAILBOX_MESSAGE_m register to remove all messages from the FIFO queue until a read in the MAILBOX.MAILBOX_MSGSTATUS_m register indicates no more messages are available (MAILBOX.MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB field = 0x00).
4. After reading all of the messages, the receiver can acknowledge the new message interrupt by writing 1 in the appropriate bit of the MAILBOX.MAILBOX_IRQSTATUS_u register to clear the interrupt flag before exiting the ISR.

14.4.5 Example of Communication

This example shows how communication is established between the MPU and IVA2.2 subsystems in the device. The MPU subsystem sends messages to the IVA2.2 subsystem through mailbox 0, and the IVA2.2 subsystem sends messages to the MPU subsystem through mailbox 1.

To establish communication, the software follows these steps:

1. Turn on the automatic idle feature by writing 1 in the MAILBOX.MAILBOX_SYSCONFIG[0] AUTOIDLE bit.

2. Configure the mailbox in smart-idle mode by setting the MAILBOX.[MAILBOX_SYSConfig\[4:3\]](#) SIDLEMODE field in smart-idle mode (smart-idle is the recommended mode; see [Section 14.5, Mailbox Register Manual](#), for more information). Smart-idle mode allows the PRCM low-power-mode requests to be acknowledged only after clearing any pending interrupts.
3. Write 1 in the MAILBOX.MAILBOX_IRQENABLE_1[0] NEWMSGENABLEUUMB0 bit to enable interrupts to the IVA2.2 subsystem when a new message is received in mailbox 0.
4. Write 1 in the MAILBOX.MAILBOX_IRQENABLE_0[2] NEWMSGENABLEUUMB1 bit to enable interrupts to the MPU subsystem when a new message is received in mailbox 1.
5. Enable interrupts in the corresponding subsystems.

14.4.5.1 Sending a Message (Polling Method)

To send a message using the polling method, the MPU or IVA2.2 subsystem follows these steps:

1. The MPU subsystem (or IVA2.2 subsystem) determines if the message queue of mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) is full by reading the MAILBOX.MAILBOX_FIFOSTATUS_0[0] FIFOFULLMB bit (or the MAILBOX.MAILBOX_FIFOSTATUS_1[0] FIFOFULLMB bit for the IVA2.2 subsystem).
2. If the MAILBOX.MAILBOX_FIFOSTATUS_0[0] FIFOFULLMB bit (or the MAILBOX.MAILBOX_FIFOSTATUS_1[0] FIFOFULLMB bit for the IVA2.2 subsystem) is 0, mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) has a message slot available to store a new message; go to step 4.
3. If the MAILBOX.MAILBOX_FIFOSTATUS_0[0] FIFOFULLMB bit (or the MAILBOX.MAILBOX_FIFOSTATUS_1[0] FIFOFULLMB bit for the IVA2.2 subsystem) is 1, mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) is full; go back to step 1.
4. The MPU subsystem (or IVA2.2 subsystem) can send a message by writing it into the MAILBOX.MAILBOX_MESSAGE_0 register (or the MAILBOX.MAILBOX_MESSAGE_1 register for the IVA2.2 subsystem).

14.4.5.2 Sending a Message (Interrupt Method)

To send a message using the interrupt method, the MPU or IVA2.2 subsystem follows these steps:

1. To avoid continuous interruption, the MPU subsystem (or the IVA2.2 subsystem) must determine if mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) is full by reading the MAILBOX.MAILBOX_FIFOSTATUS_0[0] FIFOFULLMB bit (or the MAILBOX.MAILBOX_FIFOSTATUS_1[0] FIFOFULLMB bit for the IVA2.2 subsystem).
2. If mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) is full, the MPU subsystem (or the IVA2.2 subsystem) can enable the queue-not-full interrupt by setting the MAILBOX.MAILBOX_IRQENABLE_0[1] NOTFULLENABLEUUMB0 bit (or the MAILBOX.MAILBOX_IRQENABLE_1[3] NOTFULLENABLEUUMB1 bit for the IVA2.2 subsystem), and perform another task before an interrupt occurs; go to step 4).
3. If mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) is not full, the MPU can go back to step 1 and wait for mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) to fill, or the MPU can send a message, if necessary, by writing in the MAILBOX.MAILBOX_MESSAGE_0 register (or the MAILBOX.MAILBOX_MESSAGE_1 register for the IVA2.2 subsystem).
4. After receiving an interrupt, the MPU subsystem (or the IVA2.2 subsystem) enters the ISR and reads the MAILBOX.MAILBOX_IRQSTATUS_0[1] NOTFULLSTATUSUUMB0 bit (or the MAILBOX.MAILBOX_IRQSTATUS_1[3] NOTFULLSTATUSUUMB1 bit for the IVA2.2 subsystem) to determine if mailbox 0 (or mailbox 1 for the IVA2.2 subsystem) is not full and thus send its message. The MPU subsystem writes the message in the MAILBOX.MAILBOX_MESSAGE_0 register (or the MAILBOX.MAILBOX_MESSAGE_1 register for the IVA2.2 subsystem). The MPU subsystem (or the IVA2.2 subsystem) then acknowledges the interrupt by writing 1 in the MAILBOX.MAILBOX_IRQSTATUS_0[1] NOTFULLSTATUSUUMB0 bit (or the MAILBOX.MAILBOX_IRQSTATUS_1[3] NOTFULLSTATUSUUMB1 bit for the IVA2.2 subsystem).

NOTE: To send several messages, a subsystem or processor must determine if the message queue of mailbox m has enough available slots by checking the MAILBOX.MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB bit field before writing all of the messages in this mailbox (see [Section 14.5, Mailbox Register Manual](#), for more information).

14.4.5.3 Receiving Messages (Interrupt Method)

After receiving an interrupt indicating that a new message is received, the MPU or IVA2.2 subsystem follows these steps:

1. The MPU subsystem (or the IVA2.2 subsystem) determines how many messages are stored in the message queue of mailbox 1 by reading the MAILBOX.MAILBOX_MSGSTATUS_1[2:0] NBOFMSGMB field (or the MAILBOX.MAILBOX_MSGSTATUS_0[2:0] NBOFMSGMB bit field for the IVA2.2 subsystem).
2. The MPU subsystem (or the IVA2.2 subsystem) reads the MAILBOX.MAILBOX_MESSAGE_1 register (or the MAILBOX.MAILBOX_MESSAGE_0 register for the IVA2.2 subsystem) as many times as there are messages in mailbox 1 (or mailbox 0 for the IVA2.2 subsystem).
3. Finally, the MPU subsystem (or the IVA2.2 subsystem) acknowledges the interrupt by writing 1 in the MAILBOX.MAILBOX_IRQSTATUS_0[2] NEWMSGSTATUSUUMB1 bit (or the MAILBOX.MAILBOX_IRQSTATUS_1[0] NEWMSGSTATUSUUMB0 bit for the IVA2.2 subsystem).

NOTE: After the interrupt is acknowledged, if the mailbox message queue is not empty, the interrupt is reasserted.

Memory Management Units

This chapter describes the memory management units (MMUs).

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
15.1 MMU Overview	2680
15.2 MMU Integration	2681
15.3 MMU Functional Description	2684
15.4 MMU Basic Programming Model	2696
15.5 MMU Register Manual	2703

15.1 MMU Overview

The device contains three memory management units (MMUs):

- Microprocessor unit (MPU) MMU
- Camera MMU
- Image Video and Audio accelerator (IVA2.2) MMU

The camera MMU and IVA2.2 MMU share the same architecture and are both described in this chapter. The MPU MMU, which implements a different architecture, is covered in [Chapter 4, MPU Subsystem](#).

NOTE: The MMUn prefix provides information about the register instantiation, where n = 1 for the camera MMU, and n = 2 for the IVA2.2 MMU.

The MMU instances include the following main features:

- N entries fully associative translation look-aside buffer (TLB) with N = 8 for the camera MMU and N = 32 for the IVA2.2 MMU
- 1 interrupt line out to the MPU subsystem
- 32-bit virtual addresses, 32-bit physical address
- Mapping size: 4KB and 64KB pages, 1MB section, and 16MB supersection
- Predefined (static) or table-driven (hardware table walker) software translation strategies

[Figure 15-1](#) shows the MMU instances in the device.

Figure 15-1. Device MMU Instances

15.2 MMU Integration

The MMU communicates accesses from the requestor (either the camera subsystem or the IVA2.2) to the L3 main interconnect, performing virtual to physical address translation. The camera MMU is programmed through the L4-core interconnect. The IVA2.2 MMU is programmed through the L3 interconnect. Both MMU error conditions are signaled as interrupts to the system master processor (that is, the MPU).

[Figure 15-2](#) and [Figure 15-3](#) show the system integration of the camera MMU instance and the IVA2.2 MMU instance.

Figure 15-2. Camera MMU System Integration

Figure 15-3. IVA2.2 MMU System Integration

15.2.1 Clock Domains

The camera MMU instance has two clock domains: the functional clock domain for the MMU, which is synchronous to the L3 interconnect clock, and the L4 interconnect clock, which is used to configure the MMU instance. Both camera MMU clocks are derived from a common reference clock generated by the power reset and clock management (PRCM) module.

The IVA2.2 MMU instance has only one clock domain: the functional clock domain for the MMU. The IVA MMU clock is generated by the DPLL2 embedded in IVA2.2, but controlled by PRCM registers.

15.2.2 Power Management

The device functional units are grouped into power domains. Each power domain is a section of the device with independent and dedicated power rails. Fifteen different power domains exist. For information about the device power management, see [Chapter 3, Power, Reset, and Clock Management](#).

The MMU instances belong to different power domains. [Table 15-1](#) shows the correspondence between the MMU instance and power domains.

Table 15-1. Power Domains of the MMU Instances

MMU Instance	Power Domain
MMU1 (camera MMU)	CAM
MMU2 (IVA2.2 MMU)	IVA2

15.2.2.1 System Power Management

As part of the device system-wide power management scheme, each MMU instance supports a communication protocol with the PRCM module that allows the PRCM module to request an MMU instance to enter a low-power state. When the MMU instance acknowledges a low-power mode request from the PRCM module, the clock to the instance is gated off at the PRCM clock generator. Because the clock is disabled at the source, the low-power mode offers lower power consumption than the internal clock gating method in the local power management.

The MMU instance can be configured through the MMUn.[MMU_SYSCONFIG\[4:3\]](#) IDLEMODE field as one of the following acknowledgement modes:

- No-idle mode: The MMU instance never enters the idle state.
- Force-idle mode: The MMU instance immediately enters the idle state after receiving a low-power mode request from the PRCM module. In this mode, the software must ensure that there are no pending interrupts before requesting this mode to go into the idle state; otherwise, an error can occur.
- Smart-idle mode: After receiving a low-power mode request from the PRCM module, the MMU instance enters the idle state only after all interrupts are acknowledged.

[Table 15-2](#) describes the MMU power management modes. For details, see the [MMU_SYSCONFIG](#) register.

Table 15-2. Power Domains of the MMU Instances

Power Management Mode Requested by the PRCM	MMUn. MMU_SYSCONFIG[4:3] IDLEMODE field
Force-idle	00
No-idle	01
Smart-idle	10
Reserved	11

15.2.2.2 Module Power Saving

To conserve power, the MMU instance supports an automatic idle mode whenever activity is not detected on the configuration register port of the MMU instance. The automatic idle mode is enabled or disabled through the MMUn.[MMU_SYSCONFIG\[0\]](#) AUTOIDLE bit.

If the MMUn.[MMU_SYSCONFIG\[0\]](#) AUTOIDLE bit is asserted, the automatic idle mode is enabled when activity is not detected on the configuration register port, and the MMU instance clock is disabled internally to the module, thereby reducing power consumption.

When new activity is detected on the configuration register port, the clock is restarted with no latency penalty. After reset, the automatic idle mode is disabled; therefore, it is recommended to enable the automatic idle mode to reduce power consumption.

15.2.3 Reset

The MMU instances are reset together with their respective reset domains. [Table 15-3](#) shows the correspondence between the MMU instances and the reset domains.

Table 15-3. Reset Domains of the MMU Instances

MMU Instance	Reset Domain
MMU1 (camera MMU)	CAM_RST
MMU2 (IVA2.2 MMU)	IVA_RST2

Software reset is applied when the MMU_n.[MMU_SYSConfig\[1\]](#) SOFTRESET is set to 1. The MMU_n.[MMU_SYSSTATUS\[0\]](#) RESETDONE bit can be polled to know the reset status.

When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

NOTE: IVA2.2 MMU can be accessed from the L3 interconnect (configuration registers) even if the DSP is still under reset (IVA_RST1 active).

15.2.4 Interrupts

Each MMU instance can generate an interrupt to the MPU on the occurrence of the following predefined set of events:

- Multi-hit fault
There is more than one TLB entry for the given virtual address.
- Table walk fault
A table walk data read generated an error.
- Emulation miss
A TLB miss was caused by an emulation access.
- Translation fault
No translation is found for the given virtual address. The hardware table walker is enabled but no valid page table entry exists for the requested address.
- TLB miss with table walk disabled
No translation is found in the TLB for the given virtual address and the table walking logic is disabled.

Each of these events can be individually enabled and disabled using the MMU_n.[MMU_IRQENABLE](#) register. If an event occurs and is enabled, an interrupt is generated to the MPU. The MPU can use the MMU_n.[MMU_IRQSTATUS](#) register to find the precise cause of the interrupt.

The MMU_n.[MMU_FAULT_AD](#) register holds the virtual address of the translation that causes the interrupt. The MMU_n.[MMU_EMU_FAULT_AD](#) indicates the address of the last emulation event causing an MMU interrupt.

[Table 15-4](#) shows the generated interrupt versus the MMU instance.

Table 15-4. Interrupts of the MMU Instances

MMU Instance	MMU Interrupt Name	MMU Interrupt Mapping
MMU1 (camera MMU)	CAM IRQ0	M_IRQ_24
MMU2 (IVA2.2 MMU)	IVA2_MMU_IRQ	M_IRQ_28

NOTE: The IVA2_MMU_IRQ (MMU2 instance) interrupt is a dedicated interrupt to the MPU subsystem.

[Chapter 6, Camera Subsystem](#), and [Chapter 5, IVA2.2 Subsystem](#), outline details about interrupt generation in the camera and IVA2.2 subsystems. For details about the MPU interrupt scheme, see [Chapter 12, Interrupt Controller](#).

15.3 MMU Functional Description

The MMUs handle the translation from virtual into physical addresses. The requestor (either the camera subsystem or the DSP mega cell or the EDMA module for IVA2.2) issues virtual addresses to the respective MMU (MMU1 for the camera subsystem and MMU2 for the IVA2.2). The MMU translates these virtual addresses into physical addresses to access the actual resource (memory) when the MMU instance is enable. That is when MMU_n.MMU_CNTL[1] MMUENABLE is set to 1.

Figure 15-4 shows the relationship between the physical address, the virtual address, and the MMU.

Figure 15-4. MMU Address Translation

15.3.1 MMU Benefits

The MMU offers two major benefits:

- Memory defragmentation: Fragmented physical memory can be translated into contiguous virtual memory without moving data.
- Memory protection: Illegal, that is, non-allowed accesses to memory locations can be detected and prevented.

Figure 15-5 shows two typical MMU use cases.

Figure 15-5. MMU Usage Examples

Figure 15-5 shows two benefits of using an MMU. Memory region 1 and memory region 2 are fragmented in physical memory. Using the MMU, they appear as one contiguous memory region in the virtual memory space.

On the other hand, task 1 and task 2 are located adjacent to each other in physical memory. In systems without an MMU, there is a danger that task 1 can accidentally write into the memory area allocated to task 2 and vice versa. Allocating task 1 and task 2 into two separate virtual memory regions prevents this problem, because a region of unmapped memory separates the two tasks. Any erroneous access to this region results in an error that can be detected easily.

15.3.2 MMU Architecture

The MMU translation process is based on translation entries stored in translation tables. One first-level translation table can exist with several optional second-level translation tables.

Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see [Section 15.3.3, Translation Tables](#).

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The TLB stores recently used translation entries, acting like a cache of the translation table.

This basic architecture is outlined in [Figure 15-6](#).

Figure 15-6. MMU Architecture

15.3.2.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is already contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. [Figure 15-7](#) summarizes the process.

Figure 15-7. Translation Process

MMU-007

15.3.3 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates
- Endianness, data access size, and the mixed property of this memory region

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

15.3.3.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4KB and 64KB pages, a 1MB section, and a 16MB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4KB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4KB memory pages with one translation table would require one million entries to span the entire 4GB address range. The table itself would be 32MB, a size that is not feasible.

However, using bigger pages greatly reduces the functionality of the OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1MB memory regions.

Each of the entries in this first-level translation table can specify the following:

- The translation properties for a big memory section. This memory section can be either 1MB (section) or 16MB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.

- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1MB page of memory. These pages can be either 64KB (large page) or 4KB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used. [Figure 15-8](#) shows this hierarchy.

Figure 15-8. Translation Hierarchy

The structure of the first and second-level translation tables and their entries are described in more detail in [Section 15.3.3.2, First-Level Translation Table](#), and [Section 15.3.3.3, Two-Level Translation](#).

15.3.3.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1MB sections. To describe a 4GB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. This mechanism is shown in [Figure 15-9](#).

Figure 15-9. First-Level Descriptor Address Calculation

To summarize, the translation table base and the translation table index together define the first-level descriptor address. [Figure 15-10](#) outlines the precise mechanism used to calculate this address.

Figure 15-10. Detailed First-Level Descriptor Address Calculation

MMU-01C

As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is $0x8000:0000 + (0x123 \ll 2) = 0x8000:048C$.

15.3.3.2.1 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1MB or 16MB sections or provides a pointer to a second-level translation table for 4KB or 64KB pages. The first-level descriptor format is shown in [Table 15-5](#).

Table 15-5. First-Level Descriptor Format

First-Level Descriptor Format												
31:24	23:20	19	18	17	16	15	14:12	11:10	9:2	1	0	
X										0	0	Fault
Second-Level Translation Table Base Address										X	0	1
Section Base Address			X	0	M	X	E (1)	X	ES	X	1	0
Supersection Base Address		X	1	M	X	E	X	ES	X	1	0	Supersection
X										1	1	Fault

⁽¹⁾ See Table 15-34 for endianness limitations.

M = Mixed region; 0 = Page-based endianness, 1 = Access-based endianness

E = Endianness: 0 = Little endian, 1 = Big endian (endianness is locked on little endian)

ES = Element Size: 00 = 8-bit, 01 = 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

15.3.3.2.2 First-Level Page Descriptor Format

If a translation granularity smaller than 1MB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

15.3.3.2.3 First-Level Section Descriptor Format

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1MB section or a 16MB supersection.

NOTE: Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1MB of memory. If an access points to a descriptor which is not initialized, MMU will behave in an unpredictable way.

In addition to the address translation itself, three parameters are specified in the section descriptors:

- Endianness

The *endianness* parameter specifies whether the memory section uses a big- or little-endian data format. This parameter is locked to little endian. See [Table 15-34](#) for more information.

- Element size

The *element size* parameter can optionally specify the data access size (8, 16, or 32 bits) for all data items in the defined section.

- Mixed region

The *mixed region* parameter specifies whether the information about the data access size is detected from the access itself (access-based detection) or if the specified element size parameter is used (page-based detection). For example, the specified element size parameter can be used when several smaller sized accesses are packed into a bigger sized access, such as two 16-bit accesses packed into one 32-bit access. In this case, with no specified data access size, 32 bits would be the access size detected, leading to an incorrect result. To avoid this problem, specify the data access size for the memory section.

15.3.3.2.4 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table. [Figure 15-11](#) summarizes the address translation process for a section.

Figure 15-11. Section Translation Summary

MMU-011

15.3.3.2.5 Supersection Translation Summary

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

[Figure 15-12](#) shows the translation mechanism for a supersection.

Figure 15-12. Supersection Translation Summary

MMU-012

15.3.3.3 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is when memory sections smaller than 1MB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address. [Figure 15-13](#) shows this indexing mechanism.

Figure 15-13. Two-Level Translation

MMU-013

Each second-level translation table describes the translation of 1MB of address space in pages of 64KB (large page) or 4KB (small page). It consists of 256 second-level descriptors describing 4KB each.

NOTE: In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor which is not initialized, MMU will behave in an unpredictable way.

15.3.3.3.1 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. [Table 15-6](#) shows the format of second-level descriptors. The translation parameters (endianness, element size, and mixed region) have the same meaning as those for sections.

Table 15-6. Second-Level Descriptor Format

Second-Level Descriptor Format										
31:16	15:12	11	10	9	8:6	5:4	3:2	1	0	
X								0	0	Fault
Large Page Base Address	X	M	X	E (¹)	X	ES	X	0	1	Large Page
Small Page Base Address	M	X	E	X	ES	X	1	X		Small Page

⁽¹⁾ See [Table 15-34](#) for endianness limitations.

M = Mixed region: 0 = Page-based endianness, 1 = Access-based endianness

E = Endianness: 0 = Little-endian, 1 = Big-endian (endianness is locked on little endian)

ES = Element Size: 00 = 8-bit, 01= 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

15.3.3.3.2 Small Page Translation Summary

[Figure 15-14](#) summarizes the translation process for small pages.

Figure 15-14. Small Page Translation Summary

MMU-014

15.3.3.3.3 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page. This is shown in [Figure 15-15](#).

Figure 15-15. Large Page Translation Summary

MMU-015

15.3.4 Translation Lookaside Buffer

Translating virtual to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first n TLB entries, where $n < \text{Total Number } N \text{ of TLB Entries}$, can be protected (locked) against being overwritten by setting the TLB base pointer to n . When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. [Figure 15-16](#) shows an example of TLB with N TLB entries (ranging from 0 to $N-1$). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

NOTE: The last TLB entry (Entry $N-1$, where $N = 8$ for the camera MMU and $N = 32$ for the IVA2.2 MMU) always remains unprotected.

Figure 15-16. TLB Entry Lock Mechanism

The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

15.3.4.1 TLB Entry Format

TLB entries consist of two parts:

- The CAM part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the [MMU_CAM](#) register table for more details.
- The RAM part contains the address translation that belongs to the virtual address tag as well as the endianness, element size, and mixed parameters described in [Section 15.3.3.2](#). See the [MMU_RAM](#) register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is when [MMU_GFLUSH\[0\]](#) GLOBALFLUSH is set to 1. Preserved entries must be deleted manually. [Section 15.3.3.2](#) describes the procedure to delete TLB entries.

[Figure 15-17](#) shows the TLB entry structure.

Figure 15-17. TLB Entry Structure

MMU-017

15.3.5 MMU Error Handling

The following types of faults can occur:

- TLB miss with table walker disabled
No translation is found for the virtual address required. If the hardware table walker is disabled, a fault is generated.
- Translation fault
No translation is found for the virtual address required (TLB miss). The table walker is enabled but a page table entry does not exist for the given virtual address.
- Table walk fault
A table walk results in a memory read error.
- Multi-hit fault
More than one valid entry exists in the TLB for the given virtual address.

When a fault occurs and its corresponding interrupt is enabled, an interrupt is signaled to the MPU. The interrupt service routine (ISR) is then responsible for fault recovery. The requestor is stalled by the MMU while the fault is handled. For example, for a TLB miss, the ISR might load the missing entry into the TLB.

The ISR can determine the cause of the fault interrupt by reading the MMU_n.[MMU_IRQSTATUS](#) register. The virtual address that caused the fault can be determined by reading the MMU_n.[MMU_FAULT_AD](#) register.

In the case of a TLB miss, the MMU continues servicing the request as soon as a valid TLB entry is written. In the case of a translation fault, table walk fault, or multi-hit fault, the ISR first addresses the cause of the fault and then releases the MMU by writing to the interrupt status register. The MMU then continues servicing the request.

15.3.6 MMU Instance Design Parameters

The various MMU instances have different design parameters, most notably the size of the virtual address space and the number of TLB entries. [Table 15-7](#) shows the correspondence between the MMU instances and the design parameters.

Table 15-7. Design Parameters of the MMU Instances

MMU Instance	Virtual Address Space	TLB Entries
MMU1 (camera MMU)	4GB	8 entries
MMU2 (IVA2.2 MMU)	4GB	32 entries

15.4 MMU Basic Programming Model

MMU instances handle translation from virtual into physical addresses. Virtual addresses are issued by the Camera or the IVA2.2 subsystems to the MMU, which converts them into physical addresses. These physical addresses correspond to actual memory resource. Refer to [Chapter 2, Memory Mapping](#) for more information on the device memory mapping.

MMU instances can be used dynamically or statically, in other words, MMU can be managed by the MPU software or configured directly.

An MMU is configured dynamically when a software subroutine writes translation tables into the appropriate physical memory space. Translation tables are most likely stored in external SDRAM (see SMS, [Section 10.2.4.1, SDRAM Memory Scheduler](#), for more details). They are automatically written by the MPU OS (Symbian™, Linux®,...). Operating System may limit the memory section size to page or sections. A MPU memory management software treats all information concerning addressing. Sub-set tables can be copied into external SDRAM to automatically create a given MMU translation table. Features such as mixed region, endianness, element size are then overwritten in SDRAM to match one's need and customize Camera or IVA2.2 subsystems' need (8-bit exchange in little-endian format for example). Note that 16MB sections and 64KB page table entries must be duplicated 16 times with the same content in translation tables. This process avoids a second read operation when an access points to another element than first one in the table. If they are not copied the MMU will behave in an unpredictable way.

When an MMU is configured statically, translation tables are not used, and TLB entries are written directly by the programmer.

[Figure 15-18](#) shows the configuration strategies: static, dynamic and mixed use of MMU.

Figure 15-18. MMU Configuration Strategies

MMU-018

MMU components must be set up before the MMU can be used for address translation. The following steps are required:

- Initialize translation tables and the table walker logic if translation tables are used.
- Write TLB entries if required.
- Enable MMU.

Next paragraph explains how to configure the IVA2.2 MMU by directly writing the entries in the Translation Look-aside Buffer (TLB). The focus of this example is to explain the required configuration steps rather than to provide the most efficient implementation.

15.4.1 Writing TLB Entries Statically

This example deals with predefined translation strategy, that is, entries are “statically” written in the TLB.

This method avoids the need to write Translation tables in memory and is commonly used for relatively small address spaces. It ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten. To setup the MMU follow those steps:

1. Reset MMU: write **MMU_SYSCONFIG[1]** SOFTRESET = 1 and wait for the system reset completion by polling **MMU_SYSSTATUS[0]** RESETDONE until it is equal to 1.
2. Set **MMU_SYSCONFIG[0]** AUTOIDLE bit to enable power saving via automatic interface clock gating.

After reset the Table walking logic remain disabled (**MMU_CRTL[2]** TWLENABLE = 0), the TLB is empty and the victim pointer points to the first TLB entry, Entry 0 (**MMU_LOCK[8:4]** CURRENTVICTIM at 0).

To initialize a TLB entry, follow those steps:

3. Load the Virtual Address (VATAG), the preserved (P=1) and valid (V=1) bits and the page size (small

- or large page, section, supersection) into **MMU_CAM** register.
4. Load the Physical Address (PHYSICALADDRESS), the endianness (ENDIANNESS = 0), element size (ELEMENTSIZE) and mixed page attributes bits (MIXED) into **MMU_RAM** register.
 5. Specify the TLB entry you want to write by setting the **MMU_LOCK[8:4]** CURRENTVICTIM pointer. Start with TLB Entry 0 and increment this pointer for each subsequent entry you want to write.
 6. Load the specified entry in the TLB by setting **MMU_LD_TLB[0]** LDTLBITEM = 1.
 7. Repeat steps 3 to 6 for all entries you want to write.

Remember to increment the **MMU_LOCK[8:4]** CURRENTVICTIM pointer with each entry you are writing. To prevent replacement of TLB entries see [Section 15.4.1.1, Protecting TLB Entries](#).

To enable error handling when more than one valid entry exists in the TLB for the given virtual address or when no translation is found for the virtual address required (with the Table walking logic disabled):

8. Enable Multi-hit fault and TLB miss with table walker disabled interrupts by writing 1 in **MMU_IRQENABLE[4]** MULTIHITFAULT and **MMU_IRQENABLE[0]** TLBMISS.
9. To determine the cause of the fault interrupt the interrupt service routine (ISR) can read corresponding **MMU_IRQSTATUS** bits. The virtual address that caused the fault can be determined by reading **MMU_FAULT_AD**.

NOTE: MMU errors result in a memory stall; the MMU will not process any request until the cause of the error has been addressed.

To enable memory translations enable MMU (virtual addresses are treated as physical addresses when MMU is disabled):

10. Set **MMU_CNTL[1]** MMUENABLE = 1 to enable memory translations enable the MMU (virtual addresses are treated as physical addresses when the MMU is disabled).

15.4.1.1 Protecting TLB Entries

The first n TLB entries (with $n <$ total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval via the table walking process.

The entry protection mechanism is shown in [Figure 15-16](#). To protect the first n TLB entries, set the MMU1.**MMU_LOCK[12:10]** BASEVALUE bit field for the camera MMU (MMU2.**MMU_LOCK[14:10]** BASEVALUE field for the IVA2.2 MMU) to n .

15.4.1.2 Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, i.e., TLB entries that were written with the preserved bit set to zero, can be deleted by invoking a TLB flush. Such a TLB flush is invoked by setting the MMU.**GFLUSH[0]** GLOBALFLUSH bit.

Individual TLB entries can be flushed, regardless of the preserved bit setting, by specifying its virtual address in the MMU.**MMU_CAM** register and setting the MMU.**MMU_FLUSH_ENTRY[0]** FLUSHENTRY bit.

The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

15.4.1.3 Reading TLB Entries

TLB entries can be read by you to determine the TLB content at runtime. In doing so, the TLB entry number is specified by setting the MMU.**MMU_LOCK[8:4]** CURRENTVICTIM pointer. CAM and RAM parts of the TLB entry can then be read in the MMU.**MMU_READ_CAM** and MMU.**MMU_READ_RAM** registers, respectively.

15.4.2 Programming the MMU Dynamically

When translation tables are used for MMU address translation they must be properly set up and the table walking logic must be enabled.

The following page sizes are supported:

- Supersection: 16M bytes
- Section: 1M byte
- Large page: 64K bytes
- Small page: 4K bytes

The memory location of these sections or pages (the Physical Address) is found by reading the Translation Table Hierarchy using a combination of the Virtual Address and the Translation Table Base address. [Figure 15-19](#) illustrates the MMUn translation table hierarchy, with first-level descriptors (L1D) and second-level descriptors (L2D).

Figure 15-19. MMUn Translation Table Hierarchy

MMU-019

The first step is to build translation tables (first- and second-level translation tables depending on translation strategy) and place them into memory.

The start address of translation tables must always be aligned according to their size. For example, a 4096-entry first-level translation table must be aligned on a 16KB boundary (4096 Entries * 4 bytes = 16KB); that is, the lower 14 bits of the translation table start address (MMU_TTB[13:0]) must be 0. For more details, see [Section 15.3.3.2](#).

After the translation tables have been written to memory the translation table base address (that is, the most significant bits of the first-level translation table start address) must be set. This is done using the MMU_n.MMU_TTB[31:7] TTBADDRESS bit field. See [Section 15.5](#) for a complete description of the MMU control registers.

Once the translation tables have been written to memory and the translation table base is set, the table walking logic can be enabled. This is done by setting the MMU_n.MMU_CNTL[2] TWLENABLE bit.

15.4.2.1 Programming the MMU Using First- and Second-Level Translation Tables

Translation tables must be set up and written in memory. Each TLB entry contains a memory page size: 1MB section or 16MB supersection. When the page size is smaller, 4KB or 64KB, second-level translation tables are necessary. To set up the MMU, follow the same steps as in the previous example but write the first- and second-level descriptors in physical memory.

The first-level translation table describes the translation properties for 1MB sections. To describe a 4-GB address range with 1-MB sections, 4096 32-bit entries (so-called first-level descriptors) are required. The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table (that is, at least the last 14 address bits must be 0). The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. [Figure 15-20](#) through [Figure 15-23](#) shows how the physical address is built from the virtual address as a function of the page sizes and hierarchy.

15.5 MMU Register Manual

The MMU1 (camera ISP MMU) and MMU2 (IVA2.2 MMU) instances are programmed using two identical sets of configuration registers. [Table 15-8](#) lists the base address of each register set.

Table 15-8. MMU Instance Summary

MMU Instance	Base Address	Size
MMU1 (Camera MMU)	0x480B D400	256 bytes
MMU2 (IVA2.2 MMU)	0x5D00 0000	256 bytes

NOTE: The MPU MMU is configured using register CP15. For more information, see the public ARM Cortex-A8 TRM.

15.5.1 Register Mapping Summary

Each MMU instance (except the MPU MMU) is programmed using a set of 18 configuration registers. [Table 15-9](#) lists these registers and their access type, access size, and offset against their respective base address.

NOTE: The registers and their bit fields in this set are identical for the two instances except the MMU_n.[MMU_LOCK](#) register, which has bit fields for the MMU1 (camera ISP MMU) that are different from the MMU2 (IVA2.2 MMU).

CAUTION

MMU2 instance (IVA2.2 MMU) registers are limited to 32-bit data accesses. Data access of 16 bits and 8 bits are not allowed and can corrupt register content.

Table 15-9. MMU Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	MMU1 (Camera MMU) Physical Address	MMU2 (IVA2.2 MMU) Physical Address

This chapter describes the timer modules for the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
16.1 Timers Overview	2718
16.2 General-Purpose Timers	2719
16.3 General-Purpose Timers Register Manual	2740
16.4 Watchdog Timers	2766

16.6 32-kHz Synchronized Timer	2783
16.7 32-kHz Sync Timer Register Manual	2785

16.1 Timers Overview

The device includes several types of timers used by the system software, including 11 general-purpose timers (GP timers), two watchdog timers (WDTs), and a 32-kHz synchronized timer. [Figure 16-1](#) shows the counters in the device in a high-level block diagram.

Figure 16-1. Timers

timers-027

The 2 WDTs are clocked with 32-kHz clocks. The 32-kHz synchronized timer, which is reset only at power up, provides the operating system with a stable timing source that stores the relative time since the last power cycle of the product. Finally, 11 GP timers, which are useful simply as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

16.2 General-Purpose Timers

16.2.1 GP Timers Overview

The device has 11 GP timers: GPTIMER1 through GPTIMER11.

Each timer can be clocked from either the system clock (12, 13, 16.8, 19.2, 26, or 38.4 MHz) or the 32-kHz clock. The selection of the clock source is made at the power, reset, clock management (PRCM) module level. For more information, see [Section 16.2.3.1, Clocking, Reset, and Power-Management Scheme](#).

GPTIMER1 has its GPT1_EVENT_CAPTURE pin tied to the 32-kHz clock and can be used to gauge the system clock input; it detects its frequency among 12, 13, 16.8, 19.2, 26, or 38.4 MHz.

Each timer can provide an interrupt to the microprocessor unit (MPU) subsystem. In addition, GPTIMER5 through GPTIMER8 also have interrupts connected to the IVA2.2 subsystem.

GPTIMER1, GPTIMER2, and GPTIMER10 include specific functions to generate accurate tick interrupts to the operating system. GPTIMER8 through GPTIMER11 are connected to external pins by their PWM output or their event capture input pin (for external timer triggering). [Figure 16-2](#) shows an overview of the GP timers.

Figure 16-2. GP Timers Overview

16.2.1.1 GP Timers Features

The following are the main features of the GP timers controllers:

- L4 slave interface support:
 - 32-bit data bus width
 - 32-/16-bit access supported
 - 8-bit access not supported
 - 10-bit address bus width
 - Burst mode not supported
 - Software-selectable nonposted or posted write/read internal resynchronization modes
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source (2^n with $n = [0:8]$)
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated output signal for general-purpose using GPTi_GPOCFG signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32,768 Hz functional clock generated (only GPTIMER1, GPTIMER2, and GPTIMER10)

16.2.2 GP Timers Environment

16.2.2.1 GP Timers External System Interface

Four of the 11 GP timers can send or receive stimulus to/from the external (off-chip) system. In the device, however, only GPTIMER8 through GPTIMER11 are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count. GPTIMER1 is also configured to receive an event trigger input (GPT1_EVENT_CAPTURE) tied to the internal 32-kHz clock. This event signal gauges the system clock input; it detects its frequency among 12, 13, 16.8, 19.2, 26, or 38.4 MHz.

[Figure 16-3](#) shows the external system interface for the GP timers, and [Table 16-1](#) describes the GP timer inputs and outputs.

NOTE: Software must ensure that mux mode is configured to select the gpt_x_pwm_evt (where $x = 8$ to 11) signal on only one pad. Other pads on which the same signal is multiplexed must be configured in safe mode or non-gptimer mode to avoid two different pads driving the same signal.

For more information about the gpt_8_pwm_evt through gpt11_pwm_evt I/O pad configuration, see [Chapter 13, System Control Module](#).

Figure 16-3. GP Timers External System Interface

timers-003

Table 16-1. Input/Output Description

Pin Name	Type ⁽¹⁾	Reset Value	Signal Name	Description
gpt8_pwm_evt	I/O	0	GPT8_EVENT_CAPTURE GPT8_PWM_OUT	GPTIMER8 trigger input/ PWM output
gpt9_pwm_evt	I/O	0	GPT9_EVENT_CAPTURE GPT9_PWM_OUT	GPTIMER9 trigger input/ PWM output
gpt10_pwm_evt	I/O	0	GPT10_EVENT_CAPTURE GPT10_PWM_OUT	GPTIMER10 trigger input/ PWM output
gpt11_pwm_evt	I/O	0	GPT11_EVENT_CAPTURE GPT11_PWM_OUT	GPTIMER11 trigger input/ PWM output

⁽¹⁾ When configured for that function; I = input, O = output

NOTE: The event trigger input (GPTi_EVENT_CAPTURE) for GPTIMER2 through GPTIMER7 is internally tied low, and the PWM output (GPTi_PWM_OUT) is not connected.

16.2.3 GP Timers Integration

Figure 16-4 shows the GP timer integration in the device.

Figure 16-4. GP Timer Integration

16.2.3.1 Clocking, Reset, and Power-Management Scheme

16.2.3.1.1 Clock Management

There are two clock domains in the GP timers:

- Functional clock domain: GPTi_FCLK is the GP timer functional clock. It is used to clock the GP timer internal logic.
- Interface clock domain: GPTi_ICLK is the GP timer interface clock. It is used to synchronize the GP timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to GPTi_ICLK.

Table 16-2 lists the source clocks for each GP timer in the device. For more information on clock control and domains, see [Chapter 3, Power, Reset, and Clock Management](#).

Table 16-2. Clock, Power, and Reset Domains for GP Timers

Timer	Interface Clock	Functional Clock	Power Domain
GPTIMER1	WKUP_L4_ICLK	GPT1_FCLK	WKUP
GPTIMER2 through GPTIMER9	PER_L4_ICLK	GPTx_ALWON_FCLK (x = 2 through 9)	PER
GPTIMER10 and 11	CORE_L4_ICLK	GPTx_FCLK (x = 10 or 11)	CORE

GP timers can be selected as the source of GPT_i_FCLK (32-kHz clock or 12, 13, 16.8, 19.2, 26, or 38.4 MHz) at the PRCM level in the corresponding registers. For more information, see [Chapter 3, Power, Reset, and Clock Management](#). **Table 16-3** lists the GP timer PRCM clock selection bits.

Table 16-3. GP Timer PRCM Clock Selection Bits

Name	Associated PRCM Clock Output	Selection Bit
GPT1_FCLK	GPT1_FCLK	PRCM.CM_CLKSEL_WKUP[0] CLKSEL_GPT1
GPT[2:9]_FCLK	GPT[2:9]_ALWON_FCLK	PRCM.CM_CLKSEL_PER [0:7] CLKSEL_GPT[2:9]
GPT10_FCLK	GPT10_FCLK	PRCM.CM_CLKSEL_CORE [6] CLKSEL_GPT10
GPT11_FCLK	GPT11_FCLK	PRCM.CM_CLKSEL_CORE [7] CLKSEL_GPT11

From a global system power-management perspective, when one or both of the GP timer clocks is no longer required, the GP timers can be deactivated at the PRCM level in the corresponding registers. **Table 16-4** lists the GP timer PRCM clock control bits.

Table 16-4. GP Timer PRCM Clock Control Bits

Name	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
GPT1_FCLK	GPT1_FCLK	PRCM.CM_FCLKEN_WKUP[0] EN_GPT1 bit	N/A
GPT[2:9]_FCLK	GPT[2:9]_ALWON_FCLK	PRCM.CM_FCLKEN_PER [3:10] EN_GPT[2:9] bit	N/A
GPT10_FCLK	GPT10_FCLK	PRCM.CM_FCLKEN1_CORE [11] EN_GPT10 bit	N/A
GPT11_FCLK	GPT11_FCLK	PRCM.CM_FCLKEN1_CORE [12] EN_GPT11 bit	N/A
GPT1_ICLK	WKUP_L4_ICLK	PRCM.CM_ICLKEN_WKUP[0] EN_GPT1 bit	PRCM.CM_AUTOIDLE_WKUP[0] AUTO_GPT1 bit
GPT[2:9]_ICLK	PER_L4_ICLK	PRCM.CM_ICLKEN_PER[3:10] EN_GPT[2:9] bit	PRCM.CM_AUTOIDLE_PER[3:10] AUTO_GPT[2:9] bit
GPT10_ICLK	CORE_L4_ICLK	PRCM.CM_ICLKEN1_CORE[11] EN_GPT10 bit	PRCM.CM_AUTOIDLE1_CORE[11] AUTO_GPT10 bit
GPT11_ICLK		PRCM.CM_ICLKEN1_CORE[12] EN_GPT11 bit	PRCM.CM_AUTOIDLE1_CORE[12] AUTO_GPT11 bit

NOTE:

- The PRCM function clock outputs are gated at the PRCM level, assuming all the modules that share it are disabled in the corresponding register. Disabling GP timers is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see [Chapter 3, Power, Reset, and Clock Management](#).
- The PRCM interface clock outputs are gated at the PRCM level, assuming all the modules that share it are disabled in the corresponding register. Disabling GP timers is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see [Chapter 3, Power, Reset, and Clock Management](#).
- The PRCM AUTOIDLE bits are used to link/unlink the GP timers from the clock domain transitions related to the GPTi_ICLK clocks.
- For further details about source clock gating and domain transitions, see [Chapter 3, Power, Reset, and Clock Management](#).

GP timer modules also have an internal bit, GPTi.[TIOCP_CFG\[0\]](#) AUTOIDLE. The GP timer AUTOIDLE bit is used to apply an internal interface clock gating strategy.

At the PRCM level, when all conditions to shut off the PRCM functional or interface output clocks are met (see [Chapter 3, Power, Reset, and Clock Management](#), for details), the PRCM automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the GPTi.[TIOCP_CFG\[4:3\]](#) IDLEMODE bit. [Table 16-5](#) lists the IDLEMODE settings and the related acknowledgment modes.

Table 16-5. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach for efficient system power management.
11	Reserved	

When configured in smart-idle mode, the GP timer also offers an additional granularity on GPTi_FCLK and GPTi_ICLK gating. The GPTi.[TIOCP_CFG\[9:8\]](#) CLOCKACTIVITY bit field is used to determine which clock will be shut down (GPTi_FCLK, GPTi_ICLK, neither of them, or both of them).

The CLOCKACTIVITY setting is used internally to the GP timer to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request will be tested. For example, if GPTi_FCLK is not to be shut down on a PRCM IDLE request, the GP timer considers only GPTi_ICLK and the associated pending activities before acknowledging the request.

Some GP timer features are associated with GPTi_ICLK and others are associated with GPTi_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that will remain active are always enabled, even if the GP timer acknowledges an IDLE request.

Table 16-6 lists the CLOCKACTIVITY settings and the associated features.

Table 16-6. CLOCKACTIVITY Settings

CLOCKACTIVITY Value	GPTi_ICLK Effects	GPTi_FCLK Effects	Description	Associated Features
00	OFF	OFF	Both GPTi_ICLK and GPTi_FCLK are considered for generating the acknowledge. This setting also means both GPTi_FCLK and GPTi_ICLK are likely to be shut down on PRCM IDLE request.	The idle acknowledge signal is asserted when there are no pending activities on the functional clock domain (improved latency in assertion of idle acknowledge). The wake-up capability of the GP timer is disabled.
01	ON	OFF	GPTi_ICLK is not shut down on PRCM IDLE request; only GPTi_FCLK is affected.	
10	OFF	ON	GPTi_FCLK is not shut down on PRCM IDLE request; only GPTi_ICLK is affected.	
11	ON	ON	None of the clocks are shut down. Therefore, the GP timer can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks.	The idle acknowledge signal is asserted when there are no pending activities on the interface clock domain, without evaluating the pending activities on the functional clock domain (the GP timer enters into sleep mode, and if a pending interrupt event is finished during idle mode, the wake-up signal is asserted). The wake-up signal is enabled.

CAUTION

The PRCM module does *not* have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the GP timer CLOCKACTIVITY and the PRCM functional clock and interface clock control bits. If the GP timer is disabled in both CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the GP timer clocks. This can lead to unpredictable behavior.

16.2.3.1.2 Wake-Up Capability

If the GPTi.TIOCP_CFG[4:3] IDLEMODE field sets the smart-idle mode, the timer module evaluates its internal capability to have the interface clock switched off. When there is no more internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters into sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the GPTi.TIOCP_CFG[2] ENAWAKEUP bit enables the timer wake-up capability.

Figure 16-5 shows the wake-up request generation. For more information on the GP timer clock control, see Section 16.2.3.1.1, *Clock Management*.

Figure 16-5. Wake-Up Request Generation

timers-005

The timer wake-up enable register (GPTi.TWER) allows masking the expected source of the wake-up event that generates a wake-up request. The GPTi.TWER register is programmed synchronously with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (GPTi.TCRR), a timer match (the compare result of GPTi.TCRR and GPTi.TMAR matches the counter value), and a timer capture (an external pulse transition of the correct polarity is detected on the GPTi.EVENT_CAPTURE).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (GPTi.TISR). The pending wake-up event is reset when the set status bit is overwritten by 1.

NOTE: The status bit must be reset to re-enter idle mode.

16.2.3.1.3 Reset and Power Management

GPTIMER1 belongs to the WKUP power domain. As part of that domain, this GP timer is sensitive to a WKUP_RST signal issued by the PRCM module. For further details about the WKUP power domain implementation and the WKUP_RST signal, see [Chapter 3, Power, Reset, and Clock Management](#).

GPTIMER2 through GPTIMER9 belong to the PER power domain. As part of that domain, these GP timers are sensitive to a PER_RST signal issued by the PRCM module. For further details about the PER power domain implementation and the PER_RST signal, see [Chapter 3, Power, Reset, and Clock Management](#).

GPTIMER10 and GPTIMER11 belong to the CORE power domain. As part of that domain, these GP timers are sensitive to a CORE_RST signal issued by the PRCM module. For further details about the CORE power domain implementation and the CORE_RST signal, see [Chapter 3, Power, Reset, and Clock Management](#).

16.2.3.2 Software Reset

Two bit fields (GPTi.TIOCP_CFG[1] SOFTRESET and GPTi.TSICR[1] SFT) can generate a software reset of the GP timer. For both of these bits, all read accesses return 0.

The GPTi.TIOCP_CFG[1] SOFTRESET bit allows resetting the functional and interface domains. The GPTi.TSICR[1] SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the GPTi.TISTAT[0] RESETDONE bit. This bit field monitors the internal reset status.

16.2.3.3 GP Timer Interrupts

Table 16-7 lists the interrupt mapping from the 12 GP timers to the three internal processors.

Table 16-7. Timer Interrupt Names and Processor IRQ Mapping

Timer	Interrupt Name	Mapping	Comments
GPTIMER 1	GPT1_IRQ	M_IRQ_37	GPTIMER1 interrupt to MPU
GPTIMER2	GPT2_IRQ	M_IRQ_38	GPTIMER2 interrupt to MPU
GPTIMER3	GPT3_IRQ	M_IRQ_39	GPTIMER3 interrupt to MPU
GPTIMER4	GPT4_IRQ	M_IRQ_40	GPTIMER4 interrupt to MPU
GPTIMER5	GPT5_IRQ	M_IRQ_41	GPTIMER5 interrupt to MPU
		IVA2_IRQ[6]	GPTIMER5 interrupt to IVA2.2
GPTIMER6	GPT6_IRQ	M_IRQ_42	GPTIMER6 interrupt to MPU
		IVA2_IRQ[7]	GPTIMER6 interrupt to IVA2.2
		MD_IRQ_6	GPTIMER6 interrupt to modem subsystem (D2D)
GPTIMER7	GPT7_IRQ	M_IRQ_43	GPTIMER7 interrupt to MPU
		IVA2_IRQ[8]	GPTIMER7 interrupt to IVA2.2
		MD_IRQ_7	GPTIMER7 interrupt to modem subsystem (D2D)
GPTIMER8	GPT8_IRQ	M_IRQ_44	GPTIMER8 interrupt to MPU
		IVA2_IRQ[9]	GPTIMER8 interrupt to IVA2.2
		MD_IRQ_8	GPTIMER8 interrupt to modem subsystem (D2D)
GPTIMER9	GPT9_IRQ	M_IRQ_45	GPTIMER9 interrupt to MPU
		MD_IRQ_9	GPTIMER9 interrupt to modem subsystem (D2D)
GPTIMER10	GPT10_IRQ	M_IRQ_46	GPTIMER10 interrupt to MPU
GPTIMER11	GPT11_IRQ	M_IRQ_47	GPTIMER11 interrupt to MPU

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled/disabled in the interrupt enable register (GPTi.TIER). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (GPTi.TISR). The pending interrupt event is reset when the set status bit is overwritten by a1.

16.2.4 GP Timers Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition type. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line. Each internal interrupt source can be independently enabled/disabled with a dedicated bit of the GPTi.[TIER](#) register for the interrupt features and a dedicated bit of the GPTi.[TWER](#) register for the wakeup. In addition, GPTIMER1, GPTIMER2, and GPTIMER10 have implemented a mechanism to generate an accurate tick interrupt.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

Selection of the input clock source is done in the registers in the PRCM configuration (see [Section 16.2.1, GP Timers Overview](#)).

Each GP timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

By default, after core reset, the capture and compare modes are disabled.

16.2.4.1 GP Timers Block Diagram

[Figure 16-6](#) shows the block diagram of common GP timers, and [Figure 16-7](#) shows the block diagram of GP timers with 1-ms tick generation module.

Figure 16-6. Block Diagram of GPTIMER3 through GPTIMER9 and GPTIMER11

timers-006

Figure 16-7. Block Diagram of GPTIMER1, GPTIMER2, and GPTIMER10

timers-007

16.2.4.2 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (GPTi.TCLR[0] ST bit). The timer counter register (GPTi.TCRR) can be loaded when stopped or on-the-fly (while counting). GPTn.TCRR can be loaded directly by a GPTi.TCRR write access with a new timer value. The GPTi.TCRR register can also be loaded with the value held in the timer load register GPTi.TLDR by a trigger register (GPTi.TTGR) write access. The GPTi.TCRR loading is done regardless of the GPTi.TTGR written value. The timer counter register GPTi.TCRR value can be read when stopped or captured on-the-fly by a GPTi.TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the GPTi.TCLR[1] AR bit set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the GPTi.TCLR[1] AR bit set to 1), the GPTi.TCRR register is reloaded with the timer load register (GPTi.TLDR) value after a counting overflow occurs.

CAUTION

Do not put the overflow value (0xFFFFFFFF) in the GPTi.TLDR register because it can lead to undesired results.

An interrupt can be issued on overflow if the overflow interrupt enable bit is set in the timer interrupt enable register (GPTi.TIER[1] OVF_IT_ENA bit set to 1), the interrupt is enabled after $10 * \text{GPTi.} \text{ICLK}$ clock cycles. A dedicated output pin (timer PWM) can be programmed in GPTi.TCLR[12] through GPTi.TCLR[11:10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The GPTi.TCLR[12] PT bit selects pulse/toggle modulation (GPTi.TCLR[11:10] TRG bit field select trigger mode).

Figure 16-8 shows the GPTi.TCRR timing value.

Figure 16-8. GPTi.TCRR Timing Value

16.2.4.2.1 1-ms Tick Generation (Only GPTIMER1, GPTIMER2, and GPTIMER10)

Because the timer input clock is 32,768 Hz, the interrupt period is not exactly 1 ms. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations to the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32,768 Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. Refer to Figure 16-9.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (GPTi.TPIR[31:0] POSITIVE_INC_VALUE bit field) and the timer negative increment register (GPTi.TNIR[31:0] NEGATIVE_INC_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Figure 16-9. Block Diagram of the 1-ms Tick Module

timers-009

The GPTi.TPIR, GPTi.TNIR, and GPTi.TCVR registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (GPTi.TCRR[31:0] TIMER_COUNTER bit field) is the value of the GPTi.TLDR[31:0] LOAD_VALUE bit field (period less than 1 ms) or the value of GPTi.TLDR[31:0] LOAD_VALUE - 1 (period greater than 1 ms).

Table 16-8 lists the value loaded in the GPTi.TCRR register according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value, MSB = 1: Negative value

Table 16-8. Value Loaded in GPTi.TCRR to Generate 1-ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	Value of GPTi.TCRR Register
0	0	0	GPTi.TLDR[31:0] LOAD_VALUE bit field
0	0	1	GPTi.TLDR[31:0] LOAD_VALUE bit field
0	1	0	GPTi.TLDR[31:0] LOAD_VALUE bit field
0	1	1	GPTi.TLDR[31:0] LOAD_VALUE - 1
1	0	0	N/A
1	0	1	N/A
1	1	0	GPTi.TLDR[31:0] LOAD_VALUE - 1
1	1	1	GPTi.TLDR[31:0] LOAD_VALUE - 1

The values of the GPTi.TPIR and GPTi.TNIR registers are calculated using the following formula:

- Positive increment value = ((INTEGER[Fclk * Ttick] + 1) * 1e6) - (Fclk * Ttick * 1e6)
- Negative increment value = (INTEGER[Fclk * Ttick] * 1e6) - (Fclk * Ttick * 1e6)

NOTE: Fclk clock frequency (kHz)

Ttick tick period (ms)

The timer overflow counter register (GPTi.TOCR) and the timer overflow wrapping register (GPTi.TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit TOCR register. When the 24-bit TOCR register values match the value in the 24-bit TOWR register and the timer overflow is asserted, the TOCR register is reset and an interrupt is generated to the TISR register.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of GPTIMER1, GPTIMER2, and GPTIMER10 remain unchanged.

For 1-ms tick with a 32,768-Hz clock:

- GPTi.TPIR[31:0] POSITIVE_INC_VALUE = 232000
- GPTi.TNIR[31:0] NEGATIVE_INC_VALUE = -768000
- GPTi.TLDR[31:0] LOAD_VALUE = 0xFFFFFFF0

NOTE: Any value of the tick period can be generated with the appropriate value of the GPTi.TPIR, GPTi.TNIR, and GPTi.TLDR registers.

By default, the GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR registers and the associated logic are in reset mode (all 0s) and have no action on the programming model.

16.2.4.3 Capture Mode Functionality

When a transition is detected on the module input pin (EVENT_CAPTURE), the timer value in the GPTi.TCRR register can be captured and saved in the GPTi.TCAR1 or GPTi.TCAR2 register function of the mode selected in the GPTi.TCLR[13] CAPT_MODE bit. The edge detection circuitry monitors transitions on the input pin (EVENT_CAPTURE).

The rising edge, falling edge, or both, can be selected in the GPTi.TCLR[9:8] TCM field to trigger the timer counter capture. The module sets the GPTi.TISR[2] TCAR_IT_FLAG bit when an active edge is detected, and at the same time, the counter value GPTi.TCRR is stored in timer capture register GPTi.TCAR1 or GPTi.TCAR2, as follows:

- If the GPTi.TCLR[13] CAPT_MODE bit is 0, then on the first enabled capture event the value of the counter register is saved in the GPTi.TCAR1 register, and all the next events are ignored (no update on the GPTi.TCAR1 register and no interrupt triggering) until the detection logic is reset or the GPTi.TISR[2] TCAR_IT_FLAG bit is cleared by writing 1 in it.
- If the GPTi.TCLR[13] CAPT_MODE bit is 1, then on the first enabled capture event the value of the counter register is saved in the GPTi.TCAR1 register, and on the second enabled capture event, the value of the counter register is saved in the GPTi.TCAR2 register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on GPTi.TCAR1/GPTi.TCAR2 and no interrupt triggering) until the detection logic is reset or GPTi.TISR[2] TCAR_IT_FLAG bit is cleared by writing 1 in it. This mechanism is useful for period calculation of a clock, if that clock is connected to the EVENT_CAPTURE input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served the GPTi.TISR[2] TCAR_IT_FLAG bit (previously 1) is cleared by writing 1 to it or when the edge detection mode bits (the GPTi.TCLR[9:8] TCM bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (EVENT_CAPTURE). An input negative or positive pulse can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt enable bit is set in the GPTi.TIER[2] TCAR_IT_ENA bit. See the examples in Figure 16-10 and Figure 16-11.

In Figure 16-10, the GPTi.TCLR[9:8] TCM value is 0b01, and GPTi.TCLR[13] CAPT_MODE is 0. Only the rising edge of EVENT_CAPTURE triggers a capture in the GPTi.TCAR1 and GPTi.TCAR2 registers, and only the GPTi.TCAR1 register updates.

Figure 16-10. Capture Wave Example for GPTi.TCLR[13] CAPT_MODE = 0

In Figure 16-11, the GPTi.TCLR[9:8] TCM value is 0b01, and GPTi.TCLR[13] CAPT_MODE is 1. Only the rising edge of EVENT_CAPTURE triggers a capture in the GPTi.TCAR1 register on the first enabled event, and the GPTi.TCAR2 register updates on the second enabled event.

Figure 16-11. Capture Wave Example for GPTi.TCLR[13] CAPT_MODE = 1

16.2.4.4 Compare Mode Functionality

When the compare enable register GPTi.TCLR[6] CE bit is set to 1, the timer value (GPTi.TCRR[31:0] TIMER_COUNTER field) is continuously compared to the value held in the timer match register (GPTi.TMAR). The GPTi.TMAR[31:0] COMPARE_VALUE value can be loaded at any time (timer counting or stopped). When the GPTi.TCRR and the GPTi.TMAR values match, an interrupt is issued, if the GPTi.TIER[0] MAT_IT_ENA bit is set.

The dedicated output pin (timer PWM) can be programmed in the GPTi.[TCLR\[12\]](#) PT bit through the GPTi.[TCLR\[11:10\]](#) TRG field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

16.2.4.5 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the GPTi.[TCLR\[5\]](#) PRE bit is set. The GPTi.[TCLR\[4:2\]](#) PTV field sets the second prescaler ratio. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

[Table 16-9](#) lists the prescaler/timer reload values versus contexts.

Table 16-9. Prescaler/Timer Reload Values Versus Contexts

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	GPTi. TLDR[31:0]
TCRR write	Reset	GPTi. TCRR[31:0]
TTGR write	Reset	GPTi. TLDR[31:0]
Stop	Reset	Frozen

16.2.4.6 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The GPTi.[TCLR\[11:10\]](#) TRG field determines on which register value the PWM pin toggles. Either overflow alone or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

CAUTION

In toggle mode when GPTi.[TCLR\[11:10\]](#) TRG = 0x2 (overflow and match), the first event that will toggle the PWM line is an overflow event. If a match event occurs first, it will not toggle the PWM line. [Figure 16-13](#) illustrates those.

The GPTi.[TCLR\[7\]](#) SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the GPTi.[TCLR\[11:10\]](#) TRG field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In [Figure 16-12](#), the internal overflow pulse is set each time (0xFFFF FFFF – GPTi.[TLDR\[31:0\]](#) LOAD_VALUE + 1) the value is reached, and the internal match pulse is set when the counter reaches the GPTi.[TMAR](#) register value. According to the value of the GPTi.[TCLR\[12\]](#) PT and GPTi.[TCLR\[11:10\]](#) TRG bits, the timer provides pulse or PWM event on the output pin (timer PWM).

The GPTi.[TLDR](#) and GPTi.[TMAR](#) registers must keep values smaller than the overflow value (0xFFFF FFFF) by at least two units. In case the PWM trigger events are both overflow and match, the difference between the values kept in the GPTi.[TMAR](#) register and the value in the GPTi.[TLDR](#) register must be at least two units. When match event is used, the compare mode GPTi.[TCLR\[6\]](#) CE bit must be set.

In [Figure 16-12](#), the GPTi.[TCLR\[7\]](#) SCPWM bit is set to 0. In [Figure 16-13](#), the GPTi.[TCLR\[7\]](#) SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (GPTi.[TCLR\[7\]](#) SCPWM bit).

Figure 16-12. Timing Diagram of PWM With GPTi.TCLR[7] SCPWM Bit = 0**Figure 16-13. Timing Diagram of PWM With GPTi.TCLR[7] SCPWM Bit = 1**

16.2.4.7 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (GPTi.TCLR[5] PRE bit and GPTi.TCLR[4:2] PTV field)
- Value loaded into the timer load register (GPTi.TLDR)

Table 16-10 lists prescaler clock ratio values.

Table 16-10. Prescaler Clock Ratio Values

GPTi.TCLR[5] PRE	GPTi.TCLR[4:2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32

Table 16-10. Prescaler Clock Ratio Values (continued)

GPTi.TCLR[5] PRE	GPTi.TCLR[4:2] PTV	Divisor (PS)
1	5	64
1	6	128
1	7	256

Thus, the timer overflow-rate is expressed as:

$$\text{OVF_Rate} = (0xFFFF FFFF - \text{GPTn.TLDR} + 1) * (\text{timer-functional clock period}) * \text{PS}$$

With $(\text{timer-functional clock period}) = 1 / (\text{timer-functional clock frequency})$ and $\text{PS} = 2^{(\text{PTV} + 1)}$ if prescaler is enabled, or $\text{PS} = 1$ if prescaler is disabled.

CAUTION

Internal resynchronization causes any write to the GPTn.TCLR[1] ST bit to have some latency before the register is updated:

2.5 * functional clock cycles write_GPTn.TCLR_latency 3.5 * functional clock cycles

Remember to take this latency into account whenever the timer must be started or stopped by a software change to the GPTn.TCLR[1] ST bit.

CAUTION

- In the non-PWM mode, GPTi.TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In the PWM mode, GPTi.TLDR must be maintained at less than or equal to 0xFFFF FFFD.

For example, with a timer clock input of 32 kHz and a GPTn.TCLR[5] PRE field equal to 0, the timer output period is as listed in [Table 16-11](#).

Table 16-11. Value and Corresponding Interrupt Period

GPTi.TLDR[31:0] LOAD_VALUE	Interrupt Period
0x0000 0000	39 h
0xFFFF 0000	2.1 s
0xFFFF FFF0	524 µs
0xFFFF FFFE	65.5 µs

16.2.5 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the GPTi.TIOCP_CFG[5] EMUFREE bit.

If the GPTi.TIOCP_CFG[5] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the GPTi.TIOCP_CFG[5] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (gpti_pwm_evt, where i = [8:11]) is internally synchronized on two timer-clock rising edges.

16.2.6 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration.

All registers are 32 bits wide, accessible through the L4 interface with 16-bit or 32-bit access (read/write).

Any 16-bit write access must be least-significant bit (LSB) first, and the second write access must be most-significant bit (MSB). Write operations to the GP timer registers (GPTi.TIDR, GPTi.TIOCP_CFG, GPTi.TISR, GPTi.TIER, GPTi.TWER, and GPTi.TSICR) can skip the MSB access if it is not necessary to update the 16 MSBs of the register.

Write operations to any functional register (GPTi.TCLR, GPTi.TCRR, GPTi.TLDR, GPTi.TTGR, and GPTi.TMAR, and GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR for GPTIMER1, GPTIMER2, and GPTIMER10) must be complete (the MSB must be written even if the MSB data is not used).

16.2.6.1 Writing to Timer Registers

The host uses the L4 interface to write the following registers synchronously with the timer interface clock:

- GPTi.TLDR
- GPTi.TCRR
- GPTi.TIER
- GPTi.TISR
- GPTi.TCLR
- GPTi.TIOCP_CFG
- GPTi.TWER
- GPTi.TTGR
- GPTi.TSICR
- GPTi.TMAR

GPTIMER1, GPTIMER2, and GPTIMER10 also have the following registers:

- GPTi.TPIR
- GPTi.TNIR
- GPTi.TCVR
- GPTi.TOCR
- GPTi.TOWR

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

16.2.6.1.1 Write Posting Synchronization Mode

This mode is used if the GPTi.TSICR[2] POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register (GPTi.TCLR, GPTi.TCRR, GPTi.TLDR, GPTi.TTGR, GPTi.TMAR, and GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR for GPTIMER1, GPTIMER2, and GPTIMER10). Therefore, the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later, because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the timer write-posted status register GPTi.TWPS. In this mode, it is mandatory that the software checks this status bit prior to any write access. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the timer counter register value synchronously with the L4 clock. Consequently, any read access to the timer counter register GPTi.TCRR does not add any resynchronization latency; the current value is always available.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

The drawback of this automatic update mechanism is that it assumes a given relationship between the timer interface frequency and the timer clock frequency.

Functional frequency range: freq(timer clock) freq(L4 interface clock)/4

16.2.6.1.2 Write Nonposting Synchronization Mode

This mode is used if the GPTi.[TSICR\[2\]](#) POSTED bit is set to 0.

This mode uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that both the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the L4 interface frequency and the timer clock frequency.

16.2.6.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers (GPTi.[TCRR](#), GPTi.[TCAR1](#), and GPTi.[TCAR2](#)) captures the current timer counter value. This must be followed by reading the 16MSBs.

IVA2.2 subsystem 16-bit accesses can be interleaved with MPU subsystem 32-bit accesses.

NOTE: LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

16.3 General-Purpose Timers Register Manual

16.3.1 GP Timer Register Map

16.3.1.1 Instance Summary

[Table 16-12](#) lists the base address and block size for the GP timer module instances. All timers are memory mapped to the L4 peripheral bus memory space.

Table 16-12. GP Timer Instance Summary

Module Name	Base Address	Size
GPTIMER1	0x4831 8000	4K bytes
GPTIMER2	0x4903 2000	4K bytes
GPTIMER3	0x4903 4000	4K bytes
GPTIMER4	0x4903 6000	4K bytes
GPTIMER5	0x4903 8000	4K bytes
GPTIMER6	0x4903 A000	4K bytes
GPTIMER7	0x4903 C000	4K bytes
GPTIMER8	0x4903 E000	4K bytes
GPTIMER9	0x4904 0000	4K bytes
GPTIMER10	0x4808 6000	4K bytes
GPTIMER11	0x4808 8000	4K bytes

16.3.2 GP Timer Register Mapping Summary

CAUTION

The GP timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

[Table 16-13](#) through [Table 16-15](#) provide the register summary and associated offset addresses for the 11 GP timer internal registers. (Example: The physical address for the [TCLR](#) register of GPTIMER8 is 0x4903 E024.)

Table 16-13. GPTIMER1 to GPTIMER4 Register Summary

Reserved																									CLOCKACTIVITY	Reserved	EMUFREE	IDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	DESCRIPTION	Type	Reset
31:10	Reserved	Write 0s for future compatibility. Reads return 0.	R	0x00000000
9:8	CLOCKACTIVITY	Clock activity during wakeup mode period: 0x0: L4 interface and Functional clocks can be switched off. 0x1: L4 interface clock is maintained during wake-up period; Functional clock can be switched off. 0x2: L4 interface clock can be switched off; Functional clock is maintained during wake-up period. 0x3: L4 interface and Functional clocks are maintained during wake-up period.	RW	0x0
7:6	Reserved	Write 0s for future compatibility. Reads return 0.	R	0x0
5	EMUFREE	Emulation mode 0x0: Timer counter frozen in emulation 0x1: Timer counter free-running in emulation	RW	0
4:3	IDLEMODE	Power management, req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally. 0x1: No-idle. An idle request is never acknowledged. 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module.	RW	0x0

Bits	Field Name	DESCRIPTION	Type	Reset
		0x3: Reserved. Do not use.		
2	ENAWAKEUP	Wake-up feature global control 0x0: No wake-up line assertion in idle mode 0x1: Wake-up line assertion enabled in smart-idle mode	RW	0
1	SOFTRESET	Software reset. This bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0
0	AUTOIDLE	Internal L4 interface clock gating strategy 0x0: L4 interface clock is free-running. 0x1: Automatic L4 interface clock gating strategy is applied, based on the L4 interface activity.		0

General-Purpose Timers Register Manual

www.ti.com

Bits	Field Name	Description	Type	Reset
31:15	Reserved	Reads return 0.	R	0x00000
14	GPO_CFG	PWM output/event detection input pin direction control: 0x0: Configures the pin as an output (needed when PWM mode is required) 0x1: Configures the pin as an input (needed when capture mode is required)	RW	0
13	CAPT_MODE	Capture mode select bit (first/second) 0x0: Capture the first enabled capture event in TCAR1 . 0x1: Capture the second enabled capture event in TCAR2 .	RW	0
12	PT	Pulse or toggle select bit 0x0: Pulse modulation 0x1: Toggle modulation	RW	0
11:10	TRG	Trigger output mode 0x0: No trigger 0x1: Overflow trigger 0x2: Overflow and match trigger 0x3: Reserved	RW	0x0
9:8	TCM	Transition capture mode 0x0: No capture 0x1: Capture on rising edges of EVENT_CAPTURE pin. 0x2: Capture on falling edges of EVENT_CAPTURE pin. 0x3: Capture on both edges of EVENT_CAPTURE pin.	RW	0x0
7	SCPWM	Pulse-width-modulation output pin default setting when counter is stopped or trigger output mode is set to no trigger. 0x0: Default value of PWM_out output: 0 0x1: Default value of PWM_out output: 1	RW	0
6	CE	Compare enable 0x0: Compare disabled 0x1: Compare enabled	RW	0
5	PRE	Prescaler enable 0x0: Prescaler disabled 0x1: Prescaler enabled	RW	0
4:2	PTV	Trigger output mode 0x0: The timer counter is prescaled with the value: $2^{(PTV+1)}$. Example: PTV = 3, counter increases value (if started) after 16 functional clock periods.	RW	0x0
1	AR	Autoreload mode 0x0: One-shot mode overflow 0x1: Autoreload mode overflow	RW	0
0	ST	Start/stop timer control 0x0: Stop the timer 0x1: Start the timer	RW	0

16.4 Watchdog Timers

16.4.1 WDTs Overview

The device includes two instances of the 32-bit WDT: WDT2 and WDT3. [Figure 16-14](#) shows how each timer is connected in the device.

NOTE: WDT*i* (where *i* is the watchdog timer instance: *i* = 2 or 3) stands for the following:

- WDT2: Watchdog timer 2, also called MPU watchdog timer
- WDT3: Watchdog timer 3, also called IVA2 watchdog timer

Each WDT is an upward counter capable of generating both a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The MPU WDT serves resets to the PRCM module (its interrupt outputs are unused), and the IVA2 WDT serves watchdog interrupts to the MPU (its reset outputs are unused).

The WDTs can be accessed, loaded, and cleared by registers through the L4 interface. The MPU and IVA2 WDTs have the 32-kHz clock for their timer clock input.

The MPU WDT directly generates a warm reset condition on overflow. The IVA2 WDT generates an MPU interrupt condition on overflow, which can be used by the application software via the PRCM to indirectly trigger a reset condition (that is, to the IVA2 subsystem).

The MPU WDT connects to a single target agent port on the L4 interconnect.

Table 16-56. WD Timers Default State for GP and EMU devices

Timer	Device				
	EMU		GP		
MPU_WDTIMER2	Enabled	Running	Enabled	Running	
IVA2_WDTIMER3	Enabled	NOT Running	Enabled	NOT Running	

Figure 16-14. WDTs Block Diagram

timers-014

16.4.1.1 WDT Features

The following are the main features of the WDT controllers:

- L4 slave interface support:

- 32-bit data bus width
- 32-/16-bit access supported
- 8-bit access not supported
- 11-bit address bus width
- Burst mode not supported
- Only posted write/read internal resynchronization mode supported
- Free-running 32-bit upward counter
- Programmable divider clock source (2^n with $n=[0:7]$)
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer
- WDTs are reset either on power-on or after a warm reset.
- Reset or interrupt actions when a timer overflow condition occurs
- WDT generates either a reset or an interrupt in its hardware integration (WDT2, or WDT3).

16.4.2 WDT Integration

Figure 16-15 shows the integration of the WDT in the device.

Figure 16-15. WDT Integration

16.4.2.1 Clocking, Reset, and Power-Management Scheme

16.4.2.1.1 Clock Management

There are two clock domains in the WDTs:

- Functional clock domain: WDT_i_FCLK is the WDT functional clock. It is used to clock the WDT internal logic.
- Interface clock domain: WDT_i_ICLK is the WDT interface clock. It is used to synchronize the WDT L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WDT_i_ICLK.

Table 16-57 lists the source clocks for each WDT in the device. For more information on clock control and domains, see [Chapter 3, Power, Reset, and Clock Management](#).

Table 16-57. Clock, Power, and Reset Domains for WDTs

Timer	Interface Clock	Functional Clock	Power Domain
MPU WDT	WKUP_L4_ICLK	WKUP_32K_FCLK	WKUP
IVA2 WDT	PER_L4_ICLK	PER_32K_ALWON_FCLK	PER

From a global system power-management perspective, when one or both of the WDT clocks is no longer required, the WDTs can be deactivated at the PRCM level in the corresponding registers. [Table 16-58](#) lists the WDT PRCM clock control bits.

Table 16-58. WDT PRCM Clock Control Bits

Name	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
WDT2_FCLK	WKUP_32K_FCLK	PRCM.CM_FCLKEN_WKUP[5] EN_WDT2 bit	N/A
WDT3_FCLK	PER_32K_ALWON_FCLK	PRCM.CM_FCLKEN_PER[12] EN_WDT3 bit	N/A
WDT2_ICLK	WKUP_L4_ICLK	PRCM.CM_ICLKEN_WKUP[5] EN_WDT2 bit	PRCM.CM_AUTOIDLE_WKUP[5] AUTO_WDT2 bit
WDT3_ICLK	PER_L4_ICLK	PRCM.CM_ICLKEN_PER[12] EN_WDT3 bit	PRCM.CM_AUTOIDLE_PER[12] AUTO_WDT3 bit

NOTE:

- The PRCM function clock outputs are gated at the PRCM level, assuming the modules that share it have been disabled in the corresponding register. Disabling the WDTs is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see [Chapter 3, Power, Reset, and Clock Management](#).
- The PRCM interface clock outputs are gated at the PRCM level, assuming the modules that share it have been disabled in the corresponding register. Disabling the WDTs is a necessary but not sufficient condition. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see [Chapter 3, Power, Reset, and Clock Management](#).
- The PRCM AUTOIDLE bits are used to link/unlink the WDTs from the clock domain transitions related to the GPTI_ICLK clocks.
- For further details about source clocks gating and domain transitions, see [Chapter 3, Power, Reset, and Clock Management](#).

At the PRCM level, when the conditions to shut off the PRCM functional or interface output clocks are met (see [Chapter 3, Power, Reset, and Clock Management](#), for details), the PRCM automatically launches a hardware handshake protocol to ensure the WDT is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the WDT.

Although this handshake is a hardware function and out of software control, the way the WDT acknowledges the PRCM IDLE request is configurable through the WDTi.WD_SYSCONFIG[4:3] IDLEMODE bit. [Table 16-59](#) lists the IDLEMODE settings and the related acknowledgement modes.

Table 16-59. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The WDT acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent loss of data when the clock is switched off.
01	No-idle	The WDT never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures the clocks remain active; it is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.

Table 16-59. IDLEMODE Settings (continued)

IDLEMODE Value	Selected Mode	Description
10	Smart-idle	The WDT acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQs requests are treated. This is the best approach for efficient system power management.
11	Reserved	

When configured in smart-idle mode, the WDT also offers an additional granularity on WDTi_FCLK and WDTi_ICLK gating. The WDTi.WD_SYSCONFIG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (WDTi_FCLK, WDTi_ICLK, neither of them, or both of them).

The CLOCKACTIVITY setting is used internally to the WDT to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request will be tested. For example, if WDTi_FCLK is not to be shut down on a PRCM IDLE request, the WDT considers only WDTi_ICLK and the associated pending activities before acknowledging the request.

Some WDT features are associated with WDTi_ICLK, and others are associated with WDTi_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that will remain active are always enabled, even if the WDT acknowledges an IDLE request.

Table 16-60 lists the CLOCKACTIVITY settings.

Table 16-60. CLOCKACTIVITY Settings

CLOCKACTIVITY Value	WDTi_ICLK Effects	WDTi_FCLK Effects	Description
00	OFF	OFF	Both WDTi_ICLK and WDTi_FCLK are considered for generating the acknowledge. This setting also means both WDTi_FCLK and WDTi_ICLK are likely to be shut down on a PRCM IDLE request.
01	OFF	ON	WDTi_FCLK is not shut down on a PRCM IDLE request; only WDTi_ICLK is concerned.
10	ON	OFF	WDTi_ICLK is not shut down on a PRCM IDLE request; only WDTi_FCLK is concerned.
11	ON	ON	None of the clocks are shut down. Therefore, the WDT can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks.

CAUTION

The PRCM module does *not* have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the WDT CLOCKACTIVITY and the PRCM functional clock and interface clock control bits. If the WDT is disabled in both the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the WDT clocks. This can lead to unpredictable behavior.

16.4.2.1.2 Reset and Power Management

The MPU WDT (WDT2) belong to the WKUP power domain. As part of that domain, this WDT is sensitive to a WKUP_RST signal issued by the PRCM module. For further details about the WKUP power domain implementation and WKUP_RST signal, see [Chapter 3, Power, Reset, and Clock Management](#).

The IVA WDT (WDT3) belongs to the PER power domain. As part of that domain, WDT3 is sensitive to the PER_RST signal issued by the PRCM module. For further details about the PER power domain implementation and PER_RST signal, see [Chapter 3, Power, Reset, and Clock Management](#).

NOTE: WDT2 is reset on power-on or after a warm reset, and then it starts counting.

WDT3 is reset either on power-on or after a warm reset, and then it doesn't start counting.

16.4.2.2 Interrupts

Table 16-61 shows interrupt mapping from the three WDTs to the MPU.

Table 16-61. WDT Interrupt Names and Processor IRQ Mapping

Timer	Interrupt Name	Mapping	Comments
MPU WDT	WDT2_IRQ	Not connected	
IVA2 WDT	WDT3_IRQ	M_IRQ_36	IVA2 WDT overflow

16.4.3 WDTs Functional Description

16.4.3.1 General WDT Operation

The WDTs are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. The use of these signals depends on whether they are connected or not. For this information, see Figure 16-14. The interrupt generation mechanism is controlled through the WDTi.WIER and WDTi.WISR registers.

The prescaler ratio can be set between 1 and 128 by accessing the WDTi.WCLR[4:2] PTV and WDTi.WCLR[5] PRE fields of the watchdog control register (WDTi.WCLR).

The current timer value can be accessed on-the-fly by reading the WDT counter register (WDTi.WCRR), modified by accessing the WDT load register (WDTi.WLDR) (no on-the-fly update), or reloaded by following a specific reload sequence on the WDT trigger register (WDTi.WTGR). A start/stop sequence applied to the WDT start/stop register (WDTi.WSPR) can start and stop the WDT.

Figure 16-16. 32-Bit WDT Functional Block Diagram

timers-016

16.4.3.2 Reset Context

After reset, the WDTs are enabled. Table 16-62 lists the default reset values of the three WDT load registers (WDTi.WLDR) and prescaler ratios (WDTi.WCLR[4:2] PTV field). To get these values, software must read the corresponding WDTi.WCLR[4:2] PTV fields and the 32-bit register to retrieve the static configuration of the module.

Table 16-62. Count and Prescaler Default Reset Values

Timer	WLDR Reset Value	PTV Reset Value
DEVICE WDT (WDT2)	0xFFFFB 0000	0
IVA2 WDT (WDT3)	0xFFFFB 0000	0

16.4.3.3 Overflow/Reset Generation

When the WDT counter register (WDTi.WCRR) overflows, an active-low reset pulse is generated to the PRCM module. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the watchdog load register (WDTi.WLDR) and the prescaler is reset (the prescaler ratio remains unchanged). Then, after the reset pulse output has been generated, the timer counter begins incrementing again.

Figure 16-17 shows a general functional view of the WDT.

Figure 16-17. WDT General Functional View

timers-017

16.4.3.4 Prescaler Value/Timer Reset Frequency

Each WDT is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the WDTi.WCLR[5] PRE bit and the WDTi.WCLR[4:2] PTV field)
- Value loaded into the timer load register (WDTi.WLDR)

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the WDTi.WCLR[4:2] PTV field) and is enabled with the WDTi.WCLR[5] PRE bit.

Table 16-63 lists the prescaler clock ratio values.

Table 16-63. Prescaler Clock Ratios

PRE Bit (in WDTi.WCLR Register)	PTV Bits (in WDTi.WCLR Register)	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

The watchdog timer overflow rate is expressed by: $OVF_Rate = (0xFFFF FFFF - WDTn.WLDR + 1) * (wd-functional clock period) * PS$

With wd-functional clock period = $1 / (\text{wd-functional clock frequency})$ and $PS = 2^{(\text{PTV})}$.

CAUTION

Internal resynchronization causes any software write to GPTn.WSPR to have some latency before WSPR is updated with the programmed value:

$1.5 * \text{functional clock cycles} \leq \text{write_WSPR_latency} \leq 2.5 * \text{functional clock cycles}$

Remember to take this latency into account whenever the watchdog must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 0x1 (clock divided by 2) and WDTi.WCLR[5] PRE bit = 1 (clock divider enabled), the reset period is as listed in [Table 16-64](#).

Table 16-64. Reset Period Examples

WDTi.WLDR Value	Reset Period
0x0000 0000	74 h 56 min
0xFFFF 0000	4 s
0xFFFF FFF0	1 ms
0xFFFF FFFF	62.5 us

CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a WDT is enabled, the software must periodically trigger a reload before the counter overflows. Hence, the WDTi.WLDR[31:0] value must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, WDTi.WLDR[31:0] = 0xFFFF FFFF is a special case, although such a WDTi.WLDR value is meaningless. When WDTi.WLDR is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the WDT is stopped.

[Table 16-65](#) lists the default reset periods for the WDTs.

Table 16-65. Default WDT Time Periods

WDTs	Clock Source	Default Reset Period
DEVICE/IVA2 WDTs	32 kHz	10 s

16.4.3.5 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the WDT trigger register (WDTi.WTGR) using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the WDT trigger register (WDTi.WTGR) differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without a reset pulse generation.

The timer counter is loaded with the WDT load register value (the WDTi.WLDR[31:0] TIMER_LOAD field), and the prescaler is reset.

16.4.3.6 Start/Stop Sequence for WDTs (Using WDTi.WSPR Register)

To start/stop a WDT, access must be made through the start/stop register (WDTi.WSPR) using a specific sequence.

To disable the timer, follow this sequence:

1. Write 0xXXXX AAAA in WDTi.WSPR.
2. Write 0xXXXX 5555 in WDTi.WSPR.

To enable the timer, follow this sequence:

1. Write 0xXXXX BBBB in WDTi.WSPR.
2. Write 0xXXXX 4444 in WDTi.WSPR.

All other write sequences on WDTi.WSPR have no effect on the start/stop feature of the module.

16.4.3.7 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (WDTi.WCRR), prescaler ratio (the WDTi.WCLR[4:2] PTV field), or load value (the WDTi.WLDR[31:0] TIMER_LOAD field), the WDT must be disabled by using the start/stop sequence (the WDTi.WSPR register).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (WDTi.WTGR).

16.4.3.8 Watchdog Counter Register Access Restriction (WDTi.WCRR Register)

Because the WDTi.WCRR register is directly related to the timer counter value and is updated on the timer clock (WDTi_FCLK), a 32-bit shadow register is implemented to read a coherent value of the WDTi.WCRR register. The shadow register is updated by a 16-bit LSB read command.

NOTE: Although the L4 clock (WDTi_ICLK) is completely asynchronous with the timer clock (WDTi_FCLK), some synchronization is done to ensure that the WDTi.WCRR value is not read while it is being incremented.

When 32-bit read access is performed, the shadow register is not updated. Read access is made directly from the accessed register.

To ensure that a coherent value is read inside WDTi.WCRR, the first read access is to the lower 16 bits (offset = 0x08), followed by read access to the upper 16 bits (offset = 0x0A).

16.4.3.9 WDT Interrupt Generation

The WDT issues an overflow interrupt if this interrupt is enabled in the WDT interrupt enable register (WDTi.WIER[0] OVF_IT_ENA = 1). When the overflow occurs, the interrupt status bit (the WDTi.WISR[0] OVF_IT_FLAG bit) is set to 1. The output interrupt line (WDTi_IRQ) is asserted (active low) when both status (OVF_IT_FLAG) and enable (OVF_IT_ENA) flags are set to 1; the order is not relevant. Writing 1 in the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status after). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the WDTi.WISR register. Reading the WDTi.WISR register and writing the value back allows a fast acknowledge interrupt process.

NOTE: Writing 0 in the WDTi.WISR[0] OVF_IT_FLAG bit has no effect on it.

Because the interrupt event is generated on the functional clock domain (WDTi_FCLK), during the interrupt status register (WDTi.WISR) update, the two clock domains are resynchronized.

16.4.3.10 WDT Under Emulation

During emulation mode, the WDT can/cannot continue running, according on the value of the WDTi.WD_SYSCONFIG[5] EMUFREE bit of the system configuration register (WDTi.WD_SYSCONFIG).

- When EMUFREE is 1, WDT execution is not stopped and a reset pulse is still generated when overflow is reached.
- When EMUFREE is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting from emulation mode.

16.4.3.11 Accessing Watchdog Timer Registers

Posted mode applies only to functional registers that require synchronization on/from the timer functional clock domain (WDTi_FCLK). For a write/read operation, the following registers are affected:

- WDT_WCLR
- WDT_WCRR
- WDT_WLDR
- WDT_WTGR
- WDT_WDLY
- WDT_WSPR

NOTE: To ensure completion of successive writes in a WDT2 / WDT3 functional clock domain register, user software must poll the appropriate WDT_WWPS status bit.

NOTE: To ensure coherent reading when a read transaction immediately follows a write access to a WDT2/WDT3 functional clock domain register, user software must check the appropriate WDT_WWPS status bit.

The synchronous registers in the timer interface clock domain are not affected by the posted mode mechanism; the write/read operation is effective and acknowledged (command accepted) after one WDT_ICLK cycle from the command assertion. The synchronous registers in the timer interface clock domain are:

- WDT_WIDR
- WDT_WDSC
- WDT_WDST
- WDT_WIRQSTATRAW
- WDT_WIRQSTAT
- WDT_WIRQENSET
- WDT_WIRQENCLR
- WDT_WIRQWAKEEN
- WDT_WWPS

NOTE: Accesses to the synchronous registers in the WDT2 and WDT3 functional clock domain are posted.

16.5 Watchdog Timer Register Manual

All registers are 32 bits wide and are accessible through the L4 interface with 16-bit or 32-bit access (read/write).

16.5.1 Instance Summary

Table 16-66 lists the base address and address space for the WDT module instances. All timers are memory mapped to the L4 peripheral bus memory space.

Table 16-66. WDT Instance Summary

Module Name	Base Address	Size
WDTIMER2	0x4831 4000	4KB
WDTIMER3	0x4903 0000	4KB

16.5.2 WDT Register Mapping Summary

CAUTION

The WDT registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

Table 16-67 lists the WDT2 registers and Table 16-68 lists the WDT3 registers.

16.6 32-kHz Synchronized Timer

16.6.1 32-kHz Sync Timer Functional Description

The 32-kHz sync timer is a 32-bit counter, clocked by the falling edge of the 32-kHz system clock. It is reset while the external asynchronous power-up reset (sys_nrespwron) primary I/O is active (main device reset). When sys_nrespwron is released (on the rising edge of sys_nrespwron), after three 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock. After reaching its highest value, the counter wraps back to 0 and starts counting again. [Figure 16-18](#) shows the block diagram of the 32-kHz sync timer.

NOTE: sys_nrespwron is an active low I/O.

Figure 16-18. 32-kHz Sync Timer Block Diagram

16.6.1.1 Reading the 32-kHz Sync Timer

The sync counter register is 32 bits wide and for correct count capture must be accessed as 16-bit LSB access first and two 16-bit MSB access last. Internal synchronization logic allows reading of the counter value while the counter is running. The time latency to read the counter is one L4 interconnect clock period.

16.6.1.2 32-kHz Sync Timer Features

The following are the main features of the 32-kHz sync timer controller:

- L4 slave interface support:
 - 32-bit data bus width
 - 32-/16-bit access supported
 - 8-bit access not supported
 - 16-bit address bus width
 - Burst mode not supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0, highest value reached (0xFFFF FFFF)
- On-the-fly read (while counting)

16.6.2 32-kHz Sync Timer Environment

The sync timer is accessible only through the L4 interface.

16.6.3 32-kHz Sync Timer Integration

16.6.3.1 Clocking, Reset, and Power-Management Scheme

Table 16-91 lists the power and reset domain and the source clock for the 32-kHz sync timer in the device. For more information on power, reset, and clock control and domains, see [Chapter 3, Power, Reset, and Clock Management](#).

Table 16-91. Clock, Power, and Reset Domains for 32-kHz Sync Timer

Timer	Source Clock	Interface Clock	Clock and Power Domain	Reset Domain
32-kHz sync timer	sys_32k	32KSYNC_ICLK	WKUP	SYNCT_RST ⁽¹⁾

16.6.3.2 Interrupts

The 32-kHz sync timer has no interrupt outputs.

16.6.3.3 Sync Timer 32k and MSuspend Signal

By default, the Sync Timer 32k is not stopped when the MPU or DSP is in *halt*. To activate its sensitivity to the MSuspend signal, the CONTROL.CONTROL_MSUSPEND_2[29:27] SyncTMMctrl bit has been added to the system control module.

16.7 32-kHz Sync Timer Register Manual

16.7.1 32-kHz Sync Timer Instance Summary

[Table 16-92](#) lists the base address and block size for the 32-kHz sync timer. It is memory mapped to the L4 peripheral bus memory space.

Multimaster High-Speed I²C Controller

This chapter describes the four multimaster high-speed (HS) inter-integrated circuit (I²C) TM controllers integrated in the device. For reading ease, the multimaster high-speed controller 1, 2, 3, and 4 will be referred and factorized as HS I²C*i*.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

17.5 HS I ² C Basic Programming Model	2820
17.6 HS I ² C Register Manual	2840

17.1 HS I²C Overview

The device contains four multimaster high-speed (HS) inter-integrated circuit (I²C) TM controllers (I²C_i, where $i = 1, 2, 3$, or 4), each of which provides an interface between a local host (LH), such as the microprocessor unit (MPU) subsystem, and any I²C-bus-compatible device that connects through the I²C serial bus. External components attached to the I²C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I²C interface.

Each HS I²C controller can be configured to act like a slave or master I²C-compatible device. Moreover, each HS I²C controller can be configured in serial camera control bus (SCCB) mode (the SCCB is a serial bus developed by Omnivision Technologies, Inc.) to act as a master on a 2-wire SCCB bus. Only HS I²C2 and I²C3 can be configured in SCCB mode to act as a master device on a 3-wire SCCB bus.

The fourth HS I²C4 controller (I²C4) is in the power, reset, and clock management (PRCM) module to perform dynamic voltage control and power sequencing. For mode details on I²C4 see [Chapter 3, Power, Reset, and Clock Management](#). Moreover,

[Figure 17-1](#) shows the HS I²C controller in the device.

Figure 17-1. HS I²C Controllers Overview Block Diagram

(1) $i = 1, 2, 3$ and 4. Where i²C_i sccb is available only when $i=2$ and 3.

The three HS I²C controllers have the following features:

- Compliance with Philips I²C specification version 2.1
- Support for standard mode (up to 100Kbps) and fast mode (up to 400Kbps)
- Support for HS mode for transfer up to 3.4Mbps
- Support for 3-wire/2-wire SCCB master mode for I²C2 and I²C3 modules, 2-wire SCCB master mode for I²C1 module, up to 100K bits/s
- 7-bit and 10-bit device addressing modes
- General call

- Start/restart/stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in FIFOs (8, 16, 32, 64 bytes size) for buffered read or write
- Module enable/disable capability
- Programmable clock generation
- 8-bit-wide data access
- Low-power consumption design
- Two direct memory access (DMA) channels
- Wide interrupt capability
- Auto Idle mechanism
- Idle Request / Idle Acknowledge handshake mechanism

The master transmitter HS I²C4 controller has the following features:

- Support of HS and fast modes
- 7-bit addressing mode only
- Master transmitter mode only
- Start/restart/stop

NOTE: Before using HS I²C mode, determine that the target device supports this mode.

17.2 HS I²C Environment

17.2.1 HS I²C in I²C Mode

Figure 17-2 shows the HS I²C controllers and their related connections with I²C-compliant devices in I²C mode.

Figure 17-2. HS I²C Controllers and Typical Connections to I²C Devices

i2c-002

17.2.1.1 HS I²C Pins for Typical Connections in I²C Mode

Figure 17-3 shows the HS I²C controllers pins used for typical connections with I²C devices.

Figure 17-3. HS I²C Controller Interface Signals in I²C Mode

i2c-003

NOTE: In master mode, the clock signal (IP clk configured as output) is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

17.2.1.2 HS I²C Interface Typical Connections

Table 17-1 lists the pins associated with the I²C interface.

Table 17-1. HS I²C Input/Output

Signal	I/O ⁽¹⁾	Description	Reset Value
i2ci_scl	I/O(OD)	I ² C serial clock line ⁽²⁾ . Open-drain output buffer. Requires external pullup resistor (Rp).	Hi-Z for $i=1$; 1 for $i=2,3$
i2ci_sda	I/O(OD)	I ² C serial data line. Open-drain output buffer. Requires external Rp.	Hi-Z for $i=1$; 1 for $i=2,3$

⁽¹⁾ I = Input; O = Output; OD = Open Drain; Hi-Z = High Impedance

⁽²⁾ This signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

17.2.1.3 HS I²C Typical Connection Protocol and Data Format

17.2.1.3.1 HS I²C Serial Data Format

The HS I²C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line (i2ci_sda) is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the HS I²C. Figure 17-4 shows a typical HS I²C communication format.

Figure 17-4. HS I²C Serial Data Transfer

i2c-004

17.2.1.3.2 HS I²C Data Validity

The data on the serial data line must be stable during the high period of the clock i2ci_scl. The high and low states of the data line can change only when the clock signal on the serial clock line is low.

Figure 17-5 is an example of data validity requirements.

Figure 17-5. HS I²C Bit Data Validity Transfer on the I²C Bus

i2c-005

17.2.1.3.3 HS I²C Start and Stop Conditions

The HS I²C module generates start (S) and stop (P) conditions when it is configured as a master.

- An S condition is a high-to-low transition on the i2ci_sda line while i2ci_scl is high.
- A P condition is a low-to-high transition on the i2ci_sda line while i2ci_scl is high.

The bus is considered busy after the S condition (the I₂C_i.I₂C_STAT[12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I₂C_i.I₂C_STAT[12] BB bit is 0 to indicate that the bus is free).

Figure 17-6 shows the waveforms that occur during an S and a P condition.

Figure 17-6. HS I²C Start and Stop Condition Events

i2c-006

17.2.1.3.4 HS I²C Addressing

The HS I²C controller supports two data formats in fast/standard (F/S) and HS modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

17.2.1.3.4.1 HS I²C Data Transfer Format in F/S Mode

Figure 17-7 shows the I²C data transfer format in F/S mode.

Figure 17-7. HS I²C Data Transfer Formats in F/S Mode

(a) 7-bit addressing format

(b) 10-bit addressing format

(c) addressing format with repeated start condition

i2c-007

The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W_ bit.

The LSB R/W_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W_ is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W_ bit. If the R/W_ bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W_ bit is 1, the next byte contains data transmitted from the slave to the master.

17.2.1.3.4.2 HS I²C Data Transfer Format in HS Mode

Figure 17-8 shows the I²C data transfer format in HS mode.

Figure 17-8. HS I²C Data Transfers in HS Mode

Each HS I²C controller module can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the master code address (000001XXX, where XXX is the variable portion of the master code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the slave address and the data, as shown in Figure 17-8.

NOTE: For more information, see *I²C Bus Specification v2.1*, January 2000.

17.2.1.3.5 HS I²C Master Transmitter Mode

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on serial data line i₂ci_sda in synchronization with the self-generated clock pulses on serial clock line i₂ci_scl. When the intervention of the processor is required (the I₂C_i.I₂C_STAT[10] XUDF bit) after a byte is transmitted, the clock pulses are inhibited and the serial clock line is held low.

17.2.1.3.6 HS I²C Master Receiver Mode

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 17-7), if the R/W_ bit is high, the module enters master receiver mode after the slave address byte and bit R/W_ are transmitted. Serial data bits received on bus line i₂ci_sda are shifted in synchronization with the self-generated clock pulses on i₂ci_scl. When the intervention of the processor is required (the I₂C_i.I₂C_STAT[11] ROVR bit) after a byte is transmitted, the clock pulses are inhibited and the serial clock line is held low. At the end of a transfer, a P condition is generated.

17.2.1.3.7 HS I²C Slave Transmitter Mode

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 17-7), slave transmitter mode is entered if the slave address byte is the same as its own address, and when the R/W_ bit transmitted by the master transmitter is high. The slave transmitter shifts the serial data out on data line i₂ci_sda in synchronization with the clock pulses generated by the master device. It does not generate the clock, but it can hold clock line i₂ci_scl low when intervention of the LH is required (the I₂C_i.I₂C_STAT[10] XUDF bit).

17.2.1.3.8 HS I²C Slave Receiver Mode

In slave receiver mode, serial data bits received on bus line i₂ci_sda are shifted in synchronization with the clock pulses on i₂ci_scl generated by the master device. The slave receiver does not generate the clock, but it can hold the serial clock line low when intervention of the LH is required (the I₂C_i.I₂C_STAT[11] ROVR bit) after a byte is received.

17.2.1.3.9 HS I²C Bus Arbitration

If two or more master transmitters start a transmission on the same bus simultaneously, an arbitration procedure is invoked. This arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to slave receiver mode, sets the arbitration lost flag (the I2C*i*.I2C_STAT[0] AL bit), and generates the arbitration lost interrupt. Figure 17-9 shows arbitration between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 17-9. HS I²C Arbitration Between Master Transmitters

17.2.1.3.10 HS I²C Clock Generation and Synchronization

Under normal conditions, only one master device generates clock signal i2ci_scl. During arbitration, however, there are two or more master devices, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that the device that first generates a low period of the clock line overrules the other devices. At this high-low transition, the clock generators of the other devices are forced to start generating their own low periods. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, all clock generators must enter the WAIT state. In this way, a slave can slow down a fast master, and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (Clock Stretching).

NOTE: In case the SCL or SDA lines are stuck low, the Bus Clear operation is supported:

If the clock line (SCL) is stuck low, the preferred procedure is to reset the bus using the hardware reset signal if your I²C devices have hardware reset inputs. If the I²C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.

If the data line (SDA) is stuck low, the master should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.

Figure 17-10 shows clock synchronization.

Figure 17-10. HS I²C Synchronization of I²C Clock Generators

17.2.2 HS I²C in SCCB Mode

The SCCB is a 3-wire serial bus developed by Omnivision Technologies, Inc. The SCCB can also operate in a modified 2-wire serial mode. For details, see the SCCB specifications version 2.1 document at <http://www.ovt.com/>.

The HS I²C controllers support the 2-wire SCCB protocol in master mode. Only I²C2 and I²C3 support the 3-wire SCCB protocol in master mode.

Figure 17-11 shows the HS I²C controllers and their related connections with 3-wire or 2-wire SCCB-compliant devices.

Figure 17-11. HS I²C Controllers and Typical Connections to SCCB Devices

(a) Typical connection with 3-wire SCCB devices

(b) Typical connection with 2-wire SCCB devices

i2c-011

NOTE: Only one 2-wire SCCB slave device can be connected to the 2-wire SCCB bus.

17.2.2.1 HS I²C Controller Pins for Typical Connections in SCCB Mode

Figure 17-12 shows the HS I²C controller pins used for typical connections with 3-wire or 2-wire SCCB devices.

Figure 17-12. HS I²C Controller Interface Signals in SCCB Mode

17.2.2.2 HS I²C SCCB Interface Typical Connections

[Table 17-2](#) lists the pins associated with the SCCB interface.

Table 17-2. HS I²C Input/Output

Signal	I/O ⁽¹⁾	Description	Reset Value	I2Ci.I2C_CON[15] I2C_EN = 0
i2ci_scl	O	SCCB serial clock line ⁽²⁾ . Standard CMOS output buffer.	Hi-Z	High
i2ci_sda	I/O(OD)	SCCB serial data line. Standard CMOS 3-state output buffer. Requires external conflict-protection resistor for each slave device connected to the bus.	Hi-Z	Hi-Z
i2ci_sccbe ⁽³⁾	O	SCCB enable line. Standard CMOS output buffer.	High	High

⁽¹⁾ I = Input; O = Output; OD = Open Drain; Hi-Z = High Impedance

⁽²⁾ This output signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

⁽³⁾ This signal is used for the 3-wire SCCB protocol only.

NOTE: Because they share the same ball, the i2c2_sccbe and i2c3_sccbe signals are not available at the same time. For detailed information about pin configuration, see [Chapter 13, System Control Module](#).

The HS I2C1 module does not provide any i2c1_sccbe signal at the chip boundary of the device; thus, this module does not support the 3-wire SCCB protocol.

17.2.2.3 HS I²C SCCB Typical Connection Protocol and Data Format

17.2.2.3.1 HS I²C Serial Transmission Timing Diagram

Figure 17-13 is the timing diagram of the 3-wire SCCB data transmission.

Figure 17-13. HS I²C 3-Wire SCCB Transmission Timing Diagram

NOTE: When operating in 2-wire SCCB mode, the i2ci_sccbe signal is not used by the 2-wire SCCB-compliant slave device attached to the 2-wire SCCB bus.

17.2.2.3.2 HS I²C SCCB Transmission Data Formats

Figure 17-14 describes the data format of the three kinds of transmission.

Figure 17-14. HS I²C SCCB Transmission Data Formats

R/W: 0 = Write, 1 = Read

X: Don't care

NA: Ninth bit of a read phase. This bit must be set to 1 by the master device.

Master to slave Slave to master

i2c-014

The basic element of a data transmission is a phase. A phase contains 9 bits, which consist of an 8-bit sequential data transmission followed by a ninth bit. The ninth bit is a don't-care bit (X) or an NA bit, depending on whether the data transmission is a write or a read. The maximum number of phases that can be included in a transmission is three. The MSB is always asserted first for each phase.

A data transmission is one of three types:

- **3-phase write transmission:** The 3-phase write transmission cycle (see (a) of [Figure 17-14](#)) is a full write operation in which the master can write 1 byte of data to a specific slave(s). The 7-bit slave address in the ID value identifies the specific slave that the master intends to access. The subaddress identifies the register location of the specified slave. The write data contains 8-bit data that the master intends to write over the content of this specific address. The ninth bit of each of the three phases is a don't-care bit (X bit).
- **2-phase write transmission:** The 2-phase write transmission cycle is followed by a 2-phase read transmission cycle (see below). The purpose of issuing a 2-phase write transmission cycle (see (b) of [Figure 17-14](#)) is to identify the subaddress of some specific slave from which the master intends to read data for the following 2-phase read transmission cycle. The ninth bit of each phase is a don't-care bit (X bit).
- **2-phase read transmission:** Either a 3-phase or a 2-phase write transmission cycle must be asserted ahead of a 2-phase read transmission cycle. The 2-phase read transmission cycle (see (c) of [Figure 17-14](#)) has no ability to identify the subaddress. The 2-phase write transmission cycle contains read data of 8 bits and a ninth don't-care bit or NA bit. The master must drive the NA bit at logical 1.

In each transmission type, phase 1 (the 7-bit slave address of the ID value) is asserted by the master to identify the selected slave to which the data is read or written. Each slave has a unique 7-bit slave address. The 7-bit slave address of the ID value comprises 7 bits, from bit 7 to bit 1, that can identify up to 128 slaves. The eighth bit, bit 0, is the read/write selector bit that specifies the transmission direction of the current cycle. A logical 0 represents a write cycle and a logical 1 represents a read cycle. The ninth bit of phase 1 is a don't-care bit (X bit).

Phase 2 (subaddress/read data) is asserted by the master (subaddress) or the slave(s) (read data). A phase 2 transmission asserted by the master identifies the subaddress of the slave(s) the master intends to access. A phase 2 transmission asserted by the slave(s) indicates the read data that the master will receive. The slave(s) recognize the subaddress of this read data according to the previous 3-phase or 2-phase write transmission cycle. The ninth bit is defined as a don't-care bit (X bit) when the master asserts phase 2. The ninth bit is defined as an NA bit when the slave(s) asserts the phase 2 transmission. The master is responsible for a logical 1 during the period of the NA bit.

Phase 3 (write data) is asserted only by the master. This phase contains the data the master intends to write to the slave(s). Because the master asserts the transmission, the ninth bit of the phase 3 transmission is defined as a don't-care bit (X bit).

NOTE: A HS I²C controller configured in SCCB mode can perform two operations:

- Writing a single byte to an SCCB slave device by using the 3-phase write transmission cycle
 - Reading a single byte from an SCCB slave device by using the 2-phase write transmission cycle followed by the 2-phase read transmission cycle
-

17.2.3 HS I²C Communication With Power Chip(s)

The HS I²C controller I2C4 interfaces between the external power chip(s) for voltage control. This module is always configured as an I²C master transmitter; it does not support the SCCB protocol. For a definition of master transmitter mode, see [Section 17.2.1.3.5, HS I²C Master Transmitter Mode](#).

[Figure 17-15](#) shows a typical connection between master transmitter HS I²C controller I2C4 of the device and external power chip(s).

Figure 17-15. HS I²C Typical Connection Between Power Chip(s) and for I²C4

17.2.3.1 HS I²C Pins for Typical Connections for I²C4

Figure 17-16 shows the HS I²C controller I²C4 pins used for typical connections with power chips. Its configuration is in master transmitter only high speed.

Figure 17-16. HS I²C Interface Signals for I²C4

17.2.3.2 HS I²C Interface Typical Connections for I²C4

Table 17-3 lists the pins associated with the I²C interface of the HS I²C controller I²C4 of the device.

Table 17-3. HS I²C Input/Output Description for I2C4

Signal	I/O ⁽¹⁾	Description	Reset Value
i2c4_scl	I/O(OD)	I ² C serial clock line ⁽²⁾ . Open-drain output buffer. Requires external Rp.	Hi-Z
i2c4_sda	I/O(OD)	I ² C serial data line. Open-drain output buffer. Requires external Rp.	Hi-Z

⁽¹⁾ I = Input; O = Output; OD = Open Drain; Hi-Z = High Impedance

⁽²⁾ This signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

17.2.3.3 HS I²C Typical Connections Protocol and Data Format for I2C4

17.2.3.3.1 HS I²C Serial Data Format for I2C4

The serial data format is the same as described in [Section 17.2.1.3.1, HS I²C Serial Data Format](#).

17.2.3.3.2 HS I²C Data Validity for I2C4

The data validity is the same as described in [Section 17.2.1.3.2, HS I²C Data Validity](#).

17.2.3.3.3 HS I²C Start and Stop Conditions for I2C4

The S and P conditions are the same as described in [Section 17.2.1.3.3, HS I²C Start and Stop Conditions](#).

17.2.3.3.4 HS I²C Addressing for I2C4

The master transmitter HS I²C controller I2C4 supports only the 7-bit addressing mode. For each frame, the master writes the 8-bit value (DATA) in the register specified by the 8-bit register address (RA) of the slave addressed by the slave address (SA).

17.2.3.3.4.1 HS I²C Data Transfer Format in F/S Mode for I2C4

[Figure 17-17](#) shows the HS I²C data transfer format in F/S mode for I2C4.

17.3 HS I²C Integration

Figure 17-19 shows the integration of the four HS I²C controllers in the device.

Figure 17-19. HS I²C Controller Integration Diagram

i2c019

17.3.1 HS I²C Clocking, Reset, and Power-Management Scheme

17.3.1.1 HS I²C Clocks

17.3.1.1.1 HS I²C Module Clocks

Each HS I²C controller is clocked with an independent functional clock of 96 MHz (I²C_i_FCLK) and an interface clock (I²C_i_ICLK) for interfacing with the L4-Core interconnect. These clocks are provided by the PRCM module.

The SYS_CLK clock provided by the clock generator of the PRCM module is connected to the functional and interface clocks of the HS I²C controller I2C4. For detailed information about the module clocking, see [Chapter 3, Power, Reset, and Clock Management](#).

The interface clock can be enabled or disabled for each HS I²C controller by setting the following bits in the PRCM module:

- PRCM.CM_ICLKEN1_CORE[15] EN_I2C1 bit for I2C1
- PRCM.CM_ICLKEN1_CORE[16] EN_I2C2 bit for I2C2
- PRCM.CM_ICLKEN1_CORE[17] EN_I2C3 bit for I2C3

The functional clock can be enabled or disabled for each multimaster HS I²C controller by setting the following bits in the PRCM module:

- PRCM.CM_FCLKEN1_CORE[15] EN_I2C1 bit for I2C1
- PRCM.CM_FCLKEN1_CORE[16] EN_I2C2 bit for I2C2
- PRCM.CM_FCLKEN1_CORE[17] EN_I2C3 bit for I2C3

The functional clock is processed by a prescaler block to produce the internal sampling clock. This clock is generated by the I²C prescaler block. The prescaler block consists of the I²C_i.I²C_PSC[7:0] PSC bit field (where $i = 1, 2, 3$) that is used to divide down the functional clock to obtain an internal sampling clock with a frequency value of I²C_i_FCLK/(I²C_i.I²C_PSC[7:0] PSC bit field value + 1, where $i = 1, 2, 3$).

NOTE: The I²C₄.I²C_PSC[7:0] PSC bit field of I²C₄ is not accessible by software. For details about the bit rates available for I²C₄, see [Section 17.4.7, HS I²C Clocking](#).

17.3.1.2 HS I²C Power Management

17.3.1.2.1 HS I²C Module Power Saving

This section describes power-saving techniques for the HS I²C controllers. To conserve power, when no activity is detected on the L4-Core interconnect interface of the module, each of these modules supports an automatic idle mode that is enabled or disabled by setting the I²C_i.I²C_SYSC[0] AUTOIDLE bit.

When this bit is asserted (set to 1), if no activity is detected on the L4-Core interface, automatic idle mode is enabled and the interface clock I²C_i_ICLK is disabled internally to the module, thus reducing power consumption.

When new activity is detected on the L4-Core interconnect interface of the module, the clock restarts with no latency penalty. After reset, automatic idle mode is disabled; thus, this mode must be enabled by software for reduced power consumption.

17.3.1.2.2 HS I²C System Power Management

As part of the system-wide power-management scheme, each HS I²C controller supports a communication protocol with the PRCM module to request the module to enter a low-power mode. When a module acknowledges a low-power mode request from the PRCM module, the interface and/or the functional clocks are gated off at the PRCM clock generator. Because the clocks are disabled at the source, the low-power mode offers lower power consumption than the internal clock autogating method used by local power management.

The PRCM.CM_ICLKEN1_CORE[15] EN_I2C1, PRCM.CM_ICLKEN1_CORE[16] EN_I2C2, and PRCM.CM_ICLKEN1_CORE[17] EN_I2C3 bits in the PRCM module control the interface clocks of the HS I²C1, I²C2, and I²C3 modules, respectively.

The PRCM.CM_FCLKEN1_CORE[15] EN_I2C1, PRCM.CM_FCLKEN1_CORE[16] EN_I2C2, and PRCM.CM_FCLKEN1_CORE[17] EN_I2C3 bits in the PRCM module control the functional clocks of the HS I²C1, I²C2, and I²C3 modules, respectively.

For details about clock enabling and disabling in the PRCM module, see [Chapter 3, Power, Reset, and Clock Management](#).

Each HS I²C controller can be configured through the I²C_i.I²C_SYSC[4:3] IDLEMODE bit field as one of the following acknowledgment modes:

- Force-idle mode (I²C_i.I²C_SYSC[4:3] IDLEMODE bit field = b00): The module immediately enters idle mode when a low-power-mode request is received from the PRCM module. In this mode, software must ensure that there are no asserted output interrupts before requesting this mode to go to IDLE state.
- No-idle mode (I²C_i.I²C_SYSC[4:3] IDLEMODE bit field = b01): The module never enters idle mode.
- Smart-idle mode (I²C_i.I²C_SYSC[4:3] IDLEMODE bit field = b10): After receiving a low-power-mode request from the PRCM module, the module enters idle mode only after all asserted output interrupts are acknowledged and there is no pending internal event.

NOTE: The value I²C_i.I²C_SYSC[4:3] IDLEMODE = b11 must not be used.

Table 17-4 describes the HS I²C controller power-management modes.

Table 17-4. HS I²C Power Management Modes

Power-Management Mode Requested by the PRCM Module	I ² C _i .I ² C_SYSC[4:3] IDLEMODE Bit Field Value (where i = 1, 2, 3)
Force-idle	b00
No-idle	b01
Smart-idle	b10
Reserved (not used)	b11

The PRCM module gates the interface and/or the functional clocks after receiving the acknowledgment of the I²C_i (where *i* = 1, 2, 3). The I²C_i.I²C_SYSC[9:8] CLOCKACTIVITY bit field indicates the state of the interface and functional clocks of the module when in idle mode. Table 17-5 lists the value of the I²C_i.I²C_SYSC[9:8] CLOCKACTIVITY bit field and indicates the state of the interface and functional clocks at the PRCM clock generator output in idle mode.

Table 17-5. HS I²C State of the Interface and Functional Clocks When the Module is in Idle Mode

I ² C _i .I ² C_SYSC[9:8] CLOCKACTIVITY Bit Field Value (where i= 1, 2, 3)	Functional Clock	Interface Clock
b00	Off	Off
b01	Off	On
b10	On	Off
b11	On	On

NOTE: The PRCM.CM_AUTOIDLE1_CORE[15] AUTO_I2C1, PRCM.CM_AUTOIDLE1_CORE[16] AUTO_I2C2, and PRCM.CM_AUTOIDLE1[17] AUTO_I2C3 bits control, for each HS I²C controller, whether the L4-Core interconnect interface clock is enabled or disabled in synchronization with the CORE power domain state transition (see [Chapter 3, Power, Reset, and Clock Management](#)).

NOTE: The voltage controller, in which HS I²C controller I2C4 is implemented, has no idle request/acknowledge mechanism. The idle modes for the voltage controller are directly managed by the PRM module. For details, see [Chapter 3, Power, Reset, and Clock Management](#).

17.3.1.2.3 HS I²C Wake-Up Capability

Each HS I²C controller can wake up the system by generating a wake-up request through the I²C_i_WAKE signal connected to the PRCM module.

The wake-up request is composed of the merge of all wake-up events. Each wake-up event can be separately enabled or disabled by setting the corresponding bit in the I2Ci.I²C_WE register.

The global wake-up capability of the module can be enabled or disabled by setting the I2Ci.I²C_SYSC[2] ENAWAKEUP bit (1: enabled; 0: disabled).

Figure 17-20 shows the wake-up generation flow.

Figure 17-20. HS I²C Wake-up Generation Flow

i2c-020

Table 17-6 lists all wake-up events with the corresponding enable/disable bit in the I2Ci.I²C_WE register.

Table 17-6. HS I²C Wake-Up Events

Wake-Up Event Name	Supported Configuration Mode	Enable/Disable Bit ⁽¹⁾	Event Generated When:
AL event	I ² C mode only	I2Ci.I ² C_WE[0] AL_WE	I2Ci in the device loses the arbitration of the I ² C bus in master transmitter mode.
NACK event	I ² C mode only	I2Ci.I ² C_WE[1] NACK_WE	A nonacknowledgment has been generated on the I ² C bus, indicating a transmission error.
ARDY event	I ² C receive mode and SCCB read mode	I2Ci.I ² C_WE[2] ARDY_WE	The current transaction is finished and the module registers can be accessed.
DRDY event	I ² C and SCCB modes	I2Ci.I ² C_WE[3] DRDY_WE	The TX FIFO needs some data to be transferred or the RX FIFO must be read.

⁽¹⁾ To enable the corresponding wake-up event generation, set the bit to 1. To disable the corresponding wake-up event generation, set the bit to 0.

Table 17-6. HS I²C Wake-Up Events (continued)

Wake-Up Event Name	Supported Configuration Mode	Enable/Disable Bit ⁽¹⁾	Event Generated When:
GC event	I ² C mode only	I2Ci.I2C_WE[5] GC_WE	A general call is received on the I ² C bus.
STC event ⁽²⁾	I ² C mode only	I2Ci.I2C_WE[6] STC_WE	A start (S) condition is detected on the I ² C bus. ⁽³⁾
BF event	I ² C and SCCB modes	I2Ci.I2C_WE[8] BF_WE	The bus is free and the LH can initiate its own transfer.
AAS event	I ² C mode only	I2Ci.I2C_WE[9] AAS_WE	An external master I ² C device addresses the module of the device to inform the LH that it can check which of its own addresses was used by the external master I ² C device to access the module of the device.
ROVR event	I ² C receive mode only	I2Ci.I2C_WE[10] ROVR_WE	Overrunning and draining while receiving.
XUDF event	I ² C transmit mode only	I2Ci.I2C_WE[11] XUDF_WE	Transmitting and receiving an underflow event during the transmission.
RDR event	I ² C receive mode only	I2Ci.I2C_WE[13] RDR_WE	The module, configured as a receiver, has detected a stop (P) condition on the I ² C bus and the RX FIFO threshold (I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1) is not reached and the RX FIFO is not empty. This allows the module to inform the LH that it can check the amount of data to be transferred from the RX FIFO.
XDR event	I ² C master transmit mode only	I2Ci.I2C_WE[14] XDR_WE	The TXFIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH bit field value + 1) and the amount of data left to be transferred is less than this threshold. This allows the module to inform the LH that it can check the amount of data to be written to the TX FIFO.

⁽²⁾ Wake-up event asynchronously detected.

⁽³⁾ This event must not be enabled if the functional clock cannot be disabled.

NOTE: With the exception of the STC event, the functional clock must be active for wake-up event detection to occur. The HS I2C4 has no wake-up capability.

17.3.1.3 HS I²C Resets

17.3.1.3.1 HS I²C Hardware Reset

The three HS I²C controllers receive their reset signal CORE_RST (the reset signal of the CORE power domain) from the PRCM module.

The HS I2C4 gets its reset signal PRM_RSTPWRON from the reset manager in the PRCM module.

17.3.1.3.2 HS I²C Software Reset

Each HS I²C controller supports the software reset by accessing the I2Ci.I2C_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2Ci.I2C_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2Ci.I2C_CON[15] I2C_EN bit to 0).
2. Set the I2Ci.I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2Ci.I2C_CON[15] I2C_EN bit to 1.
4. Check the I2Ci.I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

NOTE: The I²C*i*.I²C_CON[15] I²C_EN bit can hold the functional clock domain of the HS I²C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I²C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I²C*i*.I²C_CON[15] I²C_EN bit must be set to 1 to enable the functional part of the I²C controller.

The I²C*i*.I²C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I²C*i*.I²C_CON[15] I²C_EN bit to 1.

17.3.1.4 HS I²C Power Domain

The three HS I²C controllers are connected to the CORE power domain, whereas the HS I²C4 controller belongs to the WKUP power domain.

17.3.2 HS I²C Hardware Requests

17.3.2.1 HS I²C DMA Requests

Each HS I²C controller can generate two DMA requests to the system DMA (sDMA) controller. [Table 17-7](#) lists the DMA requests with mapping on the sDMA controller.

Table 17-7. HS I²C DMA Requests

Name	Source	Destination (sDMA controller)	Description
I ² C1_DMA_TX	I ² C1	S_DMA_26	I ² C1 DMA write request to inform the sDMA to write new data in the I ² C1.I ² C_DATA[7:0] register
I ² C1_DMA_RX	I ² C1	S_DMA_27	I ² C1 DMA read request to inform the sDMA to read the data in the I ² C1.I ² C_DATA[7:0] register
I ² C2_DMA_TX	I ² C2	S_DMA_28	I ² C2 DMA write request to inform the sDMA to write new data in the I ² C2.I ² C_DATA[7:0] register
I ² C2_DMA_RX	I ² C2	S_DMA_29	I ² C2 DMA read request to inform the sDMA to read the data in the I ² C2.I ² C_DATA[7:0] register
I ² C3_DMA_TX	I ² C3	S_DMA_24	I ² C3 DMA write request to inform the sDMA to write new data in the I ² C3.I ² C_DATA[7:0] register
I ² C3_DMA_RX	I ² C3	S_DMA_25	I ² C3 DMA read request to inform the sDMA to read the data in the I ² C3.I ² C_DATA[7:0] register

NOTE: The HS I²C4 does not generate any DMA request.

17.3.2.2 HS I²C Interrupt Requests

Each HS I²C controller can generate an interrupt I²C*i*_IRQ to the MPU subsystem. [Table 17-8](#) lists the interrupt requests with the mapping on the MPU interrupt controller (INTC).

Table 17-8. HS I²C Interrupt Requests

Name	Source	Destination (MPU INTC)
I ² C1_IRQ	I ² C1	M_IRQ_56
I ² C2_IRQ	I ² C2	M_IRQ_57
I ² C3_IRQ	I ² C3	M_IRQ_61

An event can generate an interrupt request when the corresponding mask bit in the I²C*i*.I²C_IE register is set to 1. [Table 17-9](#) summarizes the events causing the generation of an interrupt request.

Table 17-9. HS I²C Interrupt Events

Event Name	Supported Configuration Mode	Status Bit	Mask Bit	This Event Happens When:
AL event	I ² C mode only	I2C <i>i</i> .I ² C_STAT[0] AL	I2C <i>i</i> .I ² C_IE[0] AL_IE	Two or more I ² C master devices initiate a transfer and the I ² C module I ² C <i>i</i> in the device loses arbitration of the I ² C bus.
NACK event	I ² C mode only	I2C <i>i</i> .I ² C_STAT[1] NACK	I2C <i>i</i> .I ² C_IE[1] NACK_IE	A nonacknowledgment has been received. In master mode, the transfer is automatically ended by generating a stop condition on the bus. The I2C <i>i</i> .I ² C_CON[1] STP, I2C <i>i</i> .I ² C_CON[10] MST, and I2C <i>i</i> .I ² C_CON[9] TRX bits are automatically cleared to 0 (slave receiver mode). TX and RX FIFOs must be cleared (the I2C <i>i</i> .I ² C_BUF[6] TXFIFO_CLR and I2C <i>i</i> .I ² C_BUF[14] RXFIFO_CLR bits are set to 1).
ARDY event	I ² C and SCCB modes	I2C <i>i</i> .I ² C_STAT[2] ARDY	I2C <i>i</i> .I ² C_IE[2] ARDY_IE	One of the following cases occurs: <ul style="list-style-type: none"> • In I²C master receiver mode, the I2C<i>i</i>.I²C_CON[1] STP bit is set to 1, the I2C<i>i</i>.I²C_CNT[15:0] DCOUNT bit field value is 0, and the RX FIFO is empty. • In I²C master transmitter mode, the I2C<i>i</i>.I²C_CON[1] STP bit is set to 1 and the I2C<i>i</i>.I²C_CNT[15:0] DCOUNT bit field value is 0. • In I²C master transmitter mode, the I2C<i>i</i>.I²C_CON[1] STP bit is cleared to 0 and the I2C<i>i</i>.I²C_CNT[15:0] DCOUNT bit field value passed 0. • In I²C master receiver mode, the I2C<i>i</i>.I²C_CON[1] STP bit is set to 1, the I2C<i>i</i>.I²C_CNT[15:0] DCOUNT field value passed 0, and the RX FIFO is empty. • In I²C slave transmitter mode, a stop(P) or start (S) condition is received from the external I²C master device. • In I²C slave receiver mode, a stop(P) or start (S) condition is received from the external I²C master device and the RX FIFO is empty. • In SCCB master transmitter or receiver mode, a stop (P) condition is detected.
RRDY event	I ² C receive mode and SCCB read mode	I2C <i>i</i> .I ² C_STAT[3] RRDY	I2C <i>i</i> .I ² C_IE[3] RRDY_IE	The RX FIFO level is above the threshold (I2C <i>i</i> .I ² C_BUF[13:8] RTRSH bit field value + 1).
XRDY event	I ² C transmit mode and SCCB write mode	I2C <i>i</i> .I ² C_STAT[4] XRDY	I2C <i>i</i> .I ² C_IE[4] XRDY_IE	The module requires new data to be served. A master transmitter module requests new data when the TX FIFO level is below the threshold (I2C <i>i</i> .I ² C_BUF[5:0] XTRSH bit field value + 1) and the required amount of data to be transmitted specified by the I2C <i>i</i> .I ² C_BUFSIZE[5:0] TXSTAT bit field is greater than the threshold. A slave transmitter requests new data when the TX FIFO is below the threshold (if the I2C <i>i</i> .I ² C_BUF[5:0] XTRSH bit field value is greater than 1), or when there is a read request from the external master device (for each acknowledge received from the master) when the I2C <i>i</i> .I ² C_BUF[5:0] XTRSH bit field value is 1.
GC event	I ² C mode only	I2C <i>i</i> .I ² C_STAT[5] GC	I2C <i>i</i> .I ² C_IE[5] GC_IE	The module detects a general call on the I ² C bus (all bits of the address cleared to 0).

Table 17-9. HS I²C Interrupt Events (continued)

Event Name	Supported Configuration Mode	Status Bit	Mask Bit	This Event Happens When:
STC event	I ² C mode only	I2Ci.I2C_STAT[6] STC	I2Ci.I2C_IE[6] STC_IE	The module is in idle mode and a start (S) condition is asynchronously detected on the I ² C bus and signaled with a wakeup. When the active mode is restored and the interrupt generated, this bit indicates the reason for the wakeup. ⁽¹⁾
AERR event	I ² C and SCCB modes	I2Ci.I2C_STAT[7] AERR	I2Ci.I2C_IE[7] AERR_IE	A write access to the I2Ci.I2C_DATA register by the LH through the L4-Core interconnect is performed while the TX FIFO is full or a read access to the I2Ci.I2C_DATA register by the LH through the L4-Core interconnect is performed while the RX FIFO is empty. When the RX FIFO is empty, the read of the RX FIFO returns the previous read data value. When the TX FIFO is full, a write in the TX FIFO is ignored.
BF event	I ² C and SCCB modes	I2Ci.I2C_STAT[8] BF	I2Ci.I2C_IE[8] BF_IE	The I ² C bus becomes free (after a transfer is ended on the bus and a stop [P] condition is detected).
AAS event	I ² C mode only	I2Ci.I2C_STAT[9] AAS	I2Ci.I2C_IE[9] AAS_IE	The module has recognized its own slave address or an alternate Own Address, or a general call (all address bits cleared to 0).
XUDF event	I ² C and SCCB transmit mode	I2Ci.I2C_STAT[10] XUDF	I2Ci.I2C_IE[10] XUDF_IE	The module has recognized a transmission underflow interrupt event.
ROVR event	I ² C and SCCB receive mode	I2Ci.I2C_STAT[11] ROVR	I2Ci.I2C_IE[11] ROVR_IE	The module has recognized an overrun event on the receiving line.
RDR event	I ² C receive mode only	I2Ci.I2C_STAT[13] RDR	I2Ci.I2C_IE[13] RDR_IE	The module is configured as a receiver, a stop (P) condition was received on the I ² C bus, and the RX FIFO level is below the threshold (I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1).
XDR event	I ² C master transmit mode only	I2Ci.I2C_STAT[14] XDR	I2Ci.I2C_IE[14] XDR_IE	The module is configured as a master transmitter, the TX FIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH bit field value + 1), and the amount of data still to be transferred is less than this threshold.

⁽¹⁾ The interrupt request generation on an STC event must be enabled only if the module is configured to allow the possibility of switching off the functional clock while in IDLE state (the I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY bit field set to b00 or b01). The first transfer (corresponding to the detected start [S] condition) is lost, and is used only to restore the active mode of the module. On the I²C bus, the external master that generated the transfer detects this behavior as a nonacknowledge to the address phase and may possibly restart the transfer.

When an interrupt request is generated, software must read the I2Ci.I2C_STAT register to check which event caused the interrupt request generation, process accordingly, and acknowledge each processed event by writing 1 to the corresponding bit in the I2Ci.I2C_STAT register.

NOTE: The I2Ci.I2C_STAT[9] AAS status bit, corresponding to the AAS event, can be cleared in two ways:

- If the I2Ci.I2C_IE[9] AAS_IE bit is set to 1 (interrupt generation enabled), the status bit is cleared by writing 1 to the I2Ci.I2C_STAT[9] AAS status bit.
- If the I2Ci.I2C_IE[9] AAS_IE bit is cleared to 0 (interrupt generation disabled), the status bit is cleared when a new start(S) or stop (P) condition is detected on the I²C bus.

17.4 HS I²C Functional Description

17.4.1 HS I²C Block Diagram

Figure 17-21 is a functional block diagram of the HS I²C controllers.

Figure 17-21. HS I²C Controllers Functional Block Diagram

NOTE: The i2c1_sccbe and i2c4_sccbe signal is not available. The i2c4 does not have SWAKEUP request. It also gets its RESET signal from the PRCM reset manager.

The three HS I²C controllers can be configured in F/S I²C mode, in HS I²C mode, or in SCCB mode. The operation mode is selected by configuring the I2Ci.I2C_CON[13:12] OPMODE bit field. Table 17-10 lists the available operation modes.

Table 17-10. HS I²C Operation Mode Selection

Operation Mode	I2C.I2C_CON[13:12] OPMODE Bit Field Value
F/S I ² C	0x0
HS I ² C	0x1
SCCB	0x2
Reserved (not used)	0x3

17.4.2 HS I²C Transmit Mode in I²C Mode

This mode is available for master or slave. The master and slave modes are configurable with the I2Ci.I2C_CON[10] MST bit (0: slave mode; 1: master mode).

In master mode, the transmit mode is configured by setting the I2Ci.I2C_CON[9] TRX bit to 1. The MPU subsystem puts the data to transmit in the TX FIFO by writing to the I2Ci.I2C_DATA[7:0] DATA bit field.

The transmitter can write new data to this register when the I2Ci.I2C_STAT[4] XRDY bit is set to 1, or when the I2Ci.I2C_STAT[14] XDR bit is set to 1 according to the draining mechanism description.

A master transmitter requests new data if the I2Ci.I2C_CNT[15:0] DCOUNT bit field value is not 0. A slave transmitter requests new data if a read is performed by the external master.

NOTE: The HS I²C4 is configured in master transmitter mode, and its configuration cannot be changed.

17.4.3 HS I²C Receive Mode in I²C Mode

This mode is available for master or slave mode. In master mode, it is configured by clearing the I2Ci.I2C_CON[9] TRX bit to 0.

The MPU subsystem can read new data from the I2Ci.I2C_DATA[15:0] DCOUNT bit field when the I2Ci.I2C_STAT[3] RRDY bit is set to 1, or when the I2Ci.I2C_STAT[13] RDR bit is set according to the description of the draining mechanism.

Each time the I2Ci.I2C_STAT[3] RRDY bit is set to 1, if the interrupt is enabled (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1), the I²C controller generates an interrupt to the MPU subsystem.

NOTE: In interrupt mode, the MPU subsystem must read this bit after each read in the I2Ci.I2C_DATA register to ensure that no other data is waiting for the FIFO to be read. For a new interrupt to be received, the I2Ci.I2C_STAT[3] RRDY bit must be cleared in the interrupt routine.

If the DMA receive mode is enabled (the I2Ci.I2C_BUF[15] RDMA_EN bit is set), this bit is forced to 0 and no interrupt is generated; instead, a DMA RX request to the sDMA controller is generated.

17.4.4 HS I²C FIFO Management

Each HS I²C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs. The FIFOs are fully configurable / controllable to deliver their carried signals to the targeted sink with maximum signal integrity. Configuration of the buffers is done by groups assignment and not individually per pad; each group is assigned a specific prg_xxx register inside the System Control Module. Refer to [Chapter 13, System Control Module](#).

[Table 17-11](#) lists the depth of these FIFOs, depending on the instance of the I²C controller.

Table 17-11. HS I²C RX and TX FIFO Depths

I ² C Controller Instance	RX and TX FIFO Depth (in bytes)
I2C1	8
I2C2	8
I2C3	64

The depth of the RX and TX FIFOs can be checked by reading the I2Ci.I2C_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

17.4.4.1 HS I²C FIFO Interrupt Mode Operation

In FIFO interrupt mode (relevant interrupts enabled by the I2Ci.I2C_IE register), the processor is informed of the receiver and transmitter status by an interrupt signal. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1 for the RX FIFO or the I2Ci.I2C_BUF[5:0] XTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I²C controller in receive mode and/or from any source to the HS I²C controller FIFO in transmit mode).

Figure 17-22 and Figure 17-23 show receive and transmit operations, respectively, from a FIFO management point of view.

Figure 17-22. HS I²C Receive FIFO Interrupt Request Generation

In Figure 17-22, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the I2Ci.I2C_STAT[3] RRDY bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

NOTE: In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C_BUF[13:8] RTRSH and I2Ci.I2C_BUF[5:0] XTRSH bit fields to 0x0.

Figure 17-23. HS I²C Transmit FIFO Interrupt Request Generation

In [Figure 17-23](#), the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by writing 1 in the I²C_i.I²C_STAT[4] XRDY bit after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY/RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is no longer met.
- When detecting an interrupt request (XRDY/RRDY type), the LH can be programmed to write/read the number of data bytes specified by the corresponding FIFO threshold (the I²C_i.I²C_BUF[5:0] XTRSH bit field value + 1 for the TX threshold or the I²C_i.I²C_BUF[13:8] RTRSH bit field value + 1 for the RX threshold). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY/RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see [Section 17.4.4.4, HS I²C Draining Feature \(I²C Mode Only\)](#).

NOTE: In slave transmit mode (the I²C_i.I²C_CON[10] MST bit is cleared and the I²C_i.I²C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I²C bus. In this case, the TX FIFO must be cleared by setting the I²C_i.I²C_BUF[6] TXFIFO_CLR bit.

17.4.4.2 HS I²C FIFO Polling Mode Operation

In FIFO polled mode (the I²C_i.I²C_IE[4] XRDY_IE and I²C_i.I²C_IE[3] RRDY_IE bits are disabled, and the I²C_i.I²C_BUF[15] RDMA_EN and I²C_i.I²C_BUF[7] XDMA_EN bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I²C_i.I²C_STAT[4] XRDY and the I²C_i.I²C_STAT[3] RRDY bits (the I²C_i.I²C_STAT[13] RDR and I²C_i.I²C_STAT[14] XDR bits can also be polled if the draining feature is enabled). The I²C_i.I²C_STAT[4] XRDY and I²C_i.I²C_STAT[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of the FIFO interrupt mode operation.

17.4.4.3 HS I²C FIFO DMA Mode Operation (I²C Mode Only)

In receive mode, a DMA request is generated by the I²C_DMA_RX signal as soon as the RX FIFO exceeds its threshold level (the I²C_i.I²C_BUF[13:8] RTRSH bit field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the sDMA controller.

[Figure 17-24](#) shows the DMA request generation in receive mode.

Figure 17-24. HS I²C Receive FIFO DMA Request Generation

In transmit mode, a DMA request is automatically asserted by the I2Ci_DMA_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (the I2Ci.I2C_BUF[5:0] XTRSH bit field value + 1) is written in the FIFO by the sDMA controller. If an insufficient number of bytes is written, the DMA request remains active. [Figure 17-25](#) and [Figure 17-26](#) show the DMA TX transfers with different values for the I2Ci.I2C_BUF[5:0] XTRSH bit field.

Figure 17-25. HS I²C Transmit FIFO Request Generation (High Threshold)

Figure 17-26. HS I²C Transmit FIFO Request Generation (Low Threshold)

NOTE: In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C_BUF[13:8] RTRSH and I2Ci.I2C_BUF[5:0] XTRSH bit fields to 0x0.

The I²C module allows the user to clear the RX or TX FIFO by setting the I2Ci.I2C_BUF[14] RXFIFO_CLR and I2Ci.I2C_BUF[6] TXFIFO_CLR bits, which act like software reset for the FIFOs. In DMA mode, these bits also reset the DMA state-machines. The FIFO clearing feature can be used when the following conditions are met:

- The module is configured as a transmitter.
- The external receiver responds with a NACK in the middle of the transfer.
- Data in the TX FIFO are still waiting to be transferred.

17.4.4.4 HS I²C Draining Feature (I²C Mode Only)

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1 for the RX threshold and the I2Ci.I2C_BUF[5:0] XTRSH bit field value + 1 for the TX threshold). It also offers the possibility of transferring the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the sDMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2Ci.I2C_STAT[7] AERR bit.

The draining mechanism generates an interrupt using the I2Ci.I2C_STAT[13] RDR or the I2Ci.I2C_STAT[14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT or I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1) is not reached, but the transfer ends on the I²C bus and there is still data in the RX FIFO (less than the threshold), the receive draining interrupt (the I2Ci.I2C_STAT[13] RDR bit) is asserted to inform the LH that it can read the amount of data in the FIFO (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit field). The LH performs a number of data read accesses equal to the value of the I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit field value (interrupt or polling mode), or reconfigures the sDMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (the I2Ci.I2C_BUF[5:0] XTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2Ci.I2C_STAT[14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit field). The LH must write the required number of data bytes specified by the value of the I2Ci.I2C_BUFSTAT[5:0] TXSTAT field value or reconfigure the sDMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately skip the checking of the value of the I2Ci.I2C_BUFSTAT[5:0] TXSTAT and I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit fields, because it can obtain this information internally (by computing the value of the I2Ci.I2C_CNT[15:0] DATACOUNT bit field modulo I2Ci.I2C_BUF[13:8] RTRSH or I2Ci.I2C_BUF[5:0] XTRSH).

By default, the draining feature is disabled; it can be enabled using the I2Ci.I2C_IE[14] XDR_IE or I2Ci.I2C_IE[13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (the I2Ci.I2C_BUF[5:0] XTRSH bit field value + 1 for the TX threshold or the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1 for the RX threshold).

17.4.5 HS I^C Programmable Multislave Channel Feature (I^C Mode Only)

This feature allows each HS I^C controller to be addressed using four separate Own Addresses configured in the I2Ci.I2C_OAx registers (where x = 0, 1, 2, 3). An additional register (I2Ci.I2C_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I^C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2Ci.I2C_CON[7] XOA0, I2Ci.I2C_CON[6] XOA1, I2Ci.I2C_CON[5] XOA2, or I2Ci.I2C_CON[4] XOA3).

17.4.6 HS I^C Automatic Blocking of the I^C Clock Feature (I^C Mode Only)

This feature offers the possibility for the LH to command the blocking of the I^C clock after the slave addressing phase, when the I^C controller is addressed by an external master device using a certain Own Address.

The release of the I^C clock (i2ci_scl signal, where i = 1, 2, 3) can be performed independently for each Own Address (I2Ci.I2C_OAi registers, where i = 0, 1, 2, 3) by deasserting the corresponding bit in the I2Ci.I2C_SBLOCK register.

17.4.7 HS I^C Clocking

Figure 17-27 shows the I^C clock generation of the HS I^C controllers.

Figure 17-27. HS I^C Clock Generation

Each HS I^C controller uses the I2Ci_FCLK functional clock in the PRCM module. The internal sampling clock I2Ci_INTERNAL_CLK is generated by dividing the functional clock by (the I2Ci.I2C_PSC[7:0] PSC bit field value + 1) in F/S mode, in SCCB mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the I2Ci_SCL signal is determined by the I2Ci.I2C_SCL[7:0] SCLL bit field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C_SCL[15:8] HSSCLL bit field in the second phase of HS mode.

The high time of the I²C_i_SCL signal is determined by the I²C_i.I²C_SCLH[7:0] SCLH bit field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I²C_i.I²C_SCLH[15:8] HSSCLH bit field in the second phase of HS mode.

Table 17-12 lists the t_{LOW} and t_{HIGH} values in master mode only (in slave mode, the I²C controller does not generate the I²C clock).

Table 17-12. HS I²C t_{LOW} and t_{HIGH} Values of the I²C Clock

Mode	I ² C_INTERNAL_CLK	t _{Low}	t _{HIGH}
F/S, SCCB, or HS first phase	I ² C _i _INTERNAL_CLK = I ² C _i _FCLK / (I ² C _i .I ² C_PSC[7:0] PSC bit field + 1)	(I ² C _i .I ² C_SCLH[7:0] SCLL bit field value + 7) x I ² C _i _INTERNAL_CLK period	(I ² C _i .I ² C_SCLH[7:0] SCLH bit field value + 5 + t _{delay} ⁽¹⁾) x I ² C _i _INTERNAL_CLK period
HS second phase	I ² C _i _FCLK	(I ² C _i .I ² C_SCLH[15:8] HSSCLL bit field value + 7) x I ² C _i _INTERNAL_CLK period	(I ² C _i .I ² C_SCLH[15:8] HSSCLH bit field value + 5 + t _{delay} ⁽¹⁾) x I ² C _i _INTERNAL_CLK period

⁽¹⁾ t_{delay} = Internal propagation delay for I²C_i_SCL to consider process dispersion and voltage and temperature variations (PVT)
t_{delay} (min) = floor(36 ns/(I²C_i_INTERNAL_CLK period))
t_{delay} (max) = floor(117 ns/(I²C_i_INTERNAL_CLK period))

NOTE: The equations in Table 17-12 give the SCL timing values for SCLL/SCLH/HSSCLL/HSSCLH at HS I²C controller outputs. Actual t_{low} and t_{high} periods may vary, depending on the board (the load capacitance on the SCL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board

NOTE: For HS mode, the I²C_i.I²C_SCLL[15:8] HSSCLL and I²C_i.I²C_SCLL[7:0] SCLL bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, the I²C_i.I²C_SCLH[15:8] HSSCLH and I²C_i.I²C_SCLH[7:0] SCLH bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

CAUTION

During active mode (the I²C_i.I²C_CON[15] I²C_EN bit is set to 1), make no changes to the I²C_i.I²C_SCLL and I²C_i.I²C_SCLH registers. Changes may result in unpredictable behavior.

NOTE: Each HS I²C controller can be used with an internal secondary pullup. This pullup is mandatory when the I²C controller is configured in HS mode for a bit rate of 3.4 Mbps, and the bus line capacitance exceeds 45 pF. Pullups can be programmed through the CONTROL.CONTROL_PROG_IO1[19] PRG_I2C1_PULLUPRESX bit for I²C1, the CONTROL.CONTROL_PROG_IO1[0] PRG_I2C2_PULLUPRESX bit for I²C2, and the CONTROL.CONTROL_PROG_IO2[7] PRG_I2C3_PULLUPRESX bit for I²C3.

The maximum bit rate specified by the SCCB specifications is 100 Kbps.

17.4.8 HS I²C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S and SCCB operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the I²C_i_INTERNAL_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For SCCB modes (for example, the I2Ci.I2C_PSC[7:0] PSC bit field = 4), the maximum width of suppressed spikes is 52 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the 2Ci.I2C_PSC[7:0] PSC bit field.

17.4.9 HS I²C System Test Mode

A system test mode is available for the HS I²C controller module testing. This mode is enabled by setting the I2Ci.I2C_SYSTEST[15] ST_EN to 1. When this bit is cleared to 0, the I²C controller is configured in normal operation mode.

In system test mode, the I2Ci_SYSTEST[13:12] TMODE bit field selects the type of test. [Table 17-14](#) lists the tests available for the HS I²C controllers.

Table 17-13. HS I²C List of tests for the HS I²C Controllers

I2Ci.I2C_SYSTEST[13:12]] TMODE Bit Field Value	Test	Description
b00	Functional mode	Normal operation mode
b01	Reserved (not used)	
b10	Test of i2ci_scl serial clock line	The i2ci_scl line is driven with a permanent clock as if mastered with the parameters set in the I2Ci.I2C_PSC, I2Ci.I2C_SCLL, and I2Ci.I2C_SCLH registers.
b11	Loop-back mode + i2ci_scl/ i2ci_sda/ i2ci_sccbe input/output	In the master transmit mode only, data transmitted out of the I2Ci.I2C_DATA register (write action) is received in the same I2Ci.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2ci_scl, i2ci_sda, and i2ci_sccbe lines are controlled with the I2Ci.I2C_SYSTEST[4:0] bits.

NOTE: When the I2Ci.I2C_SYSTEST[13:12] TMODE bit field = b11, the I²C controller must be configured in I²C F/S mode (I2Ci.I2C_CON[13:12] OPMODE = b00) or I²C HS mode (I2Ci.I2C_CON[13:12] OPMODE = b01). The loop-back mode is not available in SCCB mode (I2Ci.I2C_CON[13:12] OPMODE = b10).

NOTE: In normal operation mode (I2Ci.I2C_SYSTEST[15] ST_EN clear to 0), the I2Ci.I2C_SYSTEST[4:0] bits that control the i2ci_scl, i2ci_sda, and i2ci_sccbe lines in system test mode are read-only bits.

In system test mode (the I2Ci.I2C_SYSTEST[15] ST_EN bit set to 1), the I2Ci.I2C_STAT[5:0] status bits can be set to 1 when the I2Ci.I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2Ci.I2C_SYSTEST[11] SSB bit to 0 does not clear the I2Ci.I2C_STAT[5:0] status bits to 0. The I2Ci.I2C_STAT[5:0] status bits can be cleared to 0 only by writing 1 in the corresponding bits. In addition to the test modes, this actual data can be polled to see what is being inputted and outputted on the two clock and data lines. These tests are only available in functional mode. [Table 17-14](#) lists the data polling tests.

Table 17-14. HS I²C List of Data In/Out Checks

I2Ci.I2C_SYSTEST Bit Field	Test	Description
[8] SCL_I_FUNC	SCL line input value	Testing/reading incoming 1 or 0 on the clock line
[7] SCL_O_FUNC	SCL line output value	Testing/reading outgoing 1 or 0 on the clock line
[6] SDA_I_FUNC	SDA line input value	Testing/reading incoming 1 or 0 on the data line
[5] SDA_O_FUNC	SDA line output value	Testing/reading outgoing 1 or 0 on the data line

17.4.10 HS I²C Write and Read Operations in SCCB Mode

In SCCB mode, the HS I²C controller can write or read a single byte to or from the external SCCB device.

To write a single byte to the external SCCB device, the HS I²C controller must be configured in multimaster transmitter mode by setting the I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits to 1. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C_OA register. The 8-bit data to be transmitted is written by the LH in the I2Ci.I2C_DATA register.

To read a single byte from the external SCCB device, the HS I²C controller must be configured in multimaster receiver mode by setting the I2Ci.I2C_CON[10] MST to 1 and by clearing the I2Ci.I2C_CON[9] TRX bit to 0. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C_OA register. The 8-bit data received from the external SCCB device is read by the LH from the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the RX and TX thresholds must be set to 1 by configuring the I2Ci.I2C_BUF[13:8] RTRSH and I2Ci.I2C_BUF[5:0] XTRSH bit fields to 0x0.

17.4.11 HS I²C Power Chip Communication Operations

The master transmitter HS I²C controller I2C4 inside the voltage controller of the PRM module is used to send configuration commands from the LH to external power chip(s).

For voltage control operations, the LH must set the slave address of the first power chip in the PRCM.PRM_VC_SMPS_SA[6:0] SA0 bit field, and the slave address of the second power chip (if necessary) in the PRCM.PRM_VC_SMPS_SA[22:16] SA1 bit field.

The LH must also configure the specific registers in the voltage controller of the PRCM module, for the voltage control and power-sequencing functions.

A high-priority bypass mode is available to allow the LH to configure the external power chip(s) through the I²C bus. To write 8-bit data to the configuration registers of an external power chip, the LH must set the 7-bit external power chip slave address in the PRCM.PRM_VC_BYPASS_VAL[6:0] SLAVEADDR bit field, the configuration register address in the PRCM.PRM_VC_BYPASS_VAL[15:8] REGADDR bit field, and the 8-bit data in the PRCM.PRM_BYPASS_VAL[23:16] bit field.

For details about voltage control, see [Chapter 3, Power, Reset, and Clock Management](#).

17.5 HS I²C Basic Programming Model

17.5.1 HS I²C Controller Basic Programming Model in I²C Mode

This section describes the programming model of the multimaster HS I²C controllers configured in I²C mode.

17.5.1.1 HS I²C Main Program (I²C Mode)

17.5.1.1.1 HS I²C Configure the Module Before Enabling the I²C Controller (I²C Mode)

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Section 17.3.1.1.1, HS I²C Module Clocks](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (I2Ci_INTERNAL_CLK) by programming the corresponding value in the I2Ci.I2C_PSC[3:0] PSC bit field. This value depends on the frequency of the functional clock (I2Ci_FCLK). Because this frequency is 96 MHz, the value of the I2Ci.I2C_PSC[7:0] PSC bit field is 0x7.
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH bit fields to obtain a bit rate of 100 Kbps or 400 Kbps. These values depend on the internal sampling clock frequency (see [Table 17-12](#)).

4. (Optional) Program the I²C_i.I²C_SCLL[15:8] HSSCLL and I²C_i.I²C_SCLH[15:8] HSSCLH bit fields to obtain a bit rate of 400 Kbps or 3.4 Mbps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see [Table 17-12](#)).
5. (Optional) If a bit rate of 3.4 Mbps is used and the bus line capacitance exceeds 45 pF, program the CONTROL.CONTROL_PROG_IO1[19] PRG_I2C1_PULLUPRESX bit for I²C1, the CONTROL.CONTROL_PROG_IO1[0] PRG_I2C2_PULLUPRESX bit for I²C2, or the CONTROL.CONTROL_PROG_IO2[7] PRG_I2C3_PULLUPRESX bit for I²C3.
6. Configure the Own Address of the I²C controller by storing it in the I²C_i.I²C_OA register. Up to four Own Addresses can be programmed in the I²C_i.I²C_OAi registers (where i = 0, 1, 2, 3) for each I²C controller.

NOTE: For a 10-bit address, set the corresponding expand Own Address bit in the I²C_i.I²C_CON register.

7. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I²C_i.I²C_BUF[5:0] XTRSH field to (TX threshold –1) and the I²C_i.I²C_BUF[13:8] RTRSH bit field to (RX threshold –1), where the TX and RX thresholds are greater than or equal to 1.
8. Take the I²C controller out of reset by setting the I²C_i.I²C_CON[15] I²C_EN bit to 1.

17.5.1.1.2 HS I²C Initialize the I²C Controller (I²C Mode)

To initialize the HS I²C controller, perform the following steps:

1. Configure the I²C_i.I²C_CON register:
 - For master or slave mode, set the I²C_i.I²C_CON[10] MST bit (0: slave; 1: master).
 - For transmitter or receiver mode, set the I²C_i.I²C_CON[9] TRX bit (0: receiver; 1: transmitter).
2. For a module that should work in master mode, set the CONTROL.CONTROL_PADCONF_x INPUTENABLE bit for the corresponding I²C module to achieve the synchronous clock on the clock output.
3. If using an interrupt to transmit/receive data, set the corresponding bit in the I²C_i.I²C_IE register to 1 (the I²C_i.I²C_IE[4] XRDY_IE bit for the transmit interrupt, the I²C_i.I²C_IE[3] RRDY_IE bit for the receive interrupt). Also, if needed enable the I²C_i.I²C_IE[11] ROVR_IE bit for receiving start of draining on the internal FIFO interrupt. If using the HS I²C for transmitter the I²C_i.I²C_IE[10] XUDF_IE for interrupting if underflow occurs on the internal FIFO.
4. If using DMA to receive/transmit data, set the corresponding bit in the I²C_i.I²C_BUF register to 1 (the I²C_i.I²C_BUF[15] RDMA_EN bit for the receive DMA channel, the I²C_i.I²C_BUF[7] XDMA_EN bit for the transmit DMA channel).

17.5.1.1.3 HS I²C Configure Slave Address and the Data Control Register (I²C Mode)

In master mode, configure the slave address register by programming the I2Ci.I2C_SA[9:0] SA bit field and the number of data bytes (I²C data payload) associated with the transfer by programming the I2Ci.I2C_CNT[15:0] DCOUNT bit field.

NOTE: For a 10-bit address, set the I2Ci.I2C_CON[8] XSA bit to 1.

17.5.1.1.4 HS I²C Initiate a Transfer (I²C Mode)

Poll the I2Ci.I2C_STAT[12] BB bit. If it is cleared to 0 (bus not busy), configure the I2Ci.I2C_CON[0] STT and I2Ci.I2C_CON[1] STP bits. To initiate a transfer, the I2Ci.I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2Ci.I2C_CON[1] STP bit to 1.

17.5.1.1.5 HS I²C Receive Data (I²C Mode)

Poll the I2Ci.I2C_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1) or the DMA RX channel (the I2Ci.I2C_BUF[15] RDMA_EN bit must be set to 1) to read the receive data in the I2Ci.I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (the I2Ci.I2C_BUF[13:8] RTRSH bit field + 1), use the draining feature (enable the RDR interrupt by setting the I2Ci.I2C_IE[13] RDR_IE bit to 1).

NOTE: In receive mode only, the I2Ci.I2C_STAT[11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I²C controller simply holds the serial clock line i2ci_scl to low to prevent other bytes from being received.

The I2Ci.I2C_STAT[7] AERR bit is set to 1 when a read access is performed in the I2Ci.I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IE[7] AERR_IE bit to 1.

17.5.1.1.6 HS I²C Transmit Data (I²C Mode)

Poll the I2Ci.I2C_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IE[4] XRDY_IE bit must be set to 1) or the DMA TX channel (the I2Ci.I2C_BUF[7] XDMA_EN bit must be set to 1) to write data to the I2Ci.I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (the I2Ci.I2C_BUF[5:0] XTRSH bit field + 1), use the draining feature (enable the XDR interrupt by setting the I2Ci.I2C_IE[14] XDR_IE bit to 1).

NOTE: In transmit mode only, the I2Ci.I2C_STAT[10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the I2Ci.I2C_CNT[15:0] DCOUNT bit field value is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I²C master device still requests data bytes to be read.

The I2Ci.I2C_STAT[7] AERR bit is set to 1 when a write access is performed in the I2Ci.I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IE[7] AERR_IE bit to 1.

Underflow interrupt on the FIFO can be also enabled from the I2Ci.I2C_IE[10] XUDF_IE bit.

17.5.1.2 HS I²C Interrupt Subroutine Sequence (I²C Mode)

Perform the following steps:

1. Test for arbitration lost (the I2Ci.I2C_STAT[0] AL "status" bit) and resolve accordingly.
2. Test for no acknowledgment (the I2Ci.I2C_STAT[1] NACK "status" bit) and resolve accordingly.
3. Test for register access ready (the I2Ci.I2C_STAT[2] ARDY "status" bit) and resolve accordingly.
4. Test for receive data ready (the I2Ci.I2C_STAT[3] RRDY "status" bit) and resolve accordingly.
5. Test for transmit data ready (the I2Ci.I2C_STAT[4] XRDY "status" bit) and resolve accordingly.
6. Test for general call (the I2Ci.I2C_STAT[5] GC "status" bit) and resolve accordingly.
7. Test for start (S) condition (the I2Ci.I2C_STAT[6] STC "status" bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2Ci.I2C_STAT[7] AERR "status" bit) and resolve accordingly.
9. Test for bus free (the I2Ci.I2C_STAT[8] BF "status" bit) and resolve accordingly.

17.5.1.3 HS I²C Programming Flow Diagrams (I²C Mode)

Figure 17-28 through Figure 17-36 are procedure flow charts for programming the I²C F/S and HS modes.

Figure 17-28. HS I²C Mode Setup Procedure (I²C Mode)

i2c-035

- (1) The NACK, AL, ARDY and RDR bits are cleared by writing 1 to each corresponding bit in the I²C_i.I²C_STAT register.
- (2) In slave transmitter mode, the amount of data requested by the external master I²C device is unknown; thus, the I²C_i.I²C_BUFBUF[5:0] XTRSH bit field must be configured to 0x0 (TX threshold = 1).

Figure 17-36. HS I²C Slave Transmitter/Receiver Mode, Interrupt (I²C Mode)

i2c-036

- (1) The XRDY, RDR, RRDY, and ARDY bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C_STAT register.
- (2) In slave transmitter mode, the amount of data requested by the external master I²C device is unknown; thus, the I2Ci.I2C_BUF[5:0] XTRSH bit field must be configured to 0x0 (TX threshold = 1).

17.5.2 HS I²C Controller Basic Programming Model in SCCB Mode

This section describes the programming model of the multimaster HS I²C controllers configured in SCCB mode.

17.5.2.1 HS I²C Main Program (SCCB Mode)

17.5.2.1.1 HS I²C Configure the Module Before Enabling the I²C Controller (SCCB Mode)

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Section 17.3.1.1.1, HS I²C Module Clocks](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (the I2Ci_INTERNAL_CLK) by programming the corresponding value in the I2Ci.I2C_PSC[7:0] PSC bit field. This value depends on the frequency of the functional clock (the I2Ci_FCLK). Because this frequency is 96 MHz, the value of I2Ci.I2C_PSC[7:0] PSC bit field is 0x7.
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH bit fields to obtain a bit rate of 100 Kbps (maximum authorized bit rate in SCCB mode). This value depends on the internal sampling clock frequency (see [Table 17-12](#)).
4. Configure the 7-bit slave address (ID value) by storing it in the I2Ci.I2C_SA register.

5. Configure the 8-bit register address (subaddress) by storing it in the I2Ci.I2C_OA0 register.
6. Configure the I2Ci.I2C_BUF[13:8] RTRSH bit field to 0x0 (RX threshold to 1) and the I2Ci.I2C_BUF[5:0] XTRSH bit field to 0x0 (TX threshold to 1).
7. Take the I²C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

17.5.2.1.2 HS I²C Initialize the I²C Controller (SCCB Mode)

To initialize the I²C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:
 - In SCCB mode, only the master mode is supported; set the I2Ci.I2C_CON[10] MST bit to 1.
 - For transmitter mode (write to the external SCCB device register) or receiver mode (read from the external SCCB device register), set the I2Ci.I2C_CON[9] TRX bit (0: receiver; 1: transmitter).
2. Set the CONTROL.CONTROL_PADCONF_x.INPUTENABLE bit for the corresponding I²C module to achieve the synchronous clock on the clock output.
3. If using an interrupt to transmit/receive data, set the corresponding bit in the I2Ci.I2C_IE register to 1 (the I2Ci.I2C_IE[4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IE[3] RRDY bit for the receive interrupt). Also, if needed enable the I2Ci.I2C_IE[11] ROVR_IE bit for receiving start of draining on the internal FIFO interrupt. If using the HS I²C for transmitter the I2Ci.I2C_IE[10] XUDF_IE bit for interrupting if underflow occurs on the internal FIFO.

17.5.2.1.3 HS I²C Initiate a Transfer (SCCB Mode)

Poll the I2Ci.I2C_STAT[12] BB bit. If it is cleared to 0 (bus not busy), set the I2Ci.I2C_CON[0] STT bit to 1. Because a transfer allows the LH to write or read only a single byte to or from the external SCCB device, the transmission automatically stops at the end of the transfer. When the transfer completes, the I2Ci.I2C_STAT[2] ARDY bit is set to 1. In SCCB mode, the I2Ci.I2C_CON[1] STP bit is not used.

17.5.2.1.4 HS I²C Receive Data (SCCB Mode)

Poll the I2Ci.I2C_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1) to read the receive data in the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the I2Ci.I2C_BUF[13:8] RTRSH bit field (RX threshold) must be set to a value of 0x0 (RX threshold = 1).

17.5.2.1.5 HS I²C Transmit Data (SCCB Mode)

Poll the I2Ci.I2C_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IE[4] XRDY_IE bit must be set to 1) to write the data to the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the I2Ci.I2C_BUF[5:0] XTRSH bit field (TX threshold) must be set to a value of 0x0 (TX threshold = 1).

17.5.2.2 HS I²C Interrupt Subroutine Sequence (SCCB Mode)

Perform the following steps:

1. Test for register access ready (the I2Ci.I2C_STAT[2] ARDY status bit) and resolve accordingly.
2. Test for receive data ready (the I2Ci.I2C_STAT[3] RRDY status bit) and resolve accordingly.
3. Test for transmit data ready (the I2Ci.I2C_STAT[4] XRDY status bit) and resolve accordingly.

17.5.2.3 HS I²C Programming Flow Diagrams (SCCB Mode)

Figure 17-37 through Figure 17-41 are procedure flow charts for programming the SCCB mode.

NOTE: The RRDY and ARDY bits are cleared by writing 1 in the corresponding bit in the I2Ci.I2C_STAT register.

17.5.3 HS I²C Controller I²C4 Basic Programming Model for Communication With Power Chips

This section describes the programming model of master transmitter HS I²C4 for communication with one or more power chips. I²C4 allows the two voltage finite state machines (FSMs) in the PRCM module of the device to be interfaced to external power chips through the I²C bus for dynamic voltage control of two power supplies and power sequencing. The primary programming tasks are to set up the configuration registers according to the external power supply chip(s) being used.

17.5.3.1 HS I²C Configure the Voltage Controller Registers

To use the voltage control function, the LH must configure the following registers in the voltage controller of the PRCM module:

- The voltage configuration register address for each VDD channel in the PRCM.PRM_VC_SMPS_RA register
- The ON/ON-low-power-Retention/OFF command configuration register address for each VDD channel in the PRCM.PRM_VC_SMPS_CMD_RA register
- The set of ON/ON-low-power/Retention/OFF voltage/mode values in the PRCM.
PRM_VC_CMD_VAL_0 register for the first VDD channel and the PRCM.
PRM_VC_CMD_VAL_1 register for the second VDD channel
- The VDD channels configuration selection in the PRCM.PRM_VC_CH_CONF register

For details about voltage controller register configuration, see [Chapter 3, Power, Reset, and Clock Management](#).

17.5.3.2 HS I²C Configure the HS I²C4

At power-on reset (PoR), the I²C4 is in HS mode (the PRCM.PRM_VC_I²C_CFG[3] HSEN bit). In HS mode, the LH must configure the master code value for the preamble I²C HS transmission by configuring the PRCM.PRM_VC_I²C_CFG[2:0] MCODE bit field. If the external power chips do not support the I²C HS mode, the HS mode can be disabled and F/S mode enabled by clearing the PRCM.PRM_VC_I²C_CFG[3] HSEN bit to 0.

By default, the repeated start operation is enabled (the PRCM.PRM_VC_I²C_CFG[4] SREN bit is set to 1 at PoR). In F/S mode, the repeated start operation can be disabled by clearing the PRCM.PRM_VC_I²C_CFG[4] SREN bit to 0.

17.5.3.3 HS I²C Configure the External Power Chip(s)

The LH can send configuration commands from one bypass input to the external power chip(s), using the same I²C interface. To send a configuration command, the LH must process as follows:

- Check whether the transmission of a configuration command is ongoing by polling the PRCM.PRM_VC_BYPASS_VAL[24] VALID bit (1: a transmission is ongoing, 0: a new transmission can start).
- Set the external power chip 7-bit slave address in the PRCM.PRM_VC_BYPASS_VAL[6:0] SLAVEADDR bit field, set the configuration register address of the external power chip in the PRCM.PRM_VC_BYPASS_VAL[15:8] REGADDR bit field, and set the data to be written to the external power chip configuration register in the PRCM.PRM_VC_BYPASS_VAL[23:16] DATA bit field.
- Set the PRCM.PRM_VC_BYPASS_VAL[24] VALID bit to 1 to send the configuration command to the external power chip.

17.6 HS I²C Register Manual

CAUTION

The HS I²C_i registers are limited to 16 bit and 8 bit data accesses; 32-bit data access is not allowed and can corrupt register content.

NOTE: For register configuration of HS I²C controller I2C4, see [Chapter 3, Power, Reset, and Clock Management](#).

[Table 17-15](#) provides the instance summary.

17.6.1 HS I²C Instance Summary

[Table 17-15](#) provides the instance summary.

Table 17-15. HS I²C Instance Summary

Module Name	Base Address	Size

This chapter describes the features and functions of the HDQ/1-Wire module.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
18.1 HDQ/1-Wire Overview	2864
18.2 HDQ/1-Wire Environment	2865
18.3 HDQ/1-Wire Integration	2868
18.4 HDQ/1-Wire Functional Description	2870

18.6 HDQ/1-Wire Use Cases and Tips	2880
18.7 HDQ/1-Wire Register Manual	2883

18.1 HDQ/1-Wire Overview

The HDQ/1-Wire module implements the hardware protocol of the master functions of the Benchmark HDQ and the Dallas Semiconductor 1-Wire® protocols. These protocols use a single wire for communication between the master (HDQ/1-Wire controller) and the slaves (HDQ/1-Wire external compliant devices).

Figure 18-1 shows the HDQ/1-Wire controller module.

Figure 18-1. HDQ/1-Wire Highlight

The HDQ and 1-Wire module has a generic L4 interface and is intended to be used in an interrupt-driven fashion. The one-pin interface is implemented as an open-drain output at the device level.

The HDQ operates from a fixed 12-MHz functional clock provided by the PRCM module.

Only the MPU subsystem uses the HDQ/1-Wire module.

The main features of the HDQ/1-Wire module support the following:

- Benchmark HDQ protocol
- Dallas Semiconductor 1-Wire protocol
- Power-down mode

The HDQ/1-Wire module provides a communication rate of 5K bits/s over an address space of 128 bytes.

A typical application of the HDQ/1-Wire module is the communication with battery monitor (gas gauge) integrated circuits.

18.2 HDQ/1-Wire Environment

18.2.1 HDQ/1-Wire Functional Interface

Figure 18-2 shows a typical application using the HDQ/1-Wire connection.

Figure 18-2. HDQ/1-Wire Typical Application System Overview

hdq1wr-002

An external pullup is required, because the two protocols use a return-to-1 mechanism (that is, logical '1' level is applied by a pullup after any drive-to-zero by a HDQ/1-Wire master or slave). Pullup is typically implemented as a resistor connected between HDQ/1-Wire line and the I/O power supply.

The HDQ/1-Wire module operates according to a command structure that is programmed into transmit command registers (as described in [Section 18.5](#)).

The 1-Wire mode runs at slower speeds than the capabilities of the mode.

[Table 18-1](#) describes the external signal for connection with HDQ or 1-Wire compliant devices.

Table 18-1. I/O Description

Signal Name	I/O	Description	Value at Reset
hdq_sio	Bidir	Serial data input/output. Output is open drain type.	0

18.2.2 HDQ and 1-Wire (SDQ) Protocols

18.2.2.1 HDQ Protocol Initialization (Default)

In HDQ mode, the firmware does not require the host to create an initialization pulse to the slave.

However, the slave can be reset by using an initialization pulse (also referred to as a break pulse). The initialization pulse is generated by setting the INITIALIZATION bit (HDQ.[HDQ_CTRL_STATUS](#)[2]). The slave does not respond with a presence pulse as it does in the 1-Wire protocol.

The HDQ is a command-based protocol in which the host sends a command byte to the slave. The command directs the slave either to store the next eight bits of data received to a register specified by the command byte (write operation) or to output the eight bits of data from a register specified by the command byte (read operation). The master implementation is a simple byte engine. The sending of the ID, command/address, and data is controlled by firmware. The master engine provides only a single HDQ.[HDQ_TX_DATA](#) register.

The command and data bytes consist of a stream of eight bits with a maximum transmission rate of 5K bits/s. The least significant bit (LSB) of a command or data byte is transmitted first. If a communication time-out occurs between the host and the slave (for example, if the host waits longer than the specified time for the slave to respond, or if this is the first access command), then the host must send an initialization pulse (BREAK pulse) before sending the command again.

The slave detects a break when the HDQ pin is driven to a logic-low state for a specified break time $t(B)$ or greater. The HDQ pin then returns to its normal ready-high logic state for a specified break-recovery time $t(BR)$. The slave is then ready for a command from the host processor. [Figure 18-3](#) shows this behavior.

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition. Reading the interrupt status register clears all interrupt conditions. Only one interrupt signal is sent to the microcontroller, and only one overall mask bit can enable or disable the interrupt. The interrupt conditions cannot be individually masked.

Figure 18-3. HDQ Break-Pulse Timing Diagram

18.2.2.2 1-Wire (SDQ) Protocol Initialization

In 1-Wire (SDQ) protocol, the host first sends an initialization pulse (by pulling the line to a logic-low state) and then waits for the slave to respond with a presence pulse before enabling any communication sequence.

As for the initialization pulse, the presence pulse is a low-going edge on the line initiated by the slave. The timing diagram in [Figure 18-4](#) shows the 1-Wire (SDQ) reset sequence.

Figure 18-4. 1-Wire (SDQ) Reset Timing Diagram

The host drives the line to a logic-low state for a minimum of reset low time. Once the slave detects this pulse, it must drive the line to a logic-low state within the presence pulse high delay for a minimum period of presence pulse low time.

If the slave does not respond within this interval of time, a time-out event occurs and no transaction can be initiated. The host must initiate the reset sequence again before sending any command to the slave.

On the other hand, if the slave sends back its presence pulse within the specified interval of time, the communication can be enabled after the reset high time.

18.2.2.3 Communication Sequence (HDQ and 1-Wire Protocols)

This section describes the part common to both protocols.

After a successful break pulse (HDQ mode) or initialization sequence (1-Wire protocol), the host and slave are ready for bit transmission. Each bit to transmit (either from the host to the slave or from the slave to the host) is preceded by a low-going edge on the line, as shown in [Figure 18-5](#).

Figure 18-5. HDQ/1-Wire Transmitted Bit Timing

hdq1wr-005

The return-to-1 data-bit frame consists of three distinct sections. The first section starts the transmission when either the slave or the host takes the line to a logic-low state. The next section is the actual data transmission in which the data must be valid during a specified period of time after the negative edge that starts the communication. The final section stops the transmission by returning the HDQ/1-Wire line to a logic-high state. Communication with an HDQ/1-Wire slave always occurs with the LSB being transmitted first.

The command byte of the HDQ/1-Wire protocols consists of eight contiguous valid command bits. The command byte contains two fields: R/W command and address. The R/W bit of the command byte determines whether the command is a read or a write, and the address field containing bits AD6-AD0 indicates the address to be read or written. [Table 18-2](#) lists the command byte values.

Table 18-2. HDQ/1-Wire Command Byte

7	6	5	4	3	2	1	0
R/W	AD6	AD5	AD4	AD3	AD2	AD1	AD0

- R/W** Indicates whether the command byte is a read or a write. A 1 indicates a write command; the following eight bits must be written to the register specified by the address field of the command byte. A 0 indicates that the command is a read. On a read command, the slave outputs the requested register contents.
- AD6-AD0** Represent the seven bits labeled AD6-AD0 containing the address portion of the register to be accessed.
The communication sequence example in [Figure 18-6](#) shows a read command at address 0x55; the received data is 0x65.

Figure 18-6. HDQ/1-Wire Communication Sequence

hdq1wr-006

18.3 HDQ/1-Wire Integration

Figure 18-7 shows the HDQ/1-Wire module integration in the device.

Figure 18-7. HDQ/1-Wire Integration

18.3.1 Clocking, Reset, and Power-Management Scheme

18.3.1.1 HDQ/1-Wire Clocks

There are two clock domains in the HDQ/1-Wire module: the functional clock domain and the interface clock domain. When these clocks are set in the PRCM module, the following rule must be observed: $\text{HDQ_ICLK} \geq \text{HDQ_FCLK}$.

- HDQ_FCLK belongs to the functional clock domain. It is a fixed 12-MHz clock provided by the PRCM. It is used to clock the internal module logic.

The HDQ_FCLK source is the CORE_12M_FCLK PRCM output, which is derived from the CORE_48M_FCLK clock signal (a 1/4 ratio is applied). The CORE_12M_FCLK clock is issued from the peripherals DPLL4. For more information about the clock, see [Chapter 3, Power, Reset, and Clock Management](#).

When the HDQ/1-Wire module no longer requires the HDQ_FCLK, the software can disable it at the PRCM level by setting the EN_HDQ bit (PRCM.CM_FCLKEN1_CORE[22]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it either.

For details about the PRCM register settings and DPLL4 configuration, see [Chapter 3, Power, Reset, and Clock Management](#).

- HDQ_ICLK is the interface clock. It runs at L4 interconnect clock speed and is used to trigger access to the HDQ/1-Wire L4 interface. Its source is the PRCM CORE_L4_ICLK signal. It typically runs at L3/2 frequency.

When the HDQ/1-Wire module no longer requires the HDQ_ICLK, the software can disable it at the PRCM level by setting the EN_HDQ bit (PRCM.CM_ICLKEN1_CORE[22]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it either.

It is also possible to activate an autoidle mode for this clock (AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] set to 1). In this case, HDQ_ICLK follows the CORE clock domain behavior. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

18.3.1.2 HDQ/1-Wire Reset Scheme

Global reset of the module is done either by activating the CORE_RST signal in the CORE_RST domain (for more information, see [Chapter 3, Power, Reset, and Clock Management](#)) or by setting to 1 the SOFTRESET bit HDQ.[HDQ_SYSCONFIG\[1\]](#). Setting this bit enables an active software reset functionality equivalent to a hardware reset.

18.3.1.3 HDQ/1-Wire Power Domain

The HDQ/1-Wire belongs to the CORE power domain. For more information about the CORE power domain, see [Chapter 3, Power, Reset, and Clock Management](#).

18.3.2 Hardware Requests

The HDQ/1-Wire can generate one interrupt:

- HDQ_IRQ: This is an interrupt to the MPU subsystem interrupt controller. It is mapped on M_IRQ_58.

18.4 HDQ/1-Wire Functional Description

The HDQ/1-Wire module works with both the HDQ and 1-Wire protocols. The protocols use a single wire to establish communication between the master and the slave. Both protocols use a return-to-1 mechanism; that is, after any command is driven, the line is pulled to a high level. This mechanism requires an external pullup.

18.4.1 HDQ/1-Wire Block Diagram

Figure 18-8 shows the HDQ/1-Wire block diagram.

Figure 18-8. HDQ/1-Wire Block Diagram

The MODE bit HDQ.HDQ_CTRL_STATUS[0] allows selection between the HDQ and 1-Wire protocols. This bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Figure 18-9 shows the protocol-dedicated register scheme.

Figure 18-9. Protocol Registers Description

hdq1wr-009

The receive and transmit operations are performed with respect to the HDQ protocol timing. The module is implemented once in the device and is clocked with a single clock whether it runs HDQ or 1-Wire protocol. Although the data exchange is slower than the capabilities of the 1-Wire mode, this mode still meets the timing requirements and practical considerations. That is, the 1-Wire protocol runs at the HDQ protocol speed, which is slower (5K bits/s). The timing parameters and protocol are different in the two modes.

18.4.2 HDQ Mode (Default)

18.4.2.1 HDQ Mode Features

The HDQ mode supports the following:

- Benchmark HDQ protocol
- Power-down mode

18.4.2.2 Description

In the HDQ mode, there is no need for the host to create an initialization pulse to the slave. However, the host can reset the slave by using an initialization pulse (also known as a break pulse). Setting the INITIALIZATION bit HDQ_CTRL_STATUS[2] creates this pulse by pulling the line down. When the slave receives the pulse, it is ready for communication but does not respond with a presence pulse.

In a typical write operation, two bytes are sent to the slave. The first byte corresponds to the command/address byte, and the second byte corresponds to the data to be written.

In a typical read operation, the host sends a command/address byte and the slave returns a byte of data.

The master is implemented to send and receive bytes. Sending the command/address and data is controlled by the firmware. The master provides only a single data TX register.

The HDQ protocol is a return-to-1 protocol. Consequently, after a byte is sent to the slave (either command/address + data for a write, or just command/address for a read), the host pulls the line up. The line is set to the high-impedance state in the device and an external pullup brings it to a logical high level.

In the case of a read operation, the slave also drives the line to a logic-low state before sending the requested data.

If the host initiates a read and does not receive data within a specified interval of time (that is, the slave does not drive the line low within this interval), the TIMEOUT bit HDQ.[HDQ_INT_STATUS\[0\]](#) is set, thereby indicating a read failure. The TIMEOUT bit remains set until the host reads the interrupt status register (HDQ.[HDQ_INT_STATUS](#)).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out on a transaction. The corresponding bit is set in the interrupt status register (HDQ.[HDQ_INT_STATUS](#)). This register is cleared as soon as it is read.

Only one interrupt signal is sent to the MPU, and only an overall mask can enable or disable the interrupts. These interrupts cannot be individually masked.

18.4.2.3 Single-Bit Mode

In HDQ mode, the single-bit mode (1_WIRE_SINGLE_BIT bit HDQ.[HDQ_CTRL_STATUS\[7\]](#) set to 1) has no effect because the HDQ protocol supports only byte transfers.

18.4.2.4 Interrupt Conditions

The HDQ/1-Wire module provides the following interrupt status:

1. Transmission complete:

A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in HDQ protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.[HDQ_INT_STATUS](#)).

2. Read complete:

In HDQ mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.[HDQ_INT_STATUS](#)).

3. Presence detect/time-out:

In HDQ mode, the interrupt status indicates that after a read command initiated by the host, the slave did not pull the line low within the specified time. This interrupt condition is cleared by reading the interrupt status register (HDQ.[HDQ_INT_STATUS](#)).

In HDQ mode, a time-out condition is also used to indicate the successful completion of a break pulse. That is, if the master has sent the break pulse, it is indicated with a time-out instead of a TX-complete.

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all the interrupt status bits that were previously set.

18.4.3 1-Wire Mode

18.4.3.1 1-Wire Mode Features

The 1-Wire mode supports the following:

- Dallas Semiconductor 1-Wire protocol
- Power-down mode
- Single-bit mode

18.4.3.2 Description

The 1-Wire mode requires an initialization pulse to be sent to the slave(s) connected on the interface. If a slave is present, it responds with a presence pulse.

The initialization pulse is sent after INITIALIZATION bit HDQ.[HDQ_CTRL_STATUS\[2\]](#) is set. The firmware sends the initialization pulse depending on the value of this bit.

The slave presence on the line is detected by a presence bit in the control and status register. When the slave receives the initialization pulse, it sends back its presence pulse by pulling down the line. The module detects this low-going edge and sets the PRESENCEDETECT bit HDQ.[HDQ_CTRL_STATUS\[3\]](#).

In a similar way, if a presence pulse is not received from the slave after an initialization pulse is sent, the PRESENCEDETECT bit remains cleared.

Whether or not a presence pulse is detected after an initialization pulse is sent, the TIMEOUT bit HDQ.[HDQ_INT_STATUS\[0\]](#) is set and an interrupt condition is generated.

In 1-Wire mode, the generated interrupt condition means the maximum time allowed for receiving the response has elapsed and the software must check the PRESENCEDETECT bit to determine whether or not there was a presence pulse.

The INITIALIZATION bit is cleared at the end of the initialization pulse at the same time as the TIMEOUT bit is set. The TIMEOUT bit is cleared when the interrupt status register (HDQ.[HDQ_INT_STATUS](#)) is read.

For read operations, 1-Wire is a bit-by-bit protocol, which means the slave must be clocked by the host for each bit of the byte to read.

The line is pulled up at the end of the command/address byte. On the first read, the host creates a low-going edge to initiate a bit read. The line is then pulled up (pulled to the high-impedance state by the host and set to a high logical level by the external pullup) and the slave either drives the line low to transmit a 0 or does not drive the line to transmit a 1. This sequence is repeated for each bit to read.

The first bit the host receives is the LSB, and the last bit is the most significant bit (MSB) in the receive data register (HDQ.[HDQ_RX_DATA](#)).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition (that is, the time allowed for the slave to indicate its presence has elapsed). A read operation on the interrupt status register clears the interrupt conditions previously set. As in the HDQ mode, only one interrupt signal is sent to the MPU. Only an overall mask bit can enable or disable the interrupt (the interrupt conditions cannot be masked individually).

18.4.3.3 1-Wire Single-Bit Mode Operation

A single-bit mode can be entered by setting the appropriate bit in the control and status register (1_WIRE_SINGLE_BIT bit HDQ.[HDQ_CTRL_STATUS\[7\]](#)). In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, an interrupt is generated (that is, there is an RX-complete for a read operation and a TX-complete for a write operation). Bit 0 of the RX register (HDQ.[HDQ_RX_DATA](#)) is updated each time a bit is received from the slave; bit 0 of the TX register (HDQ.[HDQ_TX_DATA](#)) contains the bit to be sent.

18.4.3.4 Interrupt Conditions

The HDQ/1-Wire module provides the following interrupt status:

1. Transmission complete:

A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in 1-Wire protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.[HDQ_INT_STATUS](#)).

2. Read complete:

In 1-Wire mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.[HDQ_INT_STATUS](#)).

3. Presence detect/time-out:

In 1-Wire mode, the interrupt status indicates that it is now valid to check the PRESENCEDETECT bit. This interrupt condition is cleared by reading the interrupt status register (HDQ.[HDQ_INT_STATUS](#)).

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all interrupt status bits that were previously set.

18.4.3.5 Status Flags

The presence-condition-detected status flag is contained in the PRESENCEDETECT bit HDQ.[HDQ_CTRL_STATUS](#)[3]. This is valid only in 1-Wire mode. The flag is updated when TIMEOUT bit HDQ.[HDQ_INT_STATUS](#)[0] is set. Therefore, its correct value shows only after the interrupt is generated. The firmware must wait for the time-out condition; otherwise, the flag keeps its previous value and is undefined.

18.4.4 Module Power Saving

18.4.4.1 Autoidle Mode

The HDQ/1-Wire module provides an autoidle function in its interconnect clock domain.

The interconnect clock autoidle power-saving mode is enabled or disabled through the AUTOIDLE bit HDQ.[HDQ_SYSCONFIG](#)[0]. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock (HDQ_ICLK) is disabled inside the module, thereby reducing power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted with no latency penalty. This mode is disabled by default after a reset.

This mode is recommended to reduce power consumption.

18.4.4.2 Power-Down Mode

The HDQ/1-Wire module also provides a power-saving function in its functional clock domain.

Setting the CLOCKENABLE bit in the control and status register (CLOCKENABLE bit HDQ.[HDQ_CTRL_STATUS](#)[5]) to 0 shuts off the functional clock (HDQ_FCLK) to the state-machine. The state-machine is reset when the functional clock is disabled; if any transaction is ongoing, it is aborted into the reset state.

The register values are not affected by disabling the functional clock.

Do not access the module registers after the software has put the module in power-down mode except to write to the CLOCKENABLE bit to take the module out of power-down mode.

18.4.5 System Power Management and Wakeup

As part of the system-wide power-management scheme, the HDQ/1-Wire module can go into idle state at the request of the PRCM module (for more information, see [Chapter 3, Power, Reset, and Clock Management](#)). However, the HDQ/1-Wire module does not support handshake protocol with the PRCM. The HDQ/1-Wire module can go into idle mode only as part of the L4 interconnect clock domain (both CORE_L4_ICLK and FUNC_12M_CLK belong to the L4 interconnect clock domain).

When the AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] is set, the HDQ/1-Wire module behavior follows the L4 interconnect clock domain behavior. If the whole domain is put into idle, the HDQ/1-Wire is also put into idle.

Software must ensure correct clock management.

CAUTION

There is no hardware mechanism to prevent cutting off the HDQ/1-Wire clocks while the module is performing a transfer. The result would be a loss of data being transferred.

18.5 HDQ/1-Wire Basic Programming Model

The HDQ/1-Wire module can be considered a simple byte engine because it only implements the hardware interface layer for both HDQ and 1-Wire protocols. The correct sequencing is controlled by the firmware, which is described in this section.

18.5.1 Module Initialization Sequence

18.5.1.1 Mode Selection

MODE bit HDQ.[HDQ_CTRL_STATUS\[0\]](#) allows selection between the HDQ and 1-Wire protocols. When set to 0, the protocol is HDQ; when set to 1, the protocol is 1-Wire. The bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Although this bit can be modified at any point, it is strongly recommended that it be modified only as part of the boot-up configuration.

18.5.1.2 Reset/Initialization

No slave presence test is required in HDQ mode; however, the slave can be reset by setting the INITIALIZATION bit HDQ.[HDQ_CTRL_STATUS\[2\]](#) and the GO bit HDQ.[HDQ_CTRL_STATUS\[4\]](#). The line is then pulled down (break pulse) and the bit returns to 0 after the pulse is sent. Upon completion, a time-out interrupt is also generated. The slave does not respond to this pulse.

In 1-Wire mode, the slave returns a presence pulse when it receives the initialization pulse. The protocol for initialization is as follows:

1. Set the INITIALIZATION bit HDQ.[HDQ_CTRL_STATUS\[2\]](#) to 1 and the GO bit HDQ.[HDQ_CTRL_STATUS\[4\]](#) to 1 to send the pulse. When the pulse is sent, the bit is cleared in the register.
2. Wait for the presence detect flag (TIMEOUT bit HDQ.[HDQ_INT_STATUS\[0\]](#)) to generate an interrupt. This flag is set when the response time allowed to the slave has elapsed, whether it has sent a pulse or not.
3. Read the HDQ.[HDQ_CTRL_STATUS](#) register to check whether the presence pulse has been received before starting any transfer.

18.5.2 HDQ Protocol Basic Programming Model

18.5.2.1 Write Operation

The write operation sequence is as follows:

1. Write the command/address or data value to the TX write register (HDQ.[HDQ_TX_DATA](#)).

NOTE: Steps 2 and 3 can be performed simultaneously.

2. Set DIR bit HDQ.[HDQ_CTRL_STATUS\[1\]](#) to indicate a write.
3. Set GO bit HDQ.[HDQ_CTRL_STATUS\[4\]](#) to start the transmission.
 - (a) The hardware sends the byte from the TX write register.
 - (b) In a write operation, the TIMEOUT bit is always cleared, because there is no acknowledge mechanism from the slave.
 - (c) When the write operation is completed, the TX-complete flag is set in the interrupt status register (TXCOMPLETE bit HDQ.[HDQ_INT_STATUS\[2\]](#)). If interrupts are masked (that is, the corresponding bit has been previously set in the control and status register), no interrupt signal is generated.
 - (d) The GO bit HDQ.[HDQ_CTRL_STATUS\[4\]](#) is cleared at the end of a write operation.
4. The software must read the interrupt status register to clear the interrupt.
5. Repeat step 1 through step 4 for each successive byte to write.

18.5.2.2 Read Operation

The read operation sequence is as follows:

1. Write the command value to the TX write register (HDQ.[HDQ_TX_DATA](#)).
2. Set DIR bit HDQ.[HDQ_CTRL_STATUS](#)[1] to 0 and GO bit HDQ.[HDQ_CTRL_STATUS](#)[4] to 1 and wait for the TX-complete interrupt.

NOTE: Steps 3 and 4 can be performed simultaneously.

3. Set DIR bit HDQ.[HDQ_CTRL_STATUS](#)[1] to 1 to indicate a read.
4. Write 1 to GO bit HDQ.[HDQ_CTRL_STATUS](#)[4] to initiate the read.
 - (a) The hardware detects a low-going edge on the line (generated by the slave) and receives 8 bits of data in the RX receive buffer register (HDQ.[HDQ_RX_DATA](#)). The first bit received is the LSB and the last bit is the MSB. The master performs this step as soon as the slave sends the data, irrespective of the state of GO bit HDQ.[HDQ_CTRL_STATUS](#)[4]. However, an RX-complete interrupt is generated only when the software writes the GO bit.
 - (b) If a time-out occurs, the TIMEOUT bit HDQ.[HDQ_CTRL_STATUS](#)[0] is set.
 - (c) Completion of the operation is indicated by setting the RX-complete flag in the interrupt status register (TXCOMPLETE bit HDQ.[HDQ_INT_STATUS](#)[1]). If interrupts are masked (that is, the corresponding bit was previously set in the control and status register), no interrupt signal is generated.
 - (d) At the end of the read operation, the GO bit HDQ.[HDQ_CTRL_STATUS](#)[4] is cleared. It is also cleared if a time-out is detected
5. The software must read the interrupt status register (HDQ.[HDQ_INT_STATUS](#)) to determine whether an RX was successfully completed or a time-out occurred.
6. The software reads the RX receive buffer register (HDQ.[HDQ_RX_DATA](#)) to retrieve the read data from the slave.
7. Repeat step 1 through step 6 for each successive byte.

NOTE: In HDQ mode, the address/command is written only once to the slave. However, after the first byte is received, an RX-complete interrupt is set. Therefore, the software must initiate the read of the second byte by setting the GO bit in the control and status register. The first byte received is shadowed and provided to the software while the hardware is fetching the second byte of data.

18.5.3 1-Wire Mode (SDQ) Basic Programming Model

18.5.3.1 Write Operation

The write operation sequence is as follows:

1. Write the ID, command, or data value to the TX write register (HDQ.[HDQ_TX_DATA](#)).

NOTE: Steps 2 and 3 can be performed simultaneously.

2. Set DIR bit HDQ.[HDQ_CTRL_STATUS](#)[1] to 0 to indicate a write operation.
3. Set GO bit HDQ.[HDQ_CTRL_STATUS](#)[4] to 1 to start the transmission.
 - (a) The hardware sends the byte stored in the TX write register.
 - (b) In a write operation, the TIMEOUT bit is always cleared.
 - (c) When the operation is completed, the TX-complete flag is set in the interrupt status register (TXCOMPLETE bit [HDQ_INT_STATUS](#) [2]). No interrupt signal is generated if interrupts are masked (that is, the corresponding bit was previously set in the control and status register).
 - (d) The GO bit of the control and status register is cleared at the end of a write operation.

4. The software must read the interrupt status register (HDQ.HDQ_INT_STATUS) to clear the interrupt.
5. Repeat step 1 through step 4 for each successive byte to write.

18.5.3.2 Read Operation

The read operation sequence is as follows:

1. Write the address to the TX write register (HDQ.HDQ_TX_DATA).
2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 and the GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 and wait for the TX-complete interrupt flag.
3. Write the command value to the TX write register (HDQ.HDQ_TX_DATA).
4. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 and GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 and wait for the TX-complete interrupt flag.

NOTE: Steps 5 and 6 can be performed simultaneously.

5. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 1 to indicate a read.
6. Set GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 to start the transmission.
 - (a) The hardware (master) generates a low-going edge and clocks 8 bits of data into the RX receive register (HDQ.HDQ_RX_DATA). The first bit received is the LSB and the last bit is the MSB.
 - (b) TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is always cleared in a read operation.
 - (c) When the operation is complete, the RX-complete flag is set in the interrupt status register (RXCOMPLETE bit HDQ.HDQ_INT_STATUS[1]). No interrupt signal is generated if the interrupts are masked (that is, the corresponding bit was previously set in the control and status register).
 - (d) GO bit HDQ.HDQ_CTRL_STATUS[4] is cleared at the end of the read. It is also cleared if a time-out occurs.
7. The software must read the interrupt status register to determine whether an RX was successfully completed or a time-out occurred.
8. The software reads the RX receive buffer register (HDQ.HDQ_RX_DATA) to retrieve the read data from the slave.
9. Repeat step 1 through step 8 for each successive byte.

18.5.3.3 1-Wire Bit Mode Operation

Select the single-bit mode by setting the 1_WIRE_SINGLE_BIT bit HDQ.HDQ_CTRL_STATUS[7] to 1. In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, the corresponding interrupt flag is set (that is, there is an RX-complete (RXCOMPLETE bit HDQ.HDQ_INT_STATUS[1]) for a read operation and a TX-complete (TXCOMPLETE bit HDQ.HDQ_INT_STATUS[2]) for a write operation). Bit 0 of the RX register (HDQ.HDQ_RX_DATA) is updated each time a bit is received; bit 0 of the TX register (HDQ.HDQ_TX_DATA) contains the bit of data to be sent.

18.5.4 Power Management

The software has independent control of the two clock domains (interconnect clock: HDQ_ICLK and functional clock: HDQ_FCLK). Because there is no acknowledge mechanism from the HDQ/1-Wire module to an idle request, the software must ensure that a clock is not shut off while a transfer is being processed (the data would be lost).

If the autoidle function (AUTOIDLE bit HDQ.HDQ_SYSCONFIG[0] set to 1) provides a safe transfer (the module wakes up the HDQ_ICLK as soon as a transfer is initiated), the power-down mode and the PRCM idle requests (through the whole L4 clock domain idle request) must be handled carefully.

The following sections describe the steps to follow to use the power-down and idle modes.

18.5.4.1 Module Power-Down Mode

1. Before shutting off the HDQ_FCLK, wait for an RX-complete or a TX-complete interrupt.

- In a read operation, the transfer is completed when the RX-complete flag (RXCOMPLETE bit HDQ.[HDQ_INT_STATUS](#) [1]) generates an interrupt.
- In a write operation, the transfer is completed when the TX-complete flag (TXCOMPLETE bit HDQ.[HDQ_INT_STATUS](#) [2]) generates an interrupt. The software must check whether the interrupt was generated after the address/command byte was sent or after the data byte was sent. The clock must not be shut off after the command/address byte is sent; otherwise, the data is not written to the slave.

HDQ.[HDQ_INT_STATUS](#) must be read to clear the interrupt condition.

2. Set the CLOCKENABLE bit HDQ.[HDQ_CTRL_STATUS](#)[5] to 0 to disable the clock.

Do not access the module registers after the software has put the module into power-down mode except to write to the clock-enable bit to take the module out of power-down mode.

18.5.4.2 System Idle Mode

This section describes the steps to follow at the module level before enabling the idle mode at the system level (for more information about the system power management scheme, see [Chapter 3, Power, Reset, and Clock Management](#)).

As part of the L4 interconnect clock domain, the HDQ/1-Wire clocks can be cut at the PRCM level. HDQ_FCLK can be cut if the EN_HDQ bit PRCM.CM_FCLKEN1_CORE [22] is set to 0 and no other modules require CORE_12M_FCLK. The software must verify that no transfer is in progress.

In a read operation:

1. Wait for an RX-complete interrupt.

In a read operation, the transfer is completed when the RX-complete flag (RXCOMPLETE bit HDQ.[HDQ_INT_STATUS](#) [1]) generates an interrupt.

2. Read the HDQ.[HDQ_INT_STATUS](#) to clear the read-complete interrupt flag.
3. Read the HDQ.[HDQ_RX_DATA](#) to retrieve the read data.
4. The HDQ_ICLK can be shut off by entering the system idle mode.

In a write operation:

1. Wait for a TX-complete interrupt.

In a write operation, the transfer is completed when the TX-complete flag (TXCOMPLETE bit HDQ.[HDQ_INT_STATUS](#)[2]) generates an interrupt. The software must check whether the interrupt was generated after the address/command byte was sent or after the data byte was sent. The clock must not be shut off after the command/address byte is sent; otherwise, the data is not written to the slave.

2. Read the HDQ.[HDQ_INT_STATUS](#) to clear the TX-complete interrupt flag.
3. The HDQ_ICLK can be shut off by entering the system idle mode.

Concerning HDQ_ICLK, two situations can occur:

- The clock is no longer required and EN_HDQ bit PRCM.CM_ICLKEN1_CORE[22] is set by software. In this case, the clock is cut off, provided no other modules require it. Before setting the EN_HDQ bit, the software must follow the steps described in this section.
- AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] is set. In this case, the software must verify that all HDQ/1-Wire transfers are complete before enabling the L4 interconnect clock domain idle mode. Otherwise, the HDQ/1-Wire has no way to prevent the clock from being cut, because no hardware mechanism exists. The steps listed in this section must be verified before putting the L4 clock domain into idle state.

18.6 HDQ/1-Wire Use Cases and Tips

18.6.1 How to Configure the HDQ/1-Wire when Connected with a BQ27000 Gauge

18.6.1.1 Environment

Figure 18-10 details the device connections with the BQ27000 gauge.

Figure 18-10. Environment

18.6.1.2 Programming Flow

This section details the programming flow of the HDQ/1-Wire. Figure 18-11 shows the main steps of this configuration. The BQ27000 gauge uses the HDQ mode.

Figure 18-11. HDQ/1-Wire Configuration in HDQ Mode

18.6.1.3 Pad Configuration and HDQ/1-Wire Clock and Power Management

Table 18-3 shows the pad multiplexing and the clock and power management configuration to select for the HDQ/1-Wire module.

Table 18-3. Registers Print for HDQ/1-Wire Configuration

Register Name	Address	Value	Value description
SCM.CONTROL_PA DCONF_I2C3_SDA	0x 4800 21C4	0x0118 0100	Configure hdq_sio pad in mode 0

Table 18-3. Registers Print for HDQ/1-Wire Configuration (continued)

Register Name	Address	Value	Value description
PRCM.CM_FCLKEN_1_CORE	0x4800 4A00	0x0020 0000	Enable HDQ/1-Wire Functional clock
PRCM.CM_ICLKEN_1_CORE	0x4800 4A10	0x0020 0000	Enable HDQ/1-Wire Interface clock
HDQ_CTRL_STATUS	0x480B 200C	0x0000 0020	Enable clocks and select the HDQ mode
HDQ_SYSCONFIG	0x480B 2014	0x0000 0000	Module clock is free-running (Disable autoidle mode)

18.6.1.4 HDQ/1-Wire Software Reset

Perform a software reset as described in [Figure 18-12](#).

Figure 18-12. Software Reset Flowchart

hdq1wr-013

[Table 18-4](#) describes the registers to be configured for the HDQ/1-Wire software reset step.

Table 18-4. Registers Print for HDQ/1-Wire Software Reset

Register Name	Address	Value	Value description
HDQ_SYSCONFIG	0x480B 2014	0x0000 0002	Initiate a software reset. The HDQ_SYSCONFIG[1] SOFTRESET is automatically reset by hardware.
HDQ_SYSSTATUS	0x480B 2018	0x0000 0001	The HDQ_SYSSTATUS[0] RESETDONE is set to 1 when the reset sequence is done.

18.6.1.5 Interrupts Enable

[Table 18-5](#) describes the registers to be configured for the interrupts enable step and the use case values.

Table 18-5. Registers Print for HDQ/1-Wire Interrupts Enable

Register Name	Address	Value	Value description
HDQ_CTRL_STATUS	0x480B 200C	0x0000 0060	Enable Interrupts

18.6.1.6 Read and Write Operations

The Read and Write operations in HDQ mode are described in [Section 18.5.2](#).

Some write operations are needed to configure the BQ27000 gauge: for example, it is necessary to write a COMMAND KEY (0xA9 or 0x56) in the Device Control Register of the gauge. For more information, see the TI BQ27000 gauge specification.

18.7 HDQ/1-Wire Register Manual

18.7.1 HDQ/1-Wire Instance Summary

Table 18-6 lists the HDQ/1-Wire instances.

Table 18-6. Instance Summary

Module Name	Base Address	Size
HDQ/1-Wire	0x480B 2000	4K bytes

CAUTION

All reserved bits must be written with 0. There is no synchronization between the register clock domain and the state-machine domain. Therefore, the following rules must be observed when accessing the module registers:

- A read from the interrupt status register or the receive buffer register is not allowed unless the processor has been interrupted by the module.
- After the release of the GO bit in the control and status register, no access to the TX data register or the control and status register is allowed until the processor has been interrupted by the module.
- Polling of the interrupt status register by software to determine whether an interrupt was generated is not allowed.
- No access to the module registers should be done after the software puts the module in power-down mode (by setting bit 5 of the control and status register to 0) except to re-enable the clock.

CAUTION

The HDQ/1-Wire registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

18.7.2 HDQ/1-Wire Register Mapping Summary

Table 18-7 lists the HDQ/1-Wire registers.

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
19.1 UART/IrDA/CIR Overview	2892
19.2 UART/IrDA/CIR Environment	2895
19.3 UART/IrDA/CIR Integration	2908
19.4 UART/IrDA/CIR Functional Description	2912
19.5 UART/IrDA/CIR Basic Programming Model	2942
19.6 UART/IrDA/CIR Register Manual	2950

19.1 UART/IrDA/CIR Overview

The device contains three universal asynchronous receiver/transmitter (UART) devices controlled by the microprocessor unit (MPU) (see Figure 19-1):

- Three UART-only modules, UART1, UART2 and UART4 are pinned out for use as UART devices only. UART1 and UART2 must be programmed by setting the `UARTi.MDR1_REG[2:0]` MODE_SELECT field to one of the three UART operating modes.
- UART3, which adds infrared communication support, is pinned out for use as a UART, infrared data association (IrDA), or consumer infrared (CIR) device, and can be programmed to any available operating mode.

Figure 19-1. UART Module

19.1.1 UART Features

The UARTs (UART1, UART2, UART3, UART4 when in UART mode) include the following key features:

- 16C750 compatibility
- 64-byte FIFO for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable divisors N ($N = 1 \dots 16,384$) operating from a fixed functional clock of 48 MHz

Oversampling is programmed by software as 16 or 13; thus, the baud rate computation is either:

- Baud rate = (functional clock/16)/N
- Baud rate = (functional clock/13)/N

This software programming mode enables higher baud rates with the same error amount without changing the clock source:

- Break character detection and generation
- Configurable data format
 - Data bit: 5, 6, 7, or 8 bits
 - Parity bit: Even, odd, none
 - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF) (UART1, UART2 and UART3 only)

The UART clocks are connected to produce a baud rate of up to 3.6M bits/s. [Table 19-1](#) lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

Table 19-1. UART Mode Baud Rates, Divisor Values, and Error Rates

Baud Rate	Oversampling	Divisor	Error (%)
300	16	10000	0
600	16	5000	0
1200	16	2500	0
2400	16	1250	0
4800	16	625	0
9600	16	312	0.16
14,400	16	208	0.16
19,200	16	156	0.16
28,800	16	704	0.16
38,400	16	78	0.16
57,600	16	52	0.16
115,200	16	26	0.16
230,400	16	13	0.16
460,800	13	8	0.16
921,600	13	4	0.16
1,843,200	13	2	0.16
3,000,000	16	1	0
3,686,400	13	1	0.16

19.1.2 IrDA Features

The IrDA (UART3 only) includes the following key features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications
 - Frame formatting: Addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
 - Uplink/downlink cyclic redundancy check (CRC) generation/detection
 - Asynchronous transparency (automatic insertion of break character)
 - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
 - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection

[Table 19-2](#) lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

Table 19-2. UART IrDA Mode Baud Rates, Divisor Values, and Error Rates

Baud Rate	IR Mode	Encoding	Divisor	Error (%)
2400	SIR	3/16	1250	0
9600	SIR	3/16	312	0.16
19,200	SIR	3/16	156	0.16
38,400	SIR	3/16	78	0.16
57,600	SIR	3/16	52	0.16
115,200	SIR	3/16	26	0.16
576,000	MIR	1/4	2	0
1,152,000	MIR	1/4	1	0
4,000,000	FIR	4 PPM ⁽¹⁾	1	0

⁽¹⁾ PPM = pulse-position-modulation

NOTE: The maximum baud rate required of the module does not depend on the change of OPP.

19.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable t period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR (UART3 only) includes the following key features to provide CIR support for remote control applications:

- Transmit mode only (receive mode is not supported)
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

19.2 UART/IrDA/CIR Environment

This section describes the UART/IrDA/CIR connection with an external device.

19.2.1 System Using UART Communication with Hardware Handshake

UART1, UART2, UART3 or UART4 can be connected easily to the UART port of an external IC (see Figure 19-2).

Figure 19-2. UART Mode Bus System Overview

NOTE: UART4 does not provide flow control, so it does not have uarti_rts and uarti_cts signals

19.2.2 System Using IrDA Communication Protocol

As Figure 19-3 shows, UART3 can be connected to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

Figure 19-3. IrDA System Overview

19.2.3 System Using CIR Communication Protocol with Remote Control

UART3 can be connected to an external Infrared transceiver in CIR mode (see Figure 19-4).

Figure 19-4. CIR System Overview

19.2.4 UART Interface Description

19.2.4.1 UART Interface Description

Table 19-3 describes the UART interface.

Table 19-3. UART I/O Pin Description

Signal	I/O ⁽¹⁾	Description	Reset
UART Modem Signals			
uarti_rx	I	Serial data input	Unknown
uarti_tx	O	Serial data output	1
uarti_cts	I	Clear to send (UART1, UART2 and UART3 only)	Unknown
		Active-low modem status signal. Reading the <code>UARTi.MSR_REG[4]</code> NCTS_STS bit checks the condition of <code>uarti_cts</code> . Reading the <code>UARTi.MSR_REG[0]</code> CTS_STS bit checks a change of state of <code>uarti_cts</code> since the last read of the modem status register. The auto-nCTS mode uses <code>uarti_cts</code> to control the transmitter.	
uarti_rts	O	Request to send (UART1, UART2 and UART3 only) When active (low), the module is ready to receive data. Setting the <code>UARTi.MCR_REG[1]</code> RTS bit activates <code>uarti_rts</code> , which becomes inactive as the result of a module reset, loopback mode, or clearing the <code>UARTi.MCR_REG[1]</code> RTS bit. In auto-RTS mode, <code>uarti_rts</code> becomes inactive as a result of the receiver threshold logic.	1

⁽¹⁾ I = Input, O = Output

19.2.4.2 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x mode ($\leq 230.4\text{K}$ bits/s)
- UART 16x mode with autobauding (≤ 1200 bits/s and $\leq 115.2\text{K}$ bits/s)
- UART 13x mode ($\geq 460.8\text{K}$ bits/s)

CAUTION

To be used as a UART, the operating mode must be programmed appropriately in the `UARTi.MDR1_REG[2:0]` MODE_SELECT field to select the UART, IrDA, or CIR mode.

The UART uses a wired interface for serial communication with a remote device.

The UART module is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 19-5 shows the UART frame data format.

Figure 19-5. UART Frame Data Format

uart-005

19.2.5 IrDA Functional Interfaces

19.2.5.1 UART3 Interface Description

Table 19-4 describes the UART3 interface.

Table 19-4. UART3 I/O Description

Signal	I/O ⁽¹⁾	Description	Reset
IrDA Signals			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_tx_irtx	O	Serial data output in IrDA modes (SIR, MIR, and FIR). In other modes, this pin is set to the reset value (inactive state).	0 ⁽²⁾
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.ACREG_REG[6] SD_MOD bit.	1

⁽¹⁾ I = Input, O = Output

⁽²⁾ This value is only for IrDA mode. It is not for UART and CIR modes.

19.2.5.2 IrDA Protocol and Data Format

19.2.5.2.1 SIR Mode

In SIR mode, data is transferred between the MPU and peripheral devices at speeds of up to 115,200 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), is followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start bit, 8 data bits, and 1 stop bit, and is unaffected by the use and settings of the UART3.LCR_REG register.

The UART3.BLR_REG[6] XBOF_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine first sends an escape character (0x7D), then inverts the fifth bit of the real data to be sent, and sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors, such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, and a frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR_REG) to find possible errors of the received frame.

NOTE: Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the UART3.ACREG_REG[5] DIS_IR_RX bit description. This applies to all three modes: SIR, MIR, and FIR.

Infrared output in SIR mode can be either 1.6- μ s or 3/16th encoding, selected by the UART3.ACREG_REG[7] PULSE_TYPE bit. In 1.6- μ s encoding, the infrared pulse width is 1.6 μ s; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/baud rate).

The transmitting device must send at least two start flags at the start of each frame for back-to-back frames.

NOTE: Reception supports variable-length stop-bits.

19.2.5.2.1.1 Frame Format

Figure 19-6 shows the IrDA SIR frame format.

Figure 19-6. IrDA SIR Frame Format

The CRC is applied on the address (A), control (C), and information (I) bytes.

NOTE: The two words of CRC are written to the FIFO in reception.

19.2.5.2.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:
 - Inserts a control escape (CE) byte preceding the byte
 - Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)

The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).
- In reception:
 - For the A, C, I, CRC field:

- Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO
- If the byte is equal to the CE byte, discards the CE byte
- Complements bit 5 of the byte following the CE
- Sends the complemented byte to the CRC detector and stores it in the RX FIFO

19.2.5.2.1.3 Abort Sequence

The transmitter can decide to prematurely close a frame. The transmitter aborts by sending the following sequence: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

The receiver treats a frame as an aborted frame when a 0x7D character followed immediately by a 0xC1 character is received without transparency.

19.2.5.2.1.4 Pulse Shaping

The SIR mode supports both the 3/16th and the 1.6- μ s pulse duration methods in receive and transmit. The UART3.ACREG_REG[7] PULSE_TYPE bit selects the pulse width method in transmit mode.

19.2.5.2.1.5 Encoder

Serial data from the transmit state-machine is encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the uart3_tx_irtx line is always low, and the counter used to form a pulse on uart3_tx_irtx is cleared continuously.

After the TX FIFO output resets to 0, uart3_tx_irtx rises on the falling edge of the 7th 16XCLK. On the falling edge of the 10th 16XCLK pulse, uart3_tx_irtx falls, creating a three-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the 7th to the 10th clock of each 16-clock bit cycle.

Figure 19-7 shows the IrDA SIR encoding mechanism.

Figure 19-7. IrDA SIR Encoding Mechanism

uart-007

19.2.5.2.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 19-8 shows the IrDA SIR decoding mechanism.

Figure 19-8. IrDA SIR Decoding Mechanism

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the uart3_rx_irrx input can be disabled using the **UART3.ACREG_REG[5]** DIS_IR_RX bit. Furthermore, the **UART3.MDR2_REG[6]** IRRXINVERT bit can invert the signal from the transceiver (RXD) pin to the IRRX logic inside the UART. This inversion is performed by default.

19.2.5.2.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting **EFR_REG[1:0]** (see [Table 19-5](#)), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UART3 receives in IrDA mode, use the **UART3.XON1_ADDR1_REG[7:0]** field and the **UART3.XON2_ADDR2_REG[7:0]** field.

Table 19-5. EFR_REG[0-1] IR Address Checking Options

EFR_REG[1]	EFR_REG[0]	IR Address Checking
0	0	All address-checking operations disabled
0	1	Only address 1 checking enabled
1	0	Only address 2 checking enabled
1	1	All address-checking operations enabled

19.2.5.2.2 SIR Free Format Mode

To allow complete software flexibility when transmitting and receiving infrared data packets, the SIR free format (FF) mode is a subfunction of the existing SIR mode; all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

This mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

[Figure 19-9](#) shows the SIR free format mode.

Figure 19-9. SIR Free Format Mode

In the SIR free format mode, the MPU software must construct (that is, encode and decode) the entire FIFO data packet.

19.2.5.2.3 MIR Mode

In MIR mode, data is transferred between the MPU and the peripheral devices at 0.576 or 1.152M bits/s speed. A MIR transmit frame starts with start flags (at least two), followed by a frame data, CRC-16, and ends with a stop flag (see [Figure 19-10](#)).

Figure 19-10. MIR Transmit Frame Format

On transmit, the MIR state-machine attaches start flags, CRC-16, and stop flags, as in SIR mode. All fields are transmitted least-significant bit (LSB) of each byte first.

Contrary to SIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for both start and stop flags (unambiguously, not data, because of bit-stuffing).
- Abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit stuffing).
- Back-to-back frames are allowed with three or more stop flags in between. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors, such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.[LSR_REG](#)) to detect possible errors of the received frame.

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

19.2.5.2.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of +/-0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by the IrDA specifications.

Figure 19-11 shows the MIR baud rate adjustment mechanism.

Figure 19-11. MIR Baud Rate Adjustment Mechanism

19.2.5.2.3.2 SIP Generation

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is currently occupied.

Figure 19-12 shows the SIP.

Figure 19-12. SIP

19.2.5.2.4 FIR Mode

In FIR mode, data is transferred between the MPU and the peripheral devices at 4M bits/s. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Table 19-6 shows the FIR transmit frame format.

Table 19-6. FIR Transmit Frame Format

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag
-------------------	------------	------------	--------	-----------

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see [Table 19-7](#)) and generates the SIP (see [Section 19.2.5.2.3.2, SIP Generation](#)).

Table 19-7. 4-PPM Format

Data Bit Pair (Bin)	4-PPM Data Symbol (Bin)
00	1000
01	0100
10	0010
11	0001

The four symbols described in [Table 19-7](#) are the legal encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see [Table 19-8](#)).

Table 19-8. FIR Preamble, Start Flag, and Stop Flag

Frame Part	Transmitted Frame (Bin)
Preamble	1000 0000 1010 1000 (16 repeated transmissions)
Start Flag	0000 1100 0000 1100 0110 0000 0110 0000
Stop Flag	0000 1100 0000 1100 0000 0110 0000 0110

All fields are transmitted the LSBs of each byte first (see [Table 19-9](#)).

Table 19-9. FIR Data Byte Transmission Order Example

Data Byte (Hex)	Data Byte Pair (Bin)	4-PPM Data Symbol (Bin)	Transmission Order
0xB	00	1000	4
	00	1000	3
	10	0010	2
	11	0001	1

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors, such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.[LSR_REG](#)) to detect possible errors of the received frame.

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

19.2.6 CIR Functional Interfaces

19.2.6.1 CIR Interface Description

Table 19-10 describes the CIR interface.

Table 19-10. CIR I/O Description

Signal	I/O ⁽¹⁾	Description	Reset
CIR Signals			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_cts_rctx	O	Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.ACREG_REG[6] SD_MOD bit.	1

⁽¹⁾ I = Input, O = Output

19.2.6.2 CIR Protocol and Data Format

In the CIR mode, the infrared operation functions as a programmable (universal) remote control.

The CIR mode uses a variable PWM technique (based on multiples of a programmable t period) to encompass the various formats of infrared encoding for remote control applications. The CIR logic transmits data packets based on the user-defined frame structure and packet content.

19.2.6.2.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see Figure 19-13).

Figure 19-13. CIR Pulse Modulation

uart-014

19.2.6.2.2 Pulse Duty Cycle

The programmer can choose between four possible duty cycles for modulation pulses by setting the appropriate value in the UART3.MDR2_REG[5:4] CIR_PULSE_MODE field (1/4, 1/3, 5/12, or 1/2).

Figure 19-14 shows the CIR modulation duty cycles.

Figure 19-14. CIR Modulation Duty Cycle

The transmission logic ensures that all pulses are transmitted completely (that is, no cutoff during transmission). Furthermore, while transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end needs it.

19.2.6.2.3 Consumer IR Encoding/Decoding

There are two methods of encoding for remote control applications. The first method uses time-extended bit forms (a variable pulse distance, or duration, in which the difference between a logic 1 and logic 0 is the length of the pulse width).

The second encoding method uses a biphase in which the encoding of the logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively. Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphase encoding.

The CIR mode uses a completely flexible free-format encoding in which the TX FIFO is transmitted as a modulated pulse with duration T.

Similarly, 0 is transmitted as a blank duration T. The MPU constructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see Figure 19-15.).

Figure 19-15. RC-5 Bit Encoding

Because the CIR mode logic does not impose a fixed format for infrared packets of data, the MPU software can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the MPU software must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (that is, multiples of T) is the method used to distinguish between 1 and 0. The following SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

[Figure 19-16](#) shows SIRC bit encoding.

Figure 19-16. SIRC Bit Encoding

To construct comprehensive packets constituting remote-control commands, the MPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

[Figure 19-17](#) shows a standard RC-5 frame as detected by the UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two T pulses (digital bits) from the TX and RX FIFOs.

Figure 19-17. RC-5 Standard Packet Format

S1	S2	T	A4	A3	A2	A1	A0	C5	C4	C3	C2	C1	C0
----	----	---	----	----	----	----	----	----	----	----	----	----	----

uart-018

Where:

- S1, S2: Start bits (always 1)
- T: Toggle bit
- A4..A0: Address (or system) bits
- C5..C0: Command bits

The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the MPU transmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that allows the command range to increase to 7 bits. This format is known as the extended RC-5 format.

SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits inside the standard frame length varies.

[Figure 19-18](#) shows the packet format and bit encoding. As [Figure 19-19](#) shows, 1 start bit of 2 ms and control codes are followed by data that constitute the entire frame.

Figure 19-18. SIRC Packet Format

S	C0	C1	C2	C3	C4	C5	C6	D0	D1	D2	D3	D4
---	----	----	----	----	----	----	----	----	----	----	----	----

uart-019

NOTE: The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for emitting and receiving data packets must exercise a scheme of interpacket delay, where the emission of successive packets can be done only after a real-time delay has expired.

Figure 19-19. SIRC Bit Transmission Example

uart-020

This document does not describe all encoding methods and techniques; the preceding information shows the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol usage.

19.3 UART/IrDA/CIR Integration

Figure 19-20 shows the device internal connections with related modules for UART functions.

Figure 19-20. UART Functional Integration

uart-021

19.3.1 Clocking, Reset, and Power-Management Scheme

19.3.1.1 Clocking

Each UART uses a 48-MHz functional clock for its logic and the generation of external interface signals. Each UART uses an interface clock for register accesses. The power, reset, and clock management (PRCM) module generates and controls all these clocks (for more information, see [Chapter 3, Power, Reset, and Clock Management](#)).

[Table 19-11](#) describes the UART clocks.

Table 19-11. UART Clocks

Clock Type	Frequency	Name	Comments
UART1			
Functional clock	CORE_48M_FCLK	UART1_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN1_CORE[13] EN_UART1 bit.
Interface clock	CORE_L4_ICLK	UART1_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_ICLKEN1_CORE[13] EN_UART1 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE1_CORE[13] AUTO_UART1 bit.
UART2			
Functional clock	CORE_48M_FCLK	UART2_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN1_CORE[14] EN_UART2 bit.
Interface clock	CORE_L4_ICLK	UART2_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM. CM_ICLKEN1_CORE[14] EN_UART2 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE1_CORE[14] AUTO_UART2 bit.
UART3			
Functional clock	PER_48M_FCLK	UART3_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN_PER[11] EN_UART3 bit.
Interface clock	PER_L4_ICLK	UART3_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM. CM_ICLKEN_PER[11] EN_UART3 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE_ PER[11] AUTO_UART3 bit.
UART4			
Functional clock	PER_48M_FCLK	UART4_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN_PER[18] EN_UART4 bit.
Interface clock	PER_L4_ICLK	UART4_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM. CM_ICLKEN_PER[18] EN_UART4 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE_ PER[18] AUTO_UART4 bit.

The idle and wake-up processes use a handshake protocol between the PRCM module and the UARTs (for a description of the protocol, see [Chapter 3, Power, Reset, and Clock Management](#)). The **UARTi.SYSC_REG[4:3]** IDLEMODE field controls the UART idle mode.

19.3.1.2 Hardware Reset

[Table 19-12](#) lists the UART reset domain.

Table 19-12. Reset Domain

Peripherals	Reset Domain
UART1	CORE_RST
UART2	CORE_RST
UART3	PER_RST
UART4	PER_RST

19.3.1.3 Software Reset

The **UARTi.SYSC_REG[1]** SOFTRESET bit controls the software reset; writing 1 to this bit triggers a software-reset functionally equivalent to hardware reset.

19.3.1.4 Power Domain

Each UART in the CORE or PER power domain can dynamically switch between available voltage levels (see [Table 19-13](#)).

Table 19-13. Power Domain

Peripherals	Power Domain
UART1	CORE
UART2	CORE
UART3	PER
UART4	PER

19.3.2 Hardware Requests

19.3.2.1 Interrupts

[Table 19-14](#) describes the UART interrupt mappings.

Table 19-14. Interrupt Mapping to MPU Subsystem

IRQ	Source	Description
M_IRQ_72	UART1_IRQ	UART module 1 interrupt to MPU
M_IRQ_73	UART2_IRQ	UART module 2 interrupt to MPU
M_IRQ_74	UART3_IRQ	UART module 3 interrupt to MPU
M_IRQ_80	UART4_IRQ	UART module 4 interrupt to MPU

Table 19-15. Interrupt Mapping to IVA2.2 Subsystem

IRQ	SOURCE	DESCRIPTION
IVA2_IRQ[15]	UART3_IRQ	UART module 3 interrupt to IVA2.2 subsystem

19.3.2.2 DMA Requests

[Table 19-16](#) describes the UART DMA requests.

Table 19-16. UART DMA Requests to System DMA

DMA ⁽¹⁾	Source	Description
S_DMA_48	UART1_DMA_TX	UART module 1 transmit request
S_DMA_49	UART1_DMA_RX	UART module 1 receive request
S_DMA_50	UART2_DMA_TX	UART module 2 transmit request
S_DMA_51	UART2_DMA_RX	UART module 2 receive request
S_DMA_52	UART3_DMA_TX	UART module 3 transmit request
S_DMA_53	UART3_DMA_RX	UART module 3 receive request
S_DMA_80	UART4_DMA_TX	UART module 4 transmit request
S_DMA_81	UART4_DMA_RX	UART module 4 receive request

⁽¹⁾ This table assumes that DMA mode 1 is used.

Table 19-17. UART DMA Requests to IVA2.2 Subsystem DMA

DMA	SOURCE	DESCRIPTION
D_DMA_10	UART3_DMA_TX	UART module 3 transmit request
D_DMA_11	UART3_DMA_RX	UART module 3 receive request

19.3.2.3 Wake-up Request

The UART can wake up the system on different events (see [Section 19.6, UART/IrDA/CIR Register Manual](#)).

One important wake-up generation is event detection on the uart1_cts pin when the system is idle. The uart1_cts pin uses an asynchronous path to transmit the wake-up request to the system (PRCM), which enables wake-up capabilities to be active even if all module clocks are off (see [Table 19-18](#)).

Table 19-18. Wake-Up Requests From PRCM

Wake-Up Pin	PRCM Input	Description
uart1_cts	UART1_SWAKEUP	Wake UART1 (system wake-up capabilities)
uart2_cts	UART2_SWAKEUP	Wake UART2 (system wake-up capabilities)
uart3_cts	UART3_SWAKEUP	Wake UART3 (system wake-up capabilities)

CAUTION

UARTs are not in the WAKEUP power domain, which implies limitations on wake-up capability. If the CORE power domain is off, UART1 and UART2 cannot wake up the system, because power is not supplied. If the PER power domain is off, UART3 cannot wake up the system, because power is not supplied. In these cases, a GPIO multiplexed on the uart1_cts pin can be used to capture the event and wake up the system. Software must enable this strategy, if required. See [Chapter 25, General-Purpose Interface](#), for a full description of this mechanism.

19.4 UART/IrDA/CIR Functional Description

19.4.1 UART/IrDA/CIR Block Description

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two mode selections:

- Function mode selection: Route the data to the chosen functionality (UART, IrDA, or CIR) and enable the mechanism corresponding to the chosen functionality.
- Register mode selection, which enables conditional access to registers

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine, which assumes the transition between FIFO data and frame data.
- Interrupt management: Different interrupt types are generated depending on the chosen function.

In parallel with these functional blocks, a power-saving strategy exists for each function.

Figure 19-21 is the UART/IrDA/CIR block diagram.

Figure 19-21. UART/IrDA/CIR Block Diagram

19.4.2 FIFO Management

The FIFO is accessed by reading/writing the `UARTi.RHR_REG` and `UARTi.THR_REG` registers. Parameters are controlled using the FIFO control register (`UARTi.FCR_REG`) and supplementary control register (`UARTi.SCR_REG`). Reading the `UARTi.SSR_REG[0]` TX_FIFO_FULL bit at 1 means the FIFO is full.

The `UARTi.TLR_REG` register controls the FIFO trigger level, which enables the DMA and interrupt generation. After reset, both transmitter and receiver FIFOs are disabled; so, in effect, the trigger level is the default value of 1 byte. [Figure 19-22](#) shows the FIFO management registers.

NOTE: Data in the `UARTi.RHR_REG` register is not overwritten when an overflow occurs.

NOTE: The `UARTi.SFLSR_REG`, `UARTi.SFREGL_REG`, and `UARTi.SFREGH_REG` status registers are used in IrDA mode only. For use, see [Section 19.4.4.2.3, IrDA Data Formatting](#).

Figure 19-22. FIFO Management Registers

19.4.2.1 FIFO Trigger

19.4.2.1.1 Transmit FIFO Trigger

Table 19-19 summarizes the transmit FIFO trigger level settings.

Table 19-19. TX FIFO Trigger Level Setting Summary

SCR_REG[6]	TLR_REG[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi. FCR_REG [5:4] TX_FIFO_TRIG field (8,16, 32, or 56 spaces)
0	≠ 0x0	Defined by the UARTi. TLR_REG [3:0] TX_FIFO_TRIG_DMA field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) Note: The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one space required). All zeros result in unpredictable behavior.

19.4.2.1.2 Receive FIFO Trigger

Table 19-20 summarizes the receive FIFO trigger level settings.

Table 19-20. RX FIFO Trigger Level Setting Summary

SCR_REG[7]	TLR_REG[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi. FCR_REG [7:6] RX_FIFO_TRIG field (8,16, 56, or 60 characters)
0	≠ 0x0	Defined by UARTi. TLR_REG [7:4] RX_FIFO_TRIG_DMA field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character). Note: The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum 1 character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.[TCR_REG](#)[7:4] RX_FIFO_TRIG_START and UARTi.[TCR_REG](#)[3:0] RX_FIFO_TRIG_HALT fields.

- Trigger levels from 0 to 60 bytes are available with a granularity of four. (Trigger level = 4 × [4-bit register value])
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT > RX_FIFO_TRIG when auto-RTS is enabled.

$$\text{Delay} = [4 + 16 \times (1 + \text{CHAR_LENGTH} + \text{Parity} + \text{Stop} - 0.5)] \times \text{Baud_rate} + 4 \times \text{FCLK}$$

NOTE: The RTS signal is deasserted after the UART module receives the data over RX_FIFO_TRIG_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX_FIFO_TRIG_HALT.

- In the FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the receive FIFO trigger level (either the UARTi.[TCR_REG](#)[7:4] RX_FIFO_TRIG_START field or the UARTi.[FCR_REG](#)[7:6] RX_FIFO_TRIG field); otherwise, FIFO operation stalls. In the FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

19.4.2.2 FIFO Interrupt Mode

In the FIFO interrupt mode (the FIFO control register UARTi.[FCR_REG](#)[0] FIFO_EN bit is set to 1 and

relevant interrupts are enabled by the **UART_i.IER_REG** register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the receive/transmit FIFO threshold (the **UART_i.TLR_REG[7:4]** RX_FIFO_TRIG_DMA and **UART_i.TLR_REG[3:0]** TX_FIFO_TRIG_DMA fields or the **UART_i.FCR_REG[7:6]** RX_FIFO_TRIG and **UART_i.FCR_REG[5:4]** TX_FIFO_TRIG fields, respectively) is reached.

The interrupt signals instruct the MPU to transfer data to the destination (from the UART module in receive mode and/or from any source to the UART FIFO in transmit mode).

When the UART flow control is enabled with the interrupt capabilities, the UART flow control FIFO threshold (**UART_i.TCR_REG[3:0]** RX_FIFO_TRIG_HALT field) must be greater than or equal to the receive FIFO threshold.

[Figure 19-23](#) shows the generation of the receive FIFO interrupt request.

Figure 19-23. Receive FIFO Interrupt Request Generation

In receive mode, no interrupt is generated until the receive FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to make the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

[Figure 19-24](#) shows the generation of the transmit FIFO interrupt request.

Figure 19-24. Transmit FIFO Interrupt Request Generation

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

19.4.2.3 FIFO Polled Mode Operation

In the FIFO polled mode (the [UARTi.FCR_REG\[0\]](#) FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the [UARTi.IER_REG](#) register), the status of the receiver and transmitter can be checked by polling the line status register ([UARTi.LSR_REG](#)).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

19.4.2.4 FIFO DMA Mode Operation

Although DMA operation includes four modes (DMA modes 0/1/2/3), the information in [Table 19-16](#) assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

The DMA requests in mode 2 and mode 3 use S_DMA_48, S_DMA_50, and S_DMA_52/D_DMA_10. S_DMA_49, S_DMA_51, and S_DMA_53/D_DMA_11 are not used by the module in mode 2 and mode 3 and can be selected as follows:

- When the [UARTi.SCR_REG\[0\]](#) DMA_MODE_CTL bit is set to 0, setting the [UARTi.FCR_REG\[3\]](#) DMA_MODE bit to 0 enables DMA mode 0. Setting the DMA_MODE bit to 1 enables DMA mode 1.
- When the DMA_MODE_CTL bit is set to 1, the [UARTi.FCR_REG\[2:1\]](#) DMA_MODE_2 field determines DMA mode 0 to 3 based on the supplementary control register ([SCR_REG](#)) description.

For example:

- If no DMA operation is desired, set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 field to 0x0. (The DMA_MODE bit is discarded.)
- If DMA mode 1 is desired, set either the DMA_MODE_CTL bit to 0 and the DMA_MODE bit to 1, or set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 field to 01. (The DMA_MODE bit is discarded.)

If the FIFOs are disabled (the [UARTi.FCR_REG\[0\]](#) FIFO_EN bit = 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

19.4.2.4.1 DMA Transfers (DMA Mode 1, 2, or 3)

[Figure 19-25](#) through [Figure 19-28](#) show the supported DMA operations.

Figure 19-25. Receive FIFO DMA Request Generation (32 Characters)

In receive mode, a DMA request is generated when the receive FIFO reaches its threshold level defined in the trigger level register (UART_i.[TLR_REG](#)). This request is deasserted when the number of bytes defined by the threshold level is read by the system DMA (sDMA).

In transmit mode, a DMA request is automatically asserted when the transmit FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the trigger level register (UART_i.[TLR_REG](#)) is written by the sDMA. If an insufficient number of characters is written, the DMA request stays active.

Figure 19-26. Transmit FIFO DMA Request Generation (56 Spaces)

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the `UARTi.TLR_REG` register.

The threshold can be programmed in a number of ways. [Figure 19-26](#) shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the `UARTi.FCR_REG[5:4]` TX_FIFO_TRIG field or the `UARTi.TLR_REG[3:0]` TX_FIFO_TRIG_DMA field concatenated with the TX_FIFO_TRIG field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the sDMA so that the buffer does not overflow (program the DMA request size of the local host controller to be equal to the number of spaces value in the UART/IrDA/CIR module).

[Figure 19-27](#) shows an example with eight spaces to show the buffer level crossing the space threshold. Again, the local host DMA controller settings must correspond to that of the UART/IrDA/CIR module.

Figure 19-27. Transmit FIFO DMA Request Generation (8 Spaces)

The final example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see [Figure 19-28](#)). The buffer is filled at a faster rate than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the `UARTi.DLL_REG` and the `UARTi.DLH_REG` registers.

Again, the DMA settings must correspond to the system local host DMA controller settings to ensure correct operation of this logic.

Figure 19-28. Transmit FIFO DMA Request Generation (1 Space)

uart-029

19.4.2.4.2 DMA Transmission

Figure 19-29 shows the DMA transmission process.

Figure 19-29. Transmission Process

uart-030

- Data to be transmitted are put in the device memory reserved for UART/IrDA/CIR transmission by the DMA:
 - Until the TX FIFO trigger level is not reached, a DMA request is generated.
 - An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
- Data in the TX FIFO are automatically transmitted.
- The end of the transmission is signaled by the [UARTi.THR_REG](#) empty (TX FIFO empty).

NOTE: In IrDA mode, the transmission is not ended immediately after the TX FIFO empties, at which point there are still the last data byte, the CRC field, and the stop flag to be transmitted; thus, the end of transmission is a few milliseconds after the [UARTi.THR_REG](#) register empties.

19.4.2.4.3 DMA Reception

Figure 19-30 shows the DMA reception process.

Figure 19-30. Reception Process

uart-031

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA.
 - At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
 - An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

19.4.3 Mode Selection

19.4.3.1 Register Access Modes

19.4.3.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Both configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only in the initialization step or reconfiguration of the module.

The value of the `UARTi.LCR_REG` register determines the register access mode (see [Table 19-21](#)).

Table 19-21. UART/IrDA/CIR Register Access Mode Programming (Using LCR_REG)

Mode	Condition
Configuration_mode_A	<code>LCR_REG[7] = 0x1</code> and <code>LCR_REG[7:0]! = 0xBF</code>
Configuration_mode_B	<code>LCR_REG[7] = 0x1</code> and <code>LCR_REG[7:0] = 0xBF</code>
Operational_mode	<code>LCR_REG[7] = 0x0</code>

19.4.3.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional to the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in [Section 19.6, UART/IrDA/CIR Register Manual](#).

[Table 19-22](#) through [Table 19-24](#) summarize the register access submodes.

Table 19-22. Sub-Configuration_Mode_A Mode Summary

Mode	Condition
MSR_SPR	(EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0)
TCR_TLR	EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1

Table 19-23. Sub-Configuration_Mode_B Mode Summary

Mode	Condition
TCR_TLR	EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1
XOFF	(EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0)

Table 19-24. Sub-Operational_Mode Mode Summary

Mode	Condition
MSR_SPR	EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0
TCR_TLR	EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1

19.4.3.1.3 Registers Available to Register Access Modes

[Table 19-25](#) lists the names of the register hits in each access register mode. Gray-shaded registers do not depend on the register access mode (available in all modes).

Table 19-25. UART/IrDA/CIR Register Access Mode Overview

19.4.3.2 UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the **UARTi.MDR1_REG[2:0]** MODE_SELECT field (see [Table 19-26](#)).

Table 19-26. UART Mode Selection

Value	Mode
0x0:	UART 16x mode
0x1:	SIR mode (UART3 only)
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	MIR mode (UART3 only)
0x5:	FIR mode (UART3 only)
0x6:	CIR mode (UART3 only)

MODE_SELECT is effective when the module is in operational mode (see [Section 19.4.3.1, Register Access Modes](#)).

19.4.3.2.1 Registers Available for the UART Function

Only the registers listed in [Table 19-27](#) are used for the UART function.

Table 19-27. UART Mode Register Overview⁽¹⁾ ⁽²⁾

19.4.4 Protocol Formatting

19.4.4.1 UART Mode

19.4.4.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 19-31 shows the baud rate generator and associated controls.

Figure 19-31. Baud Rate Generation

CAUTION

It is mandatory that MODE_SELECT = DISABLE (UARTi.MDR1_REG[2:0] = 0x7) before initializing or modifying clock parameter controls (UARTi.DLH_REG, UARTi.DLL_REG). Failure to observe this rule can result in unpredictable module behavior.

19.4.4.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency/(16x baud rate)
- UART 13x mode: Divisor value = Operating frequency/(13x baud rate)

[Table 19-30](#) describes the UART baud rate settings.

Table 19-30. UART Baud Rate Settings (48-MHz Clock)

Baud Rate	Baud Multiple	DLH,DLL (Decimal)	DLH,DLL (Hex)	Actual Baud Rate	Error (%)
0.3 Kbps	16x	10000	0x27, 0x10	0.3 Kbps	0
0.6 Kbps	16x	5000	0x13, 0x88	0.6 Kbps	0
1.2 Kbps	16x	2500	0x09, 0xC4	1.2 Kbps	0
2.4 Kbps	16x	1250	0x04, 0xE2	2.4 Kbps	0
4.8 Kbps	16x	625	0x02, 0x71	4.8 Kbps	0
9.6 Kbps	16x	312	0x01, 0x38	9.6153 Kbps	+0.16
14.4 Kbps	16x	208	0x00, 0xD0	14.423 Kbps	+0.16

460.8 Kbps	13x	8	0x00, 0x08	461.54 Kbps	+0.16
921.6 Kbps	13x	4	0x00, 0x04	923.08 Kbps	+0.16
1.843 Mbps	13x	2	0x00, 0x02	1.846 Mbps	+0.16
3.6884 Mbps	13x	1	0x00, 0x01	3.6923 Mbps	+0.16

19.4.4.1.3 UART Data Formatting

The UART module can use hardware flow control to manage transmission/reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART module is enhanced with the autobauding function. In control mode, autobauding allows the speed, the number of bits per character, and the parity selected to be set automatically.

19.4.4.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the [UARTi.LCR_REG](#) register.

Character length is specified using the [UARTi.LCR_REG\[1:0\]](#) CHAR_LENGTH field.

The number of stop bits is specified using the [UARTi.LCR_REG\[2\]](#) NB_STOP register bit.

The parity bit is programmed using the [UARTi.LCR_REG\[5:3\]](#) PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 register bits (see [Table 19-31](#)).

Table 19-31. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE1	PARITY_TYPE2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

19.4.4.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled/disabled independently by programming the UARTi.[EFR_REG\[7:6\]](#) AUTO_CTS_EN and AUTO_RTS_EN bits, respectively.

With auto-CTS, uarti_cts must be active before the module can transmit data.

Auto-RTS activates the uarti_rts output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti_rts output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.[TCR_REG](#) register determine the levels at which uarti_rts is activated/deactivated.

If both auto-CTS and auto-RTS are enabled, data transmission does not occur unless the receiver FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the receive FIFO latency.

- **Auto-RTS**

Auto-RTS data flow control originates in the receiver block. The receiver FIFO trigger levels used in auto-RTS are stored in the UARTi.[TCR_REG](#) register. uarti_rts is active if the RX FIFO level is below the HALT trigger level in the UARTi.[TCR_REG\[3:0\]](#) RX_FIFO_TRIG_HALTI field. When the receiver FIFO HALT trigger level is reached, uarti_rts is deasserted. The sending device (for example, another UART) might send an additional byte after the trigger level is reached because it might not recognize the deassertion of RTS until it begins sending the additional byte.

uarti_rts is automatically reasserted when the receiver FIFO reaches the RESUME trigger level programmed by the UARTi.[TCR_REG\[7:4\]](#) RX_FIFO_TRIG_START field. This reassertion requests the sending device to resume transmission.

In this case, uarti_rts is an active-low signal.

- **Auto-CTS**

The transmitter circuitry checks uarti_cts before sending the next data byte. When uarti_cts is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti_cts must be deasserted before the middle of the last stop bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti_cts state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, uarti_cts is an active-low signal.

19.4.4.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.[EFR_REG](#)) and the modem control register (UARTi.[MCR_REG](#)). Different combinations of software flow control can be enabled by setting different combinations of UARTi.[EFR_REG\[3:0\]](#) (see [Table 19-32](#)).

Two other enhanced features relate to software flow control:

- XON any function (UARTi.[MCR_REG\[5\]](#)): Operation resumes after receiving any character after recognition of the XOFF character. If special character detect is enabled and a special character is received after XOFF1, transmission is not resumed. The special character is stored in the RX FIFO.

NOTE: The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UARTi.[EFR_REG\[5\]](#)): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.[IIR_REG\[4\]](#)) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.[IIR_REG](#). The special character is transferred to the RX FIFO. The special character feature does not work with XON2, XOFF2, or sequential XOFFs.

Table 19-32. EFR_REG[0-3] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	Tx, Rx Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1

Table 19-32. EFR_REG[0-3] Software Flow Control Options (continued)

Bit 3	Bit 2	Bit 1	Bit 0	Tx, Rx Software Flow Controls
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 ⁽¹⁾
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 ⁽¹⁾

⁽¹⁾ In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.

XON1 is defined in the `UARTi.XON1_ADDR1_REG[7:0]` XON_WORD1 field, XON2 is defined in `UARTi.XON2_ADDR2_REG[7:0]` XON_WORD2.

XOFF1 is defined in the `UARTi.XOFF1_REG[7:0]` XOFF_WORD1 field, XOFF2 is defined in `UARTi.XOFF2_REG[7:0]` XOFF_WORD2.

19.4.4.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character is complete. XOFF detection also sets `UARTi.IIR_REG[4]` (if enabled by `UARTi.IER_REG[5]`) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, `UARTi.IIR_REG[4]` is cleared and the XOFF interrupt disappears.

NOTE: When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when `UARTi.EFR_REG[1:0] = 0x2`, if XON1 and XOFF1 characters are received, they do not get written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (`UARTi.EFR_REG[1:0] = 0x3`), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

19.4.4.1.3.3.2 Transmit (TX)

XOFF1: Two characters are transmitted when the RX FIFO passes the trigger level programmed by `UARTi.TCR_REG[3:0]`.

XON1: Two characters are transmitted when the RX FIFO reaches the trigger level programmed by `UARTi.TCR_REG[7:4]`.

NOTE: If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission to proceed.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is set to 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

19.4.4.1.3.4 Autobaunding Modes

In autobaunding mode, the UART can extract transfer characteristics (speed, length, and parity) from an AT command (ASCII code). These characteristics are used to receive data after an "at" (AT) and to send data.

The valid AT commands follow:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and echo functionality is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. Either A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to RX FIFO. The autobaunding state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved into RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The [UARTi.UASR_REG](#) register reflects the correct settings for the baud rate detected. The interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaunding mode.

The following settings are detected in autobaunding mode with a module clock of 48 MHz:

- Speed: 115.2k baud, 57.6k baud, 38.4k baud, 28.8k baud, 19.2k baud, 14.4k baud, 9.6k baud, 4.8k baud, 2.4k baud, or 1.2k baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character + space parity is not supported.

Autobaunding mode is selected when the [UARTi.MDR1_REG\[2:0\]](#) MODE_SELECT field is set to 0x2. In the UART autobaunding mode, [UARTi.DLL_REG](#), [UARTi.DLH_REG](#), [UARTi.LCR_REG\[5:0\]](#) settings are not used; instead, [UASR_REG](#) is updated with the configuration detected by the autobaunding logic.

[UASR_REG](#) Autobaunding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the [UARTi.LCR_REG](#), [UARTi.DLL_REG](#), and [UARTi.DLH_REG](#) registers when the UART is in autobaunding mode.

To reset the autobaunding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaunding), the [UARTi.MDR1_REG\[2:0\]](#) MODE_SELECT field must be set to reset state (0x7) and then to the UART in autobaunding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1,200 and 115,200 bps (10 possibilities)

19.4.4.1.3.5 Error Detection

When the `UARTi.LSR_REG` register is read, `UARTi.LSR_REG[4:2]` reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (next character to be read). Therefore, reading the `UARTi.LSR_REG` register and then reading the `UARTi.RHR_REG` register identifies errors in a character.

Reading the `UARTi.RHR_REG` register updates the BI, FE, and PE bits (see [Table 19-33](#) for the UART mode interrupts).

The `UARTi.LSR_REG [7] RX_FIFO_STS` bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

NOTE: Reading `UARTi.LSR_REG` does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading `UARTi.RHR_REG`.

Reading `UARTi.LSR_REG` clears the OE bit if it is set (see [Table 19-33](#) for the UART mode interrupts).

19.4.4.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPU with `UARTi.IIR_REG[5:1] IT_TYPE = 0x3` (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the system (MPU) must:

- Reset the RX FIFO
- Read the `UARTi.RESUME_REG` register (which clears the internal flag)

19.4.4.1.3.7 Time-Out and Break Conditions

19.4.4.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (`uarti_rx`) is high for a time equivalent to $4 \times$ programmed word length + 12 bits. `uarti_rx` is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on `uarti_rx`.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on `uarti_rx` or when the `UARTi.RHR_REG` is read.

19.4.4.1.3.7.2 Break Condition

When a break condition occurs, `uarti_tx` is pulled low. A break condition is activated by setting the `UARTi.LCR_REG[6] BREAK_EN` bit. The break condition is not aligned on word stream (that is, a break condition can occur in the middle of a character). The only way to send a break condition on a full character is as follows:

1. Reset the transmit FIFO (if enabled).
2. Wait for the transmit shift register to empty (`UARTi.LSR_REG[6] TX_SR_E = 1`).
3. Take a guard time according to stop-bit definition.
4. Set the `BREAK_EN` bit to 1.

The break condition is asserted while the `BREAK_EN` bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

19.4.4.1.4 UART Mode Interrupt Management

The UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UART*i*.[IIR_REG](#)) sets the UART*i*.[IIR_REG\[0\]](#) IT_PENDING bit to 0 to indicate that an interrupt is pending, and provides the type of interrupt through UART*i*.[IIR_REG\[5:1\]](#). [Table 19-33](#) summarizes the interrupt control functions.

Table 19-33. UART Mode Interrupts

IIR_REG[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	None	None	None	None
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read RHR_REG . OE: Read LSR_REG .
001100	2	RX time-out	Stale data in RX FIFO	Read RHR_REG .
000100	2	RHR interrupt	DRDY (data ready) (FIFO disable)	Read RHR_REG until interrupt condition disappears.
			RX FIFO above trigger level (FIFO enable)	
000010	3	THR interrupt	TFE (THR_REG empty) (FIFO disable)	Write to THR_REG until interrupt condition disappears.
			TX FIFO below trigger level (FIFO enable)	
000000	4	Modem status	See the MSR_REG register.	Read MSR_REG .
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of IIR_REG , if special character interrupt.
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high).	Read IIR_REG .

For the receiver-line status interrupt, the RX_FIFO_STS bit (UART*i*.[LSR_REG\[7\]](#)) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UART*i*.[IIR_REG](#) register.

19.4.4.1.4.1 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that is not designed the same way as other interrupts. This interrupt is enabled when the UART*i*.[SCR_REG\[4\]](#) RX_CTS_WU_EN bit is set to 1. The UART*i*.[IIR_REG](#) register is not modified when it occurs; the UART3.[SSR_REG\[1\]](#) RX_CTS_WU_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, the only way to clear it is to reset the UART*i*.[SCR_REG\[4\]](#) RX_CTS_WU_EN bit. This bit must be re-enabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

19.4.4.2 IrDA Mode (UART3 Only)

19.4.4.2.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

[Figure 19-32](#) shows the baud rate generator and associated controls.

Figure 19-32. Baud Rate Generator

uart-033

CAUTION

Before trying to initialize or modify clock parameter controls (UARTi.DLH_REG, UARTi.DLL_REG), it is mandatory to set MODE_SELECT=DISABLE (UARTi.MDR1_REG[2:0]=0x7).

Failure to observe this rule can result in unpredictable module behavior.

19.4.4.2.2 Choosing the Appropriate Divisor Value

- SIR mode: Divisor value = Operating frequency/(16x baud rate)
- MIR mode: Divisor value = Operating frequency/(41x/42x baud rate)
- FIR mode: Divisor value = None

[Table 19-34](#) lists the IrDA baud rate settings.

Table 19-34. IrDA Baud Rates Settings

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)\$	Source Jitter (%)	Pulse duration
2.4 Kbps	SIR	16x	3/16	1250	2.4 Kbps	0	0	78.1 μ s
9.6 Kbps	SIR	16x	3/16	312	9.6153 Kbps	+0.16	0	19.5 μ s
19.2 Kbps	SIR	16x	3/16	156	19.231 Kbps	+0.16	0	9.75 μ s
38.4 Kbps	SIR	16x	3/16	78	38.462 Kbps	+0.16	0	4.87 μ s
57.6 Kbps	SIR	16x	3/16	52	57.692 Kbps	+0.16	0	3.25 μ s
115.2 Kbps	SIR	16x	3/16	26	115.38 Kbps	+0.16	0	1.62 μ s

Table 19-34. IrDA Baud Rates Settings (continued)

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%\$)	Source Jitter (%)	Pulse duration
0.576 Mbps	MIR	41x/42x	1/4	2	0.5756 Mbps ⁽¹⁾	0	+1.63/- 0.80	416 ns
1.152 Mbps	MIR	41x/42x	1/4	1	1.1511 Mbps ⁽¹⁾	0	+1.63/- 0.80	208 ns
4 Mbps	FIR	6x	4 PPM	-	4 Mbps	0	0	125 ns

⁽¹⁾ Average value

NOTE: Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

19.4.4.2.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

19.4.4.2.3.1 IRRX Polarity Control

The UART3.[MDR2_REG](#)[6] IRRXINVERT bit provides the flexibility to invert the uart3_rx_irrx pin in the UART module to ensure that the protocol at the output of the transceiver module has the same polarity at module level. By default, the uart3_rx_irrx pin is inverted because most transceivers invert the IR receive pin.

19.4.4.2.3.2 IrDA Reception Control

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the uart3_rx_irrx input can be disabled by the UART3.[ACREG_REG](#)[5] DIS_IR_RX bit.

19.4.4.2.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives with the UART3.[XON1_ADDR1_REG](#)[7:0] XON_WORD1 and UART3.[XON2_ADDR2_REG](#)[7:0] XON_WORD2 fields.

Setting the [EFR_REG](#)[0] bit to 1 selects address1 checking. Setting the [EFR_REG](#)[1] bit to 1 selects address2 checking. Setting the [EFR_REG](#)[1:0] bit to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for both private and public addresses.

If address checking is disabled, all received frames write to the reception FIFO.

19.4.4.2.3.4 Frame Closing

A transmission frame can be correctly terminated in two ways:

- Frame-length method: The frame-length method is selected by setting the UART3.[MDR1_REG](#)[7] FRAME_END_MODE bit to 0. The MPU writes the frame-length value to the UART3.[TXFLH_REG](#) and UART3.[TXFLL_REG](#) registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the frame-length value.
- Set-EOT bit method: The set-EOT bit method is selected by setting the FRAME_END_MODE bit to 1. The MPU writes 1 to the UART3.[ACREG_REG](#)[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

19.4.4.2.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or a whole frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UART3.[ACREG_REG\[2\]](#) SCTX_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART3.[MDR1_REG\[5\]](#) SCT bit to 1. This transmission method is different from the normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

19.4.4.2.3.6 Error Detection

When the UART3.[LSR_REG](#) register is read, the UART3.[LSR_REG\[4:2\]](#) field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (see [Table 19-35](#) for IrDA mode interrupts). STATUS FIFO must be read until empty (a maximum of eight reads is required).

19.4.4.2.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the system (MPU) must:

- Reset the TX FIFO.
- Read the UART3.[RESUME_REG](#) register (which clears the internal flag).

This functionality can be disabled by the UART3.[ACREG_REG\[4\]](#) DIS_TX_UNDERRUN bit, compensated by the extension of the stop bit in transmission if the TX FIFO is empty.

19.4.4.2.3.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same functionality as that for the UART mode (see [Section 19.4.4.1.3.6, Overrun During Receive](#)).

19.4.4.2.3.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading UART3.[SFREGH_REG\[3:0\]](#) (MSB) and UART3.[SFREGL_REG\[3:0\]](#) (LSB) obtains the frame length. The frame error status is read in the UART3.[SFLSR_REG](#) register. Reading the UART3.[SFLSR_REG](#) register increments the status FIFO read pointer. The status FIFO is eight entries deep and, therefore, can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the MPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

19.4.4.2.4 SIR Mode DATA Formatting

This section provides specific instructions for SIR mode programming.

19.4.4.2.4.1 Abort Sequence

When the transmitter prematurely closes a frame, it sends the following sequence to abort: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART3.[ACREG_REG\[1\]](#) ABORT_EN bit to 1.

When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

The receiver treats a frame as an aborted frame when a 0x7D character followed immediately by a 0xC1 character is received without transparency.

CAUTION

When the transmit FIFO is not empty and the UART3.[MDR1_REG\[5\]](#) SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the abort frame is sent. Therefore, TX FIFO must be reset before sending an abort frame.

19.4.4.2.4.2 Pulse Shaping

The SIR mode supports both the 3/16th or the 1.6- μ s pulse duration methods in receive and transmit. The UART3.[ACREG_REG\[7\]](#) PULSE_TYPE bit selects the pulse width method in the transmit mode.

19.4.4.2.4.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UART3.[MDR1_REG\[2:0\]](#) MODE_SELECT = 0x0) and the UART3.[MDR2_REG\[3\]](#) UART_PULSE bit to 1 to allow pulse shaping.

Because the bit format remains the same, some UART mode configuration registers must be set at specific values:

- UART3.[LCR_REG\[1:0\]](#) CHAR_LENGTH field = 0x3 (8 data bits)
- UART3.[LCR_REG\[2\]](#) NB_STOP bit = 0x0 (1 stop-bit)
- UART3.[LCR_REG\[3\]](#) PARITY_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many of them are not relevant (XOFF, RTS, CTS, modem status register, etc.).

19.4.4.2.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UART3.[LSR_REG](#)) to detect possible errors in the received frame.

When the UART3.[MDR1_REG\[6\]](#) SIP_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP_MODE bit is set to 0, SIP transmission depends on the UART3.[ACREG_REG\[3\]](#) SEND_SIP bit.

The system (MPU) can set the SEND_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, which can reduce the overhead required.

19.4.4.2.6 IrDA Mode Interrupt Management

19.4.4.2.6.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (UART3.[IER_REG](#)). The interrupt status of the device can be checked at any time by reading the interrupt identification register (UART3.[IIR_REG](#)).

The UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.[IER_REG](#) and UART3.[IIR_REG](#) mappings, depending on the selected mode.

The IrDA modes have eight possible interrupts (see [Table 19-35](#)). The interrupt line is activated when any of the eight interrupts is generated (there is no priority).

Table 19-35. IrDA Mode Interrupts

IIR_REG Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read RHR_REG until interrupt condition disappears.
1	THR interrupt	TFE (THR_REG empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR_REG until interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read RHR_REG.
3	RX overrun	Write to RHR_REG when RX FIFO full.	Read RESUME_REG register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	1. THR_REG empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully.	1. Read RESUME_REG register. OR 2. Read IIR_REG.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into STATUS FIFO.	Read STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame.	Read IIR_REG.

19.4.4.2.6.2 Wake-Up Interrupts

The wake-up interrupt for the IrDA mode has the same functionality as that for the UART mode (see Section 19.4.4.1.4.1, *Wake-Up Interrupt*).

CAUTION

Wake-up interface implementation in this mode is based on the UARTi_SIDLEACK low-to-high transition instead of the UARTi_SIDLEACK state.

This does not ensure wake-up event generation as expected when configured in smart-idle mode and the system wakes up for a short period.

19.4.4.3 CIR Mode (UART3 Only)

19.4.4.3.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the MPU must develop a data structure that combines 1 and 0 with a t period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in Figure 19-33.

Figure 19-33. CIR Mode Block Components

uart-034

Based on the requested modulation frequency, the **UART3.CFPS_REG** register must be set with the correct dividing value to provide the more accurate pulse frequency:

$$\text{Dividing value} = (\text{FCLK}/12)/\text{MODfreq}$$

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the **CFPS_REG** value must be set to 111 (decimal), which provides a modulation frequency of 36.04 kHz.

NOTE: The **UART3.CFPS_REG** register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the **UART3.MDR2_REG** configuration register. **Table 19-36** shows the duty cycle.

Table 19-36. Duty Cycle

MDR2_REG[5:4]	Duty Cycle (High Level)
00	1/4
01	1/3
10	5/12
11	1/2

19.4.4.3.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

19.4.4.3.2.1 IRRX Polarity Control

The IRRX polarity control for the CIR mode has the same functionality as that for the IrDA mode (see Section 19.4.4.2.3.1, *IRRX Polarity Control*).

19.4.4.3.2.2 CIR Transmission

In transmission, the MPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a t period
- Using an external system timer to control the delay either between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
 - Controlling the start of the frame using the UART3.MDR1_REG[5] SCT bit and UART3.ACREG_REG[2] SCTX_EN bit, depending on the timer status
 - Using the UART3.IIR_REG[5] TX_STATUS_IT interrupt to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame).

19.4.4.3.2.3 CIR Reception

There are two methods of stopping reception:

- The MPU can disable the reception by setting the UART3.ACREG_REG[5] DIS_IR_RX bit to 1 when it detects that the reception is complete because of the large number of 0s received. To receive a new frame, the DIS_IR_RX bit must be set to 0.
- The reception stops automatically, depending on the value set in the BOF-length register (the UART3.EBLR_REG[7:0] EBLR field). If the value set in the UART3.EBLR_REG[7:0] EBLR field is different from 0, this feature is enabled and counts the number of bits received at 0.

When the counter achieves the value defined in the EBLR_REG register, the reception automatically stops and the UART3.IIR_REG[2] RX_STOP_IT bit is set. When 1 is detected on the uart3.rx_irrx pin, the reception is automatically enabled.

CAUTION

If the UART3.IER_REG[2] RX_STOP_IT interrupt occurs before a byte boundary, the remaining bits of the last byte are filled with zeros and then passed into the RX FIFO.

19.4.4.3.3 CIR Mode Interrupt Management

19.4.4.3.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (UART3.[IER_REG](#)). The interrupt status of the device can be checked at any time by reading the interrupt identification register (UART3.[IIR_REG](#)).

The UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.[IER_REG](#) and UART3.[IIR_REG](#) mappings, depending on the selected mode.

[Table 19-37](#) lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART3.[IIR_REG](#)[5] bit is to indicate that the last bit of infrared data was passed to the uart3_cts_rctx pin.

Table 19-37. CIR Mode Interrupts

IIR_REG Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
1	THR interrupt	TFE (THR_REG empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR_REG until interrupt condition disappears.
2	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
3	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is completed successfully.	Read IIR_REG .
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

19.4.4.3.3.2 Wake-Up Interrupts

The wake-up interrupt for the IrDA mode has the same functionality as that for the UART mode (see [Section 19.4.4.1.4.1, Wake-Up Interrupt](#)).

19.4.5 Power Management

19.4.5.1 UART Mode Power Management

19.4.5.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the [UART*i*.IER_REG](#)[4] SLEEP_MODE bit to 1 (when the [UART*i*.EFR_REG](#)[4] ENHANCED_EN bit is set to 1).

Sleep mode is entered when all the following conditions exist:

- The serial data input line, [uart*i*_rx](#), is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

Sleep mode is a good way to lower power consumption of the UART, but this state can be achieved only when the UART is set in modem mode. Therefore, even if the UART has no functional key role, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked using these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the [uart*i*_rx](#) line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UARTi.[SCR_REG\[4\]](#) RX_CTS_WU_EN bit to 1. See [Section 19.4.4.1.4.1, Wake-Up Interrupt](#), to understand how to manage the interrupt.

NOTE: There must be no writing to the divisor latches, UARTi.[DLL_REG](#) and UARTi.[DLH_REG](#), to set the baud clock, BCLK, while in sleep mode. It is advisable to disable sleep mode using the UARTi.[IER_REG\[4\]](#) SLEEP_MODE bit before writing to the UARTi.[DLL_REG](#) register or the UARTi.[DLH_REG](#) register.

19.4.5.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. At the system level, power-reduction techniques can be applied by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol. This protocol is used at the system level to shut down clocks of the UART in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UARTi.[SYSC_REG\[2\]](#) ENAWAKEUP bit and the UARTi.[WER_REG](#) register).

For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

19.4.5.2 IrDA Mode Power Management (UART3 Only)

19.4.5.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART3.MDR[3] IR_SLEEP bit to 1.

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uart3.rx_irrx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the uart3_rx_irrx line or when data is written to the TX FIFO.

19.4.5.2.2 System Power Saving

System power saving for the IrDA mode has the same functionality as that for the UART mode (see [Section 19.4.5.1.2, System Power Saving](#)).

19.4.5.3 CIR Mode Power Management (UART3 Only)

19.4.5.3.1 Module Power Saving

Module power saving for the CIR mode has the same functionality as that for the IrDA mode (see [Section 19.4.5.2.1, Module Power Saving](#)).

19.4.5.3.2 System Power Saving

System power saving for the CIR mode has the same functionality as that for the UART mode (see [Section 19.4.5.2.2, System Power Saving](#)).

19.5 UART/IrDA/CIR Basic Programming Model

19.5.1 UART Programming Model

19.5.1.1 Quick start

This section outlines the procedure for operating the UART module with FIFO and DMA or interrupts. This 3-part procedure ensures the quick start of the UART module. It does not cover every UART module feature.

The first programming model covers software reset of the module. The second programming model deals with FIFO and DMA configuration. The last programming model deals with protocol, baud rate and interrupt configuration.

NOTE: Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information see [Section 19.4.3.1, Register Access Modes](#).

19.5.1.1.1 Software Reset

To clear the UART registers, perform the following steps:

1. Initiate a software reset:

Set the `UARTi.SYSC_REG[1]` SOFTRESET bit to 1.

2. Wait for the end of the reset operation:

Poll the `UARTi.SYSS_REG[0]` RESETDONE bit until it equals 1.

19.5.1.1.2 FIFOs and DMA Settings

To enable and configure the receive and transmit FIFOs and program the DMA mode, perform the following steps:

1. Switch to register configuration mode B to access the `UARTi.EFR_REG` register:

(a) Save the current `UARTi.LCR_REG` value.

(b) Set `UARTi.LCR_REG` to 0x00BF.

2. Enable register submode TCR_TLR to access `UARTi.TLR_REG` (part 1 of 2):

(a) Save the `UARTi.EFR_REG[4]` ENHANCED_EN value.

(b) Set the `UARTi.EFR_REG[4]` ENHANCED_EN bit to 1.

3. Switch to register configuration mode A to access the `UARTi.MCR_REG` register:

Set `UARTi.LCR_REG` to 0x0080.

4. Enable register submode TCR_TLR to access `UARTi.TLR_REG` (part 2 of 2):

(a) Save the `UARTi.MCR_REG[6]` TCR_TLR value.

(b) Set the `UARTi.MCR_REG[6]` TCR_TLR bit to 1.

5. Enable FIFO, load the new FIFO triggers (part 1 of 3) and the new DMA mode (part 1 of 2):

Set the following bits to the desired values:

- `UARTi.FCR_REG[7:6]` RX_FIFO_TRIG

- `UARTi.FCR_REG[5:4]` TX_FIFO_TRIG

- `UARTi.FCR_REG[3]` DMA_MODE

- `UARTi.FCR_REG[0]` FIFO_ENABLE (0: Disable the FIFO/1: Enable the FIFO)

NOTE: The `UARTi.FCR_REG` register is not readable.

6. Switch to register configuration mode B to access the `UARTi.EFR_REG` register:
Set `UARTi.LCR_REG` to 0x00BF.
7. Load the new FIFO triggers (part 2 of 3):
Set the following bits to the desired values:
 - `UARTi.TLR_REG[7:4]` RX_FIFO_TRIG_DMA
 - `UARTi.TLR_REG[3:0]` TX_FIFO_TRIG_DMA
8. Load the new FIFO triggers (part 3 of 3) and the new DMA mode (part 2 of 2):
Set the following bits to the desired values:
 - `UARTi.SCR_REG[7]` RX_TRIG_GRANU1
 - `UARTi.SCR_REG[6]` TX_TRIG_GRANU1
 - `UARTi.SCR_REG[2:1]` DMA_MODE_2
 - `UARTi.SCR_REG[0]` DMA_MODE_CTL
9. Restore the `UARTi.EFR_REG[4]` ENHANCED_EN value saved in Step 2a.
10. Switch to register configuration mode A to access the `UARTi.MCR_REG` register:
Set `UARTi.LCR_REG` to 0x0080.
11. Restore the `UARTi.MCR_REG[6]` TCR_TLR value saved in Step 4a.
12. Restore the `UARTi.LCR_REG` value saved in Step 1a.

Triggers are used to generate interrupt and DMA requests. See [Section 19.4.2.1.1, Transmit FIFO Trigger](#), to choose the following values:

- `UARTi.FCR_REG[5:4]` TX_FIFO_TRIG
- `UARTi.TLR_REG[3:0]` TX_FIFO_TRIG_DMA
- `UARTi.SCR_REG[6]` TX_TRIG_GRANU1

Triggers are used to generate interrupt and DMA requests. See [Section 19.4.2.1.2, Receive FIFO Trigger](#), to choose the following values:

- `UARTi.FCR_REG[7:6]` RX_FIFO_TRIG
- `UARTi.TLR_REG[7:4]` RX_FIFO_TRIG_DMA
- `UARTi.SCR_REG[7]` RX_TRIG_GRANU1

DMA mode enables the different DMA requests. See [Section 19.4.2.4, FIFO DMA Mode Operation](#), to choose the following values:

- `UARTi.FCR_REG[3]` DMA_MODE
- `UARTi.SCR_REG[2:1]` DMA_MODE_2
- `UARTi.SCR_REG[0]` DMA_MODE_CTL

19.5.1.1.3 Protocol, Baud Rate, and Interrupt Settings

To program the protocol, baud rate and interrupt settings, perform the following steps:

1. Disable UART to access `UARTi.DLL_REG` and `UARTi.DLH_REG`:
Set `UARTi.MDR1_REG[2:0]` MODE_SELECT to 0x7.
2. Switch to register configuration mode B to access the `UARTi.EFR_REG` register:
Set `UARTi.LCR_REG` to 0x00BF.
3. Enable access to `UARTi.IER_REG[7:4]`:
 - (a) Save the `UARTi.EFR_REG[4]` ENHANCED_EN value.
 - (b) Set the `UARTi.EFR_REG[4]` ENHANCED_EN bit to 1.
4. Switch to register operational mode to access the `UARTi.IER_REG` register:
Set `UARTi.LCR_REG` to 0x0000.

5. Clear the `UARTi.IER_REG` (`UARTi.IER_REG[4]` SLEEP_MODE bit to 0 to change `UARTi.DLL_REG` and `UARTi.DLH_REG`). Set `UARTi.IER_REG` to 0x0000.
6. Switch to register configuration mode B to access the `UARTi.DLL_REG` and `UARTi.DLH_REG` registers:
Set `UARTi.LCR_REG` to 0x00BF.
7. Load the new divisor value:
Set the `UARTi.DLL_REG[7:0]` CLOCK_LSB and `UARTi.DLH_REG[5:0]` CLOCK_MSB fields to the desired value.
8. Switch to register operational mode to access the `UARTi.IER_REG` register:
Set `UARTi.LCR_REG` to 0x0000.
9. Load the new interrupt configuration.(0: Disable the interrupt/1: Enable the interrupt):
Set the following bits to the desired values:
 - `UARTi.IER_REG[7]` CTS_IT
 - `UARTi.IER_REG[6]` RTS_IT
 - `UARTi.IER_REG[5]` XOFF_IT
 - `UARTi.IER_REG[4]` SLEEP_MODE
 - `UARTi.IER_REG[3]` MODEM_STS_IT
 - `UARTi.IER_REG[2]` LINE_STS_IT
 - `UARTi.IER_REG[1]` THR_IT
 - `UARTi.IER_REG[0]` RHR_IT
10. Switch to register configuration mode B to access the `UARTi.EFR_REG` register:
Set `UARTi.LCR_REG` to 0x00BF.
11. Restore the `UARTi.EFR_REG[4]` ENHANCED_EN value saved in Step 3a.
12. Load the new protocol formatting (parity, stop bit, char length) and switch to register operational mode:
Set `UARTi.LCR_REG[7]` DIV_EN to 0.
Set `UARTi.LCR_REG[6]` BREAK_EN to 0.
Set the following bits to the desired values:
 - `UARTi.LCR_REG[5]` PARITY_TYPE_2
 - `UARTi.LCR_REG[4]` PARITY_TYPE_1
 - `UARTi.LCR_REG[3]` PARITY_EN
 - `UARTi.LCR_REG[2]` NB_STOP
 - `UARTi.LCR_REG[1:0]` CHAR_LENGTH
13. Load the new UART mode:
Set `UARTi.MDR1_REG[2:0]` MODE_SELECT to the desired value.

See [Section 19.4.4.1.2, Choosing the Appropriate Divisor Value](#), to choose the following values:

- `UARTi.DLL_REG[7:0]` CLOCK_LSB
- `UARTi.DLH_REG[5:0]` CLOCK_MSB
- `UARTi.MDR1_REG[2:0]` MODE_SELECT

See [Section 19.4.4.1.3.1, Frame Formatting](#), to choose the following values:

- `UARTi.LCR_REG[5]` PARITY_TYPE_2
- `UARTi.LCR_REG[4]` PARITY_TYPE_1
- `UARTi.LCR_REG[3]` PARITY_EN
- `UARTi.LCR_REG[2]` NB_STOP
- `UARTi.LCR_REG[1:0]` CHAR_LENGTH

19.5.1.2 Hardware and Software Flow Control Configuration

This section outlines the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

NOTE: Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 19.4.3.1, Register Access Modes](#).

19.5.1.2.1 Hardware Flow Control Configuration

To enable and configure hardware flow control, perform the following procedure:

1. Switch to register configuration mode A to access the `UARTi.MCR_REG` register:
 - (a) Save the current `UARTi.LCR_REG`.
 - (b) Set `UARTi.LCR_REG` to 0x0080.
2. Enable register submode TCR_TLR to access `UARTi.TCR_REG` (part 1 of 2):
 - (a) Save the `UARTi.MCR_REG[6]` TCR_TLR value.
 - (b) Set `UARTi.MCR_REG[6]` TCR_TLR = 1.
3. Switch to register configuration mode B to access the `UARTi.EFR_REG` register:
Set `UARTi.LCR_REG` to 0x00BF.
4. Enable register submode TCR_TLR to access the `UARTi.TCR_REG` register (part 2 of 2):
 - (a) Save the `UARTi.EFR_REG[4]` ENHANCED_EN value.
 - (b) Set the `UARTi.EFR_REG[4]` ENHANCED_EN bit to 1.
5. Load the new start and halt trigger values for hardware flow control:
Set the following bits to the desired values:
 - `UARTi.TCR_REG[7:4]` AUTO_RTS_START
 - `UARTi.TCR_REG[3:0]` AUTO_RTS_HALT
6. Enable or disable receive and transmit hardware flow control mode and restore the `UARTi.EFR_REG[4]` ENHANCED_EN value saved in Step 4a.
Set the following bits to the desired values:
 - `UARTi.EFR_REG[7]` AUTO_CTS_EN (0: Disable/1: Enable)
 - `UARTi.EFR_REG[6]` AUTO_RTS_EN (0: Disable/1: Enable)Restore `UARTi.EFR_REG[4]` ENHANCED_EN to the saved value.
7. Switch to register configuration mode A to access `UARTi.MCR_REG`:
Set `UARTi.LCR_REG` to 0x0080.
8. Restore the `UARTi.MCR_REG[6]` TCR_TLR value saved in Step 2a.
9. Restore the `UARTi.LCR_REG` value saved in Step 1a.

See [Section 19.4.4.1.3.2, Hardware Flow Control](#), to choose the following values:

- `UARTi.EFR_REG[7]` AUTO_CTS_EN
- `UARTi.EFR_REG[6]` AUTO_RTS_EN
- `UARTi.TCR_REG[7:4]` AUTO_RTS_START
- `UARTi.TCR_REG[3:0]` AUTO_RTS_HALT

19.5.1.2.2 Software Flow Control Configuration

To enable and configure software flow control, perform the following procedure:

1. Switch to register configuration mode B to access the `UARTi.EFR_REG` register.

- (a) Save the current UARTi.[LCR_REG](#).
- (b) Set UARTi.[LCR_REG](#) to 0x00BF.
2. Enable register submode XOFF to access the UARTi.[XOFF1_REG](#) and UARTi.[XOFF2_REG](#) registers:
- (a) Save the UARTi.[EFR_REG\[4\]](#) ENHANCED_EN value.
- (b) Set the UARTi.[EFR_REG\[4\]](#) ENHANCED_EN bit to 0.
3. Load the new software flow control characters:
- Set the following bits to the desired values:
- UARTi.[XON1_ADDR1_REG\[7:0\]](#) XON_WORD1
 - UARTi.[XON2_ADDR2_REG\[7:0\]](#) XON_WORD2
 - UARTi.[XOFF1_REG\[7:0\]](#) XOFF_WORD1
 - UARTi.[XOFF2_REG\[7:0\]](#) XOFF_WORD2
4. Enable access to UARTi.[MCR_REG\[7:5\]](#) and enable register submode TCR_TLR to access UARTi.[TCR_REG](#) (part 1 of 2):
- Set the UARTi.[EFR_REG\[4\]](#) ENHANCED_EN bit to 1.
5. Switch to register configuration mode A to access the UARTi.[MCR_REG](#) register:
- Set UARTi.[LCR_REG](#) to 0x0080.
6. Enable register submode TCR_TLR to access UARTi.[TCR_REG](#) (part 2 of 2) and enable or disable XON any function:
- (a) Save the UARTi.[MCR_REG\[6\]](#) TCR_TLR value.
- (b) Set the UARTi.[MCR_REG\[6\]](#) TCR_TLR to 1.
- Set UARTi.[MCR_REG\[5\]](#) XON_EN to the desired value (0: Disable/1: Enable).
7. Switch to register configuration mode B to access the UARTi.[EFR_REG](#) register:
- Set UARTi.[LCR_REG](#) to 0x00BF.
8. Load the new start and halt trigger values for software flow control:
- Set the following bits to the desired values:
- UARTi.[TCR_REG\[7:4\]](#) AUTO_RTS_START
 - UARTi.[TCR_REG\[3:0\]](#) AUTO_RTS_HALT
9. Enable or disable special char function and load the new software flow control mode and restore the UARTi.[EFR_REG\[4\]](#) ENHANCED_EN value saved in Step 2a:
- Set the following bits to the desired values:
- UARTi.[EFR_REG\[5\]](#) SPEC_CHAR (0: Disable/1: Enable)
 - UARTi.[EFR_REG\[3:0\]](#) SW_FLOW_CONTROL
- Restore UARTi.[EFR_REG\[4\]](#) ENHANCED_EN to the saved value.
10. Switch to register configuration mode A to access the UARTi.[MCR_REG](#) register:
- Set UARTi.[LCR_REG](#) to 0x0080.
11. Restore the UARTi.[MCR_REG\[6\]](#) TCR_TLR value saved in Step 6a.
12. Restore the UARTi.[LCR_REG](#) value saved in Step 1a.
- See [Section 19.4.4.1.3.3, Software Flow Control](#), to choose the following values:
- UARTi.[EFR_REG\[5\]](#) SPEC_CHAR
 - UARTi.[EFR_REG\[3:0\]](#) SW_FLOW_CONTROL
 - UARTi.[TCR_REG\[7:4\]](#) AUTO_RTS_START
 - UARTi.[TCR_REG\[3:0\]](#) AUTO_RTS_HALT
 - UARTi.[XON1_ADDR1_REG\[7:0\]](#) XON_WORD1
 - UARTi.[XON2_ADDR2_REG\[7:0\]](#) XON_WORD2
 - UARTi.[XOFF1_REG\[7:0\]](#) XOFF_WORD1
 - UARTi.[XOFF2_REG\[7:0\]](#) XOFF_WORD2

19.5.2 IrDA Programming Model (UART3 Only)

19.5.2.1 SIR Mode

19.5.2.1.1 Receive

The following programming model explains how to program the module to receive IrDA frame with parity forced to 1, baud rate = 112.5 Kbs, FIFOs disable, 2 stop bits, 8-bit word length.

1. **Disable UART before accessing `UARTi.DLL_REG` and `UARTi.DLH_REG`:**
Set `UARTi.MDR1_REG[2:0]` MODE_SELECT to 0x7.
2. **Grant access to `DLL_REG` and `DLH_REG` (`LCR_REG[7]` DIV_EN = 0x1)**
`UART3.LCR_REG` = 0x80 (Note: Data format is unaffected by the use and settings of the `UART3.LCR_REG` register in IrDA mode.)
3. **Load the new baud rate (115.2Kbs)**
`UART3.DLL_REG` = 0x1A
`UART3.DLH_REG` = 0x00
4. **Set SIR Mode**
`UART3.MDR1_REG[2:0]` MODE_SELECT = 0x1
5. **Disable access to `DLL_REG` and `DLH_REG` and switch to register operational mode**
`UART3.LCR_REG` = 0x00.
6. **Optional: Enable RHR interrupt**
`UART3.IER_REG[0]` RHR_IT = 0x1

19.5.2.1.2 Transmit

The following programming model explains how to program the module to transmit IrDA 6 bytes frame with no parity, baud rate = 112.5Kbs, FIFOs disable, 3/16 encoding, 2 stop bits, 7 bits word length

1. **Disable UART before accessing `UARTi.DLL_REG` and `UARTi.DLH_REG`:**
Set `MDR1_REG[2:0]` MODE_SELECT = 0x7).
2. **Grant access to `EFR_REG`**
`UART3.LCR_REG` = 0xBF
3. **Enable the enhanced features (`EFR_REG[4]` ENAHNCED_EN = 0x1)**
`UART3.EFR_REG` = 0x10.
4. **Grant access to `DLL_REG` and `DLH_REG` (`LCR_REG[7]` DIV_EN = 0x1)**
`UART3.LCR_REG` = 0x80 (Note: Data format is unaffected by the use and settings of the `UART3.LCR_REG` register in IrDA mode.)
5. **Load the new baud rate (115.2Kbs)**
`UART3.DLL_REG` = 0x1A
`UART3.DLH_REG` = 0x00
6. **Set SIR Mode (`MDR1_REG[2:0]` MODE_SELECT = 0x1)**
`UART3.MDR1_REG` = 0x01.
7. **Disable access to `DLL_REG` and `DLH_REG` and switch to register operational mode**
`UART3.LCR_REG`
`UART3.LCR_REG` = 0x00.
8. **Force DTR output to active**
`UART3.MCR_REG[0]` DTR = 0x1
9. **Optional: Enable THR interrupt**
`UART3.IER_REG[1]` THR_IT = 0x1
10. **Set transmit frame length to 6 bytes**
`UART3.TXFLL_REG` = 0x06
11. **Set 7 starts of frame transmission**
`UART3.EBLR_REG` = 0x08
12. **Optional: Set SIR pulse width to be 1.6 μ s**
`UART3.ACREG_REG[7]` PULSE_TYPE = 0x1

13. Load `THR_REG` with the desired data to be transmitted

19.5.2.2 MIR Mode

19.5.2.2.1 Receive

The following programming model explains how to program the module to receive IrDA frame with no parity, baud rate = 1.152Mbs, FIFOs disable

1. **Disable UART before accessing `UARTi.DLL_REG` and `UARTi.DLH_REG`**
Set `UARTi.MDR1_REG[2:0]` MODE_SELECT to 0x7.
2. **Grant access to `DLL_REG` and `DLH_REG` (`LCR_REG[7] DIV_EN = 0x1`)**
`UART3.LCR_REG` = 0x80 (Note: Data format is unaffected by the use and settings of the `UART3.LCR_REG` register in IrDA mode).
3. **Load the new baud rate (1.152 Mbs)**
`UART3.DLL_REG` = 0x01
`UART3.DLH_REG` = 0x00.
4. **Set MIR Mode**
`UART3.MDR1_REG[2:0]` MODE_SELECT = 0x4
5. **Disable access to `DLL_REG` and `DLH_REG` and switch to register operational mode**
`UART3.LCR_REG` = 0x00.
6. **Force DTR output to active (`MCR_REG[0] DTR = 0x1`)**
Force RTS output to active (`MCR_REG[1] RTS = 0x1`)
`UART3.MCR_REG` = 0x3
7. **Optional: Enable RHR interrupt**
`UART3.IER_REG[0]` RHR_IT = 0x1

19.5.2.2.2 Transmit

The following programming model explains how to program the module to transmit IrDA 60 bytes frame with no parity, baud rate = 1.152Mbs, FIFOs disable

1. **Disable UART before accessing `UARTi.DLL_REG` and `UARTi.DLH_REG`:**
Set `UARTi.MDR1_REG[2:0]` MODE_SELECT to 0x7.
2. **Grant access to `DLL_REG` and `DLH_REG` (`LCR_REG[7] DIV_EN = 0x1`)**
`UART3.LCR_REG` = 0x80 (Note: Data format is unaffected by the use and settings of the `UART3.LCR_REG` register in IrDA mode.)
3. **Load the new baud rate (1.152 Mbs)**
`UART3.DLL_REG` = 0x01
`UART3.DLH_REG` = 0x00
4. **Set MIR Mode**
`UART3.MDR1_REG[2:0]` MODE_SELECT = 0x4.
5. **Disable access to `DLL_REG` and `DLH_REG` and switch to register operational mode:**
`UART3.LCR_REG` = 0x00.
6. **Force DTR output to active**
`UART3.MCR_REG[0]` DTR = 0x1
7. **Optional: Enable THR interrupt**
`UART3.IER_REG[1]` THR_IT = 0x1
8. **Set frame length to 60 bytes**
`UART3.TXFLL_REG` = 0x3C
9. **Optional: Transmit 8 additional starts of frame (MIR mode requires 2 starts anyway)**
`UART3.EBLR_REG` = 0x08
10. **SIP will be send at the end of transmission**
`UART3.ACREG_REG[3]` = 0x1
11. **Load `THR_REG` with the desired data to be transmitted**

19.5.2.2.3 FIR Mode

19.5.2.2.3.1 Receive

The following programming model explains how to program the module to receive IrDA frame with no parity, baud rate = 4M bits/s, FIFOs enable, 8-bit word length.

1. Disable UART before accessing **UART_i.DLL_REG** and **UART_i.DLH_REG**: Set **UART_i.MDR1_REG[2:0]** **MODE_SELECT** to 0x7.
2. Grant access to **DLL_REG** and **DLH_REG** (**LCR_REG[7]** DIV_EN = 0x1 **UART3.LCR_REG** = 0x80
(Note: Data format is unaffected by the use and settings of the **UART3.LCR_REG** register in IrDA mode.)
3. FIFO clear and enable **FCR_REG** = 0x7 (Tx/Rx FIFO trigger : **FCR_REG[7:6]** & **FCR_REG[5:4]**) **LCR_REG[7]**=0.
4. Set FIR Mode **UART3.MDR1_REG[2:0]** **MODE_SELECT** = 0x5.
5. Set frame length **RXFLL_REG** = 0xA (Data + CRC + STO).
6. Disable access to **DLL_REG** and **DLH_REG** and switch to register operational mode **UART3.LCR_REG[7]** DIV_EN = 0x0.
7. Optional: Enable RHR interrupt **UART3.IER_REG[0]** RHR_IT = 0x1.

19.5.2.2.3.2 Transmit

The following programming model explains how to program the module to transmit IrDA 4 bytes frame with no parity, baud rate = 4M bits/s, FIFOs enable, 8-bit word length.

1. Disable UART before accessing **UART_i.DLL_REG** and **UART_i.DLH_REG**: Set **MDR1_REG[2:0]** **MODE_SELECT** = 0x7).
2. Grant access to **EFR_REG** **UART3.LCR_REG** = 0xBF.
3. Enable the enhanced features (**EFR_REG[4]** ENAHNCED_EN = 0x1) **UART3.EFR_REG** = 0x10.
4. FIFO clear and enable **FCR_REG** = 0x7 (Tx/Rx FIFO trigger: **FCR_REG[7:6]** and **FCR_REG[5:4]**) **LCR_REG[7]** = 0
5. Set FIR mode and enable auto-SIP mode **MDR1_REG** = 0x45.
6. Set Frame Length **TXFLL_REG** = 0x4 **TXFLH_REG** = 0x0 **RXFLL_REG** = 0xA (Data + CRC + STO) **RXFLH_REG** = 0x0.
7. Force DTR output to active **UART3.MCR_REG[0]** DTR = 0x1.
8. Optional: Enable THR interrupt **UART3.IER_REG[1]** THR_IT = 0x1.
9. Load **THR_REG** with the desired data to be transmitted.

19.6 UART/IrDA/CIR Register Manual

19.6.1 UART/IrDA/CIR Instance Summary

Table 19-38 shows the base address and address space for the UART/IrDA/CIR module instances.

Table 19-38. UART/IrDA/CIR Instance Summary

Module Name	Base Address	Size
UART1 ⁽¹⁾	0x4806 A000	4KB
UART2 ⁽¹⁾	0x4806 C000	4KB
UART3 ⁽²⁾	0x4902 0000	4KB
UART4 ⁽¹⁾	0x4904 2000	4KB

⁽¹⁾ UART only

⁽²⁾ UART, IrDA and CIR

CAUTION

The UART_THR register is limited to 8-bit data accesses; 16- and 32-bit data accesses are not allowed and can corrupt the register content.

19.6.2 UART/IrDA/CIR Register Summary

NOTE: UART/IrDA/CIR registers access depends on access mode and submode. For more information, see [Section 19.4.3.1, Register Access Modes](#).

Table 19-39. UART/IrDA/CIR Register Summary Part 1

Register Name	Type	Register Width (Bits)	Address Offset	UART1 Physical Address	UART2 Physical Address	UART3 Physical Address

19.6.3 UART/IrDA/CIR Register Description

Table 19-41. DLL_REG

Address Offset	0x000
Physical Address	See Table 19-39 to Table 19-40
Description	Divisor latches low This register, with DLH_REG , stores the 14-bit divisor for generation of the baud clock in the baud rate generator. DLH_REG stores the most-significant part of the divisor. DLL_REG stores the least-significant part of the divisor.
Note:	DLL_REG and DLH_REG can be written to only before sleep mode is enabled (before IER_REG[4] is set).
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								CLOCK_LSB							

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Read returns 0.	R	0x000000
7:0	CLOCK_LSB	Stores the 8-bit LSB divisor value	RW	0x00

Table 19-43. RHR_REG

Address Offset	0x000																																																								
Physical Address	See Table 19-39 to Table 19-40																																																								
Description	Receive holding register																																																								
<p>The receiver section consists of the receiver holding register (RHR_REG) and the receiver shift register. The RHR_REG is actually a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR_REG. If the FIFO is disabled, location zero of the FIFO is used to store the single data character.</p> <p>RHR_REG must be read only after it is verified that the receive FIFO is not empty; this is done by reading the LSR_REG[0] RX_FIFO_E bit.</p> <p>Note: If an overflow occurs the data in the RHR_REG is not overwritten.</p>																																																									
Type	R

Table 19-51. FCR_REG

Address Offset	0x008
Physical Address	See Table 19-39 to Table 19-40
Description	FIFO control register
Type	W

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Write has no functional effect.	W	0x000000
7:6	RX_FIFO_TRIG	Sets the trigger level for the RX FIFO: If SCR_REG[7] = 0 and TLR_REG[7:4] ≠ 0000 , RX_FIFO_TRIG is not considered. If SCR_REG[7] = 1 , RX_FIFO_TRIG is 2 LSB of the trigger level (1 to 63 on 6 bits) with a granularity of 1. If SCR_REG[7] = 0 and TLR_REG[7:4] = 0000 : 0x0: 8 characters 0x1: 16 characters 0x2: 56 characters 0x3: 60 characters	W	0x0
5:4	TX_FIFO_TRIG	Can be written only if EFR_REG[4] = 1 . Sets the trigger level for the TX FIFO. If SCR_REG[6] = 0 and TLR_REG[3:0] ≠ 0000 , TX_FIFO_TRIG is not considered. If SCR_REG[6] = 1 , RX_FIFO_TRIG is 2 LSB of the trigger level (1 to 63 on 6 bits) with a granularity of 1. If SCR_REG[6] = 0 and TLR_REG[3:0] = 0000 : 0x0: 8 characters 0x1: 16 characters 0x2: 32 characters 0x3: 56 characters	W	0x0
3	DMA_MODE	Can be changed only when the baud clock is not running (DLL_REG and DLH_REG set to 0). This register is considered if SCR_REG[0] = 0 . 0x0: DMA_MODE 0 (No DMA) 0x1: DMA_MODE 1 (UART_NDMA_REQ[0] in TX, UART_NDMA_REQ[1] in RX)	W	0
2	TX_FIFO_CLEAR	Clears the TX FIFO 0x0: No change 0x1: Clears the transmit FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.	W	0
1	RX_FIFO_CLEAR	Clears the RX FIFO. 0x0: No change 0x1: Clears the receive FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.	W	0
0	FIFO_EN	Can be changed only when the baud clock is not running (DLL_REG and DLH_REG set to 0). 0x0: Disables the transmit and receive FIFOs. The transmit and receive holding registers are 1-byte FIFOs. 0x1: Enables the transmit and receive FIFOs. The transmit and receive holding registers are 64-byte FIFOs.	W	0

Table 19-55. EFR_REG

Address Offset	0x008
Physical Address	See Table 19-39 to Table 19-40
Description	Enhanced feature register
	This register enables or disables enhanced features. Most enhanced functions apply only to UART modes, but EFR_REG[4] enables write accesses to FCR_REG[5:4] , the TX trigger level, which is also used in IrDA modes.
Type	RW

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Read returns 0.	R	0x000000
7	AUTO_CTS_EN	Auto-CTS enable bit (UART mode only) 0x0: Normal operation	RW	0

Bits	Field Name	Description	Type	Reset
		0x1: Auto-CTS flow control is enabled; transmission is halted when the nCTS pin is high (inactive).		
6	AUTO_RTS_EN	Auto-RTS enable bit (UART mode only) 0x0: Normal operation 0x1: Auto-RTS flow control is enabled; nRTS pin goes high (inactive) when the receiver FIFO HALT trigger level, TCR_REG[3:0] , is reached and goes low (active) when the receiver FIFO RESTORE transmission trigger level is reached.	RW	0
5	SPEC_CHAR	(UART mode only) Special character detect 0x0: Normal operation 0x1: Special character detect enable. Received data is compared with XOFF2 data. If a match occurs, the received data is transferred to RX FIFO and IIR_REG bit 4 is set to 1 to indicate that a special character was detected.	RW	0
4	ENHANCED_EN	Enhanced functions write enable bit 0x0: Disables writing to IER_REG bits [7:4], FCR_REG bits [5:4], and MCR_REG bits [7:5] 0x1: Enables writing to IER_REG bits [7:4], FCR_REG bits [5:4], and MCR_REG bits [7:5]	RW	0
3:0	SW_FLOW_CONTROL	Combinations of software flow control can be selected by programming bit [3:0]. See Table 19-32 . In IrDA mode, bits [1:0] select IR address to check. See Section 19.2.5.2.1.7, IR Address Checking .	RW	0x0

Table 19-57. LCR_REG

Address Offset	0x00C
Physical Address	See Table 19-39 to Table 19-40
Description	Line control register
	LCR_REG[6:0] define parameters of the transmission and reception for UART mode. LCR_REG[7] is used to put the module in operational mode or Configuration_Mode_A/B.

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Read returns 0	R	0x000000
7	DIV_EN		RW	0
		0x0: Operational mode 0x1: Divisor latch enable; put the module in Configuration_Mode_A/B. Allows access to DLL_REG , DLH_REG , and other registers (see Section 19.6.2, UART/IrDA/CIR Register Mapping Summary). Configuration_Mode_B: LCR_REG[7:0] = 0xBF Else, Configuration_Mode_A		
6	BREAK_EN	Break control bit. UART mode only. Note: When LCR_REG[6] is set to 1, the TX line is forced to 0 and remains in this state as long as LCR_REG[6] = 1 . 0x0: Normal operating condition 0x1: Forces the transmitter output to go low to alert the communication terminal. TX line is forced to 0 and remains in this state while BREAK_EN = 1.	RW	0
5	PARITY_TYPE2	Selects the forced parity format (if LCR_REG[3] = 1). UART mode only. If LCR_REG[5] = 1 and LCR_REG[4] = 0 , the parity bit is forced to 1 in the transmitted and received data. If LCR_REG[5] = 1 and LCR_REG[4] = 1 , the parity bit is forced to 0 in the transmitted and received data.	RW	0
4	PARITY_TYPE1	UART mode only 0x0: Odd parity is generated (if LCR_REG[3] = 1). 0x1: Even parity is generated (if LCR_REG[3] = 1).	RW	0
3	PARITY_EN	UART mode only 0x0: No parity 0x1: A parity bit is generated during transmission, and the receiver checks for received parity.	RW	0
2	NB_STOP	Specifies the number of stop bits. UART mode only. 0x0: 1 stop bit (word length = 5, 6, 7, 8) 0x1: 1.5 stop bits (word length = 5)1 - 2 stop bits (word length = 6, 7, 8)	RW	0
1:0	CHAR_LENGTH	Specifies the word length to be transmitted or received. UART mode only. 0x0: 5 bits 0x1: 6 bits	RW	0x0

Bits	Field Name	Description	Type	Reset
		0x2: 7 bits		
		0x3: 8 bits

Table 19-59. MCR_REG

Address Offset	0x010
Physical Address	See Table 19-39 to Table 19-40
Description	Modem control register MCR_REG[3:0] controls the interface with the modem, data set, or peripheral device that is emulating the modem.
Type	RW

Bits	Field Name	Description	Type	Reset
31:7	Reserved	Read returns 0.	R	0x0000000
6	TCR_TLR	Can be written only when EFR_REG[4] ENHANCED_EN = 1 0x0: No action 0x1: Enables access to the TCR_REG and TLR_REG registers	RW	0
5	XON_EN	Can be written only when EFR_REG[4] ENHANCED_EN = 1 0x0: Disable XON any function 0x1: Enable XON any function	RW	0
4	LOOPBACK_EN	 0x0: Normal operating mode 0x1: Enable local loopback mode (internal).	RW	0

Bits	Field Name	Description	Type	Reset
		In this mode, the MCR_REG[3:0] signals are looped back into MSR_REG[7:4] . The transmit output is looped back to the receive input internally.		
3	CD_STS_CH		RW	0
		0x0: In loopback, forces nDCD input high and IRQ outputs to INACTIVE state. 0x1: In loopback, forces nDCD input low and IRQ outputs to INACTIVE state.		
2	RI_STS_CH		RW	0
		0x0: In loopback, forces nRI input inactive (high). 0x1: In loopback, forces nRI input active (low).		
1	RTS	In loop back, controls MSR_REG[4] . If auto-RTS is enabled, the nRTS output is controlled by hardware flow control.	RW	0
		0x0: Force nRTS output to inactive (high). 0x1: Force nRTS output to active (low).		
0	DTR	0: Force DTR output (used in loop back mode) to inactive (high) 1: Force DTR output (used in loop back mode) to active (low)	RW	0

Table 19-81. MDR2_REG

Address Offset	0x024
Physical Address	See Table 19-39 to Table 19-40
Description	Mode definition register 2 IR-IrDA and IR-CIR modes only MDR2_REG[0] describes the status of the interrupt in IIR_REG[5] . The IRTX_UNDERRUN bit must be read after an IIR_REG[5] TX_STATUS_IT interrupt occurs. The bits [2:1] of this register set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in MDR1_REG[2:0] .
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																									SET_TXIR_ALT	IRR_XINVERT	CIR_PULSE_MODE	UART_PULSE	STS_FIFO_TRIG	IRTX_UNDERRUN	

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Read returns 0x00.	R	0x00
7	SET_TXIR_ALT	Provide alternate functionnality for MDR1[4] (SET_TXIR) 0x0: Normal mode. 0x1: Alternate mode for SET_TXIR.	RW	0
6	IRR_XINVERT	Only for IR mode (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes. 0x0: Inversion is performed. 0x1: No inversion is performed.	RW	0
5:4	CIR_PULSE_MODE	CIR pulse modulation definition. Defines high level of the pulse width associated with a digit: 0x0: Pulse width of 3 from 12 cycles 0x1: Pulse width of 4 from 12 cycles 0x2: Pulse width of 5 from 12 cycles 0x3: Pulse width of 6 from 12 cycles	RW	0x00
3	UART_PULSE	UART mode only. Used to allow pulse shaping in UART mode. 0x0: Normal UART mode 0x1: UART mode with pulse shaping	RW	0
2:1	STS_FIFO_TRIG	Only for IR-IrDA mode Frame status FIFO threshold select: 0x0: 1 entry 0x1: 4 entries 0x2: 7 entries 0x3: 8 entries	RW	0x00
0	IRTX_UNDERRUN	IrDA transmission status interrupt. When the IIR_REG[5] interrupt occurs, the meaning of the interrupt is: 0x0: The last bit of the frame was transmitted successfully without error. 0x1: An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the RESUME_REG register is read.	R	0

Address Offset	0x038																										
Physical Address	See Table 19-39 to Table 19-40																										
Description	UART autobauding status register UART autobauding mode only This status register returns the speed, the number of bits by characters, and the type of parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition.

Table 19-103. ACREG_REG

Address Offset	0x03C
Physical Address	See Table 19-39 to Table 19-40
Description	Auxiliary control register
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Read returns 0.	R	0x00
7	PULSE_TYPE	SIR pulse-width select: 0x0: 3/16 of baud-rate pulse width 0x1: 1.6 µs	RW	0
6	SD_MOD	Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0x0: SD pin is set to high. 0x1: SD pin is set to low.	RW	0
5	DIS_IR_RX	0x0: Normal operation (RX input automatically disabled during transmit, but enabled outside of transmit operation). 0x1: Disables RX input (permanent state; independent of transmit)	RW	0
4	DIS_TX_UNDERRUN	0x0: Long stop bits cannot be transmitted. TX underrun is enabled. 0x1: Long stop bits can be transmitted. TX underrun is disabled.	RW	0

Bits	Field Name	Description	Type	Reset
3	SEND_SIP	MIR/FIR modes only. Send serial infrared interaction pulse (SIP). If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is automatically cleared at the end of the SIP transmission. 0x0: No action 0x1: Send SIP pulse.	RW	0
2	SCTX_EN	Store and control TX start. When MDR1_REG [5] = 1 and the MPU writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.	RW	0
1	ABORT_EN	Frame abort. The MPU can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame.	RW	0
0	EOT_EN	EOT (end-of-transmission) bit. The MPU writes 1 to this bit just before it writes the last byte to the TX FIFO in the set-EOT bit frame-closing method. This bit is automatically cleared when the MPU writes to the THR_REG (TX FIFO).	RW	0

Table 19-109. EBLR_REG

Address Offset	0x048
Physical Address	See Table 19-39 to Table 19-40
Description	BOF length register. IR-IrDA mode only In IR-IrDA SIR operation, this register specifies the number of BOF + xBOFs to transmit. Value set into this register must consider the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with N XBOF, this register must be set to N + 1. Furthermore, the value 0 sends 1 BOF plus 255 XBOF. In IR-IrDA MIR mode, this register specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags).
Type	RW

Description	Carrier frequency prescaler
Type	RW
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
RESERVED	CFPS

Bits	Field Name	Description	Type	Reset																								
31:8	Reserved	Read returns 0.	R	0x000000																								
7:0	CFPS	Because the consumer IR works at modulation rates of 30-56.8 kHz, the 48-MHz clock must be prescaled before the clock can drive the IR logic. This register sets the divisor rate to give a range to accommodate remote-control requirements in BAUD multiples of 12x. The value of the CFPS at reset is 0105 (decimal), which equates to a 38.1-kHz output from starting conditions. The 48-MHz carrier is prescaled by the CFPS, which is then divided by the 12x BAUD multiple. Example: <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>Target Freq (kHz)</th> <th>CFPS (decimal)</th> <th>Actual Freq(kHz)</th> </tr> </thead> <tbody> <tr> <td>30</td> <td>133</td> <td>30.08</td> </tr> <tr> <td>32.75</td> <td>122</td> <td>32.79</td> </tr> <tr> <td>36</td> <td>111</td> <td>36.04</td> </tr> <tr> <td>36.7</td> <td>109</td> <td>36.69</td> </tr> <tr> <td>38</td> <td>105</td> <td>38.1</td> </tr> <tr> <td>40</td> <td>100</td> <td>40</td> </tr> <tr> <td>56.8</td> <td>70</td> <td>57.14</td> </tr> </tbody> </table> CFPS = 0 is not supported.	Target Freq (kHz)	CFPS (decimal)	Actual Freq(kHz)	30	133	30.08	32.75	122	32.79	36	111	36.04	36.7	109	36.69	38	105	38.1	40	100	40	56.8	70	57.14	RW	0x69

Multichannel SPI

This chapter describes the four multichannel serial port interface (McSPI) modules.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
20.1 McSPI Overview	2998
20.2 McSPI Environment	3001
20.3 McSPI Functional Interface	3004
20.4 McSPI Integration	3009
20.5 McSPI Functional Description	3013
20.6 McSPI Basic Programming Model	3034
20.7 McSPI Register Manual	3055

20.1 McSPI Overview

The multichannel serial port interface (McSPI) is a master/slave synchronous serial bus. There are four separate McSPI modules (SPI1, SPI2, SPI3, and SPI4) in the device (see [Figure 20-1](#)). The McSPI modules differ as follows: SPI1 supports up to four peripherals, SPI2 and SPI3 support up to two peripherals, and SPI4 supports only one peripheral.

NOTE: In this chapter, $m=[1,4]$ represents the module instance and x represents the channel in signal and register naming. There are four McSPI instances. Each module instance has different channel numbers:

- SPI1: 4 channels (if $m=1$, $x=4$)
 - SPI2: 2 channels (if $m=2$, $x=2$)
 - SPI3: 2 channels (if $m=3$, $x=2$)
 - SPI4: 1 channel (if $m=4$, $x=1$)
-

Figure 20-1. Multichannel Modules SPI1, SPI2, SPI3, and SPI4

The McSPI instances include the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths ranging from 4 bits to 32 bits
- Up to four master channels or single channel in slave mode
- Master multichannel mode:
 - Full duplex/half duplex
 - Transmit-only/receive-only/transmit-and-receive modes

- Flexible I/O port controls per channel
- Two direct memory access (DMA) requests (read/write) per channel
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Support start-bit write command
- Support start-bit pause and break sequence
- 64 bytes built-in FIFO available for a single channel
- Force CS mode for continuous transfers

20.2 McSPI Environment

Figure 20-2 shows a simplified overview of a typical application system using the McSPI. This example is based on a TFS chipset (TFS6040-0098), including a 2.2-inch color-active matrix thin-film transistor (TFT) liquid crystal display (LCD) with a light-emitting diode (LED) front light, a four-wire resistive touch-screen panel, and LCD controllers. This chipset is associated with the TSC2005 or TSC2006 touch-screen controller, powered by a power-management unit, and driven by the device. The McSPI device interface is set to master mode; the touch-screen McSPI controller interface operates in slave mode.

Figure 20-2. Typical Application Using the McSPI

mcspi_GN3-001

Figure 20-3 through Figure 20-8 show master mode and slave mode configurations. Each mode can be wired on a single-duplex or full-duplex configuration.

20.2.1 SPI Interface in Master Mode

Figure 20-3 shows a case in master mode (full-duplex) where the McSPI module is connected with two slave devices.

Figure 20-3. McSPI Master Mode (Full-Duplex)

NOTE: In this case $m=[1,3]$.

Figure 20-4 shows the master single mode, which can also be configured in receive-only mode.

Figure 20-4. McSPI Master Single Mode (Receive-Only)

20.2.2 SPI Interface in Slave Mode

Figure 20-5 shows a case in slave mode (full-duplex).

NOTE: Only channel 0 can be configured as slave, and only `spim_cs0` can be used as a chip-enable in slave mode.

Figure 20-5. McSPI Slave Mode (Full Duplex)

20.3 McSPI Functional Interface

20.3.1 Basic McSPI Pins for Master Mode

Figure 20-7 shows all of the McSPI interface signals in master mode.

Figure 20-7. McSPI Interface Signals in Master Mode

mcsipi-006

Table 20-1 describes the McSPI I/O in master mode.

Table 20-1. McSPI I/O Description (Master Mode)

Signal Name	I/O	Description	Reset (1)
spim_clk	O	SPIm module serial clock ⁽²⁾	Unknown
spim_simo	O	SPIm module serial data master out (slave input, master output)	Unknown
spim_somi	I	SPIm module serial data master input (slave output, master input)	—
spim_csx	O	SPIm module chip-select x output	Low

(1) After reset, the SPI modules are in slave mode by default. This paragraph implies that the McSPI module is configured in slave mode. (See the MCSPI_MODULCTRL[2] MS bit in the module control register [MCSPI_MODULCTRL].)

(2) This output signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

20.3.2 Basic McSPI Pins for Slave Mode

Figure 20-8 shows all of the McSPI interface signals in slave mode.

Figure 20-8. McSPI Interface Signals in Slave Mode

mcsipi-007

Table 20-2 describes the McSPI I/O in slave mode.

Table 20-2. McSPI I/O Description (Slave Mode)

Signal Name	I/O	Description	Reset ⁽¹⁾
spim_clk	I	SPI module serial clock	Unknown
spim_simo	I	SPI module serial data master out (slave input, master output)	Unknown
spim_somi	O	SPI module serial data master input (slave output, master input)	-
spim_csx	I	SPI module chip-select x output	Low

⁽¹⁾ After reset, the SPI modules are in slave mode by default. This paragraph implies that the McSPI module is configured in slave mode. (See the MCSPI_MODULCTRL[2] MS bit in Module Control Register (MCSPI_MODULCTRL).)

20.3.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (spim_csx) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

McSPI offers the flexibility to modify the following parameters to adapt to the device features:

- Word length

McSPI supports any SPI word ranging from 4 bits to 32 bits long (SPI module. [MCSPI_CHxCONF\[11:7\]](#) WL field).

SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.

- SPI enable (spim_csx, for channel x of instance m)

The polarity of the SPI enable signals is programmable (SPI module. [MCSPI_CHxCONF\[6\]](#) EPOL bit). spim_csx signals can be active high or low.

The assertion of the spim_csx signals is programmable and can be manually or automatically asserted. The manual assertion mode is available in single master mode only. spim_csx can be kept active between words with the SPI module. [MCSPI_CHxCONF\[20\]](#) FORCE bit.

Two consecutive words for two different slave devices can go along with active spim_csx signals with different polarity (see the example in [Section 20.6, McSPI Basic Programming Model](#)).

- Programmable start-bit

In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting SPI module. [MCSPI_CHxCONF\[23\]](#) SBE bit to 1. The SPI module. [MCSPI_CHxCONF\[24\]](#) SBPOL bit defines the polarity of the start-bit.

- Programmable SPI clock

- Bit rate

In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the power, reset, and clock management [PRCM] module). [Table 20-3](#) gives the spim_clk bit rates obtained for data transfer when programming the clock divider (SPI module. [MCSPI_CHxCONF\[5:2\]](#) CLKD bit field).

Table 20-3. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz
2	24 MHz
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz

Table 20-3. SPI Master Clock Rates (continued)

Divider	Clock Rate
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192	~5.8 kHz
16384	~2.9 kHz
32768	~1.5 kHz

- Polarity and phase

The polarity (the SPIm.`MCSPI_CHxCONF[1]` POL bit) and the phase (the SPIm.`MCSPI_CHxCONF[0]` PHA bit) of the SPI serial clock (`spim_clk`) are configurable to offer four combinations. Software selects the right combination, depending on the device. See [Table 20-4](#) and [Figure 20-9](#).

Table 20-4. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Comments
0	0	Mode 0	<code>spim_clk</code> is active high and sampling occurs on the rising edge.
0	1	Mode 1	<code>spim_clk</code> is active high and sampling occurs on the falling edge.
1	0	Mode 2	<code>spim_clk</code> is active low and sampling occurs on the falling edge.
1	1	Mode 3	<code>spim_clk</code> is active low and sampling occurs on the rising edge.

Figure 20-9. Phase and Polarity Combinations

mcsipi-009

20.3.3.1 Transfer Format

In both master and slave modes, McSPI drives the data lines when `spim_csx` is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one half cycle of spim_clk after the spim_csx assertion.

Therefore, the first edge of the spim_clk line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next spim_clk edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

This process continues for a number of pulses on the spim_clk line defined by the SPI word length programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See [Figure 20-10](#).

Figure 20-10. Full-Duplex Transfer Format With PHA = 0

- Transmission in mode 1 and mode 3 (PHA = 1)

When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following spim_clk edge (one half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the spim_csx activation and the first spim_clk edge.

The received data bit is shifted into the shift register on the third spim_clk edge.

This process continues for a number of pulses on the spim_clk line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

NOTE: The minimum synchronization delay is one cycle of spim_clk, if the spim_clk frequency equals the SPIIm_FCLK (McSPIIm functional clock) frequency in master mode. The minimum synchronization delay is one-half cycle of spim_clk, if the spim_clk frequency is lower than the SPIIm_FCLK frequency in both master and slave modes.

- Transmission with a start-bit (SBE = 1)

When the SPIIm.MCSPI_CHxCONF[23] SBE bit = 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

[Figure 20-11](#) shows an example of a data transfer with an extra start-bit.

Figure 20-11. Extended SPI Transfer With a Start-Bit (SBE = 1)

mcsipi-010

20.4 McSPI Integration

20.4.1 McSPI Description

Figure 20-12 highlights the McSPI module integration in the device.

Figure 20-12. McSPI Integration

20.4.2 Clocking, Reset, and Power-Management Scheme

20.4.2.1 Clocking

Each McSPI module is clocked with an independent functional clock of 48 MHz from the PRCM module ($SPI_{m,FCLK}$ with $m = [1,4]$) and with an interface clock, $CORE_{L4_ICLK}$ (L4 interconnect):

- $SPI_{m,FCLK}$ is the McSPI module m functional clock and is used to clock the McSPI internal logic. The source of $SPI_{m,FCLK}$ is the PRCM $CORE_{48M_FCLK}$ output clock.
- $SPI_{m,ICLK}$ is the McSPI module m interface clock and is used to synchronize the McSPI L4 port to the L4 interconnect. All accesses from the interconnect are synchronous with $SPI_{m,ICLK}$. The source of $SPI_{m,ICLK}$ is the PRCM $CORE_{L4_ICLK}$ output clock.

From a global system power management perspective, when one or both of the McSPI clocks is not required, the McSPI module can be deactivated at the PRCM level in the corresponding registers.

Table 20-5 describes the McSPI module PRCM clock control bits.

Table 20-5. McSPI Clocks

McSPI Clock	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
SPI _m _FCLK	CORE_48M_FCLK	PRCM.CM_FCLKEN1_CORE.EN_MC SPI _m (with m=[1,4])	N/A
SPI _m _ICLK	CORE_L4_ICLK	PRCM.CM_ICLKEN1_CORE.EN_MCS Plm (with m=[1,4])	PRCM.CM_AUTOIDLE1_CORE.AUTO_M CSPI _m (with m=[1,4])

NOTE:

- The PRCM CORE_48M_FCLK output is gated at the PRCM level, assuming that all modules sharing it are disabled in the corresponding register. Disabling the McSPI module is a necessary but insufficient condition.
- The PRCM CORE_L4_ICLK output is gated at the PRCM level, assuming that all modules sharing it are disabled in the corresponding register. Disabling the McSPI module is a necessary but insufficient condition.
- The PRCM.CM_AUTOIDLE1_CORE bit is used to link/unlink the McSPI module from CORE_L4_ICLK-related clock domain transitions.

For more information about source clocks gating and domain transitions, see [Chapter 3, Power, Reset, and Clock Management](#). For more information on power saving management, see [Section 20.5.7](#).

20.4.2.2 Power Domain

The McSPI modules belong to the CORE power domain (see [Table 20-6](#)).

Table 20-6. Power Domain

Peripherals	Power Domain
McSPI modules	CORE power domain

20.4.2.3 Hardware Reset

As part of the CORE power domain, CORE_RST is issued by the PRCM module (for more information about the CORE power domain implementation and CORE_RST signal, see [Chapter 3, Power, Reset, and Clock Management](#)). The module is reset by hardware when an active-low reset signal is asserted. The hardware reset signal has a global reset effect on the module. All configuration registers and all state-machines are reset in all clock domains (see [Table 20-7](#)).

Table 20-7. McSPI Hardware Reset

Peripherals	Name	Comments
McSPI module	CORE_RST	Same as global reset

20.4.2.4 Software Reset

The SPI_m.[MCSPI_SYSCONFIG](#)[1] SOFTRESET bit controls the software reset of the SPI interface. Writing 1 to this bit enables active software reset functionality, which is equivalent to a hardware reset. The bit is automatically reset by hardware.

NOTE: The SPI_m.[MCSPI_SYSCONFIG](#) register is not sensitive to software reset.

20.4.3 Hardware Requests

20.4.3.1 DMA Requests

Each channel includes two DMA requests, one for reception and one for transmission (see [Table 20-8](#)).

Table 20-8. DMA Requests

Attributes	DMA Request	Name	Mapping	Comments
SPI1				
	8	SPI1_DMA_TX0	S_DMA_34	Destination is system DMA (sDMA).
		SPI1_DMA_RX0	S_DMA_35	
		SPI1_DMA_TX1	S_DMA_36	
		SPI1_DMA_RX1	S_DMA_37	
		SPI1_DMA_TX2	S_DMA_38

SPI4				
	2	SPI4_DMA_TX0	S_DMA_69	Destination is sDMA.
		SPI4_DMA_RX0	S_DMA_70	

20.4.3.2 Interrupt Requests

Each McSPI module handles one interrupt line (see [Table 20-9](#)).

Table 20-9. Interrupt Requests

Attributes	Interrupt Request	Name	Mapping	Comments
SPI1				
	1	SPI1_IRQ	M_IRQ_65	Destination is the microprocessor unit (MPU) interrupt controller.
SPI2				
	1	SPI2_IRQ	M_IRQ_66	Destination is the MPU interrupt controller.
SPI3				
	1	SPI3_IRQ	M_IRQ_91	Destination the MPU interrupt controller.
SPI4				
	1	SPI4_IRQ	M_IRQ_48	Destination is the MPU interrupt controller.

20.4.3.3 Wake-Up Requests

[Table 20-10](#) lists the wake-up requests.

Table 20-10. Wake-Up Requests

Attributes	Wake Request	Name	Mapping	Comments
SPI1				
	1	spi1_cs0	SPI1_SWAKEUP	Destination is the PRCM module.
SPI2				
	1	spi2_cs0	SPI2_SWAKEUP	Destination is the PRCM module.
SPI3				
	1	spi3_cs0	SPI3_SWAKEUP	Destination is the PRCM module.
SPI4				
	1	spi4_cs0	SPI4_SWAKEUP	Destination is the PRCM module.

20.5 McSPI Functional Description

20.5.1 McSPI Block Diagram

Figure 20-13 shows the McSPI module.

Figure 20-13. McSPI Block Diagram

20.5.2 Master Mode

20.5.2.1 Master Mode Features

The McSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The McSPI initiates a data transfer on the data lines (spim_simo and spim_somi) and generates clock (spim_clk) and control signals (spim_cx).

Connected to multiple external devices, the McSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of McSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information on interrupts, see [Section 20.5.5.1, Interrupt Events in Master Mode](#)).

20.5.2.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on spim_simo) and received (shifted in serially on spim_somi) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the SPIIm.[MCSPI_CHxCONF\[13:12\]](#) TRM field).

Channel access to the shift registers for transmission/reception is based on the [MCSPI_TXx](#) transmitter register state, the [MCSPI_RXx](#) receiver register state, and round robin arbitration.

Channels that meet the following rules are included in the round robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

- Rule 1: Only enabled channels (the SPIIm.[MCSPI_CHxCTRL\[0\]](#) EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its [MCSPI_TXx](#) transmitter register is not empty (the SPIIm.[MCSPI_CHxSTAT\[1\]](#) TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the [MCSPI_TXx](#) register is empty when the shift register is assigned, the TXx_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also the transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the SPIIm.[MCSPI_CHxSTAT\[0\]](#) RXS bit) when the shift register is assigned (see also the receive-only mode). Therefore, the [MCSPI_RXx](#) register cannot be overwritten. Note that the SPI1.[MCSPI_IRQSTATUS\[3\]](#) RX0_OVERFLOW bit is never set to this mode.

When SPI word transfer completes (the SPIIm.[MCSPI_CHxSTAT\[2\]](#) EOT bit is set), the updated [MCSPI_TXx](#) register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (spim_clk) synchronizes shifting and sampling of the information on the two serial data lines (spim_simo and spim_somi). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

[Figure 20-14](#) shows an example of a full-duplex system with a master device (McSPI module m) on the left and a slave device on the right. After eight cycles of the serial clock spim_clk, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

Figure 20-14. SPI Full-Duplex Transmission (Example)

20.5.2.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents the MPU from reading the [MCSPI_RXx](#) register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the SPIIm.[MCSPI_CHxCONF\[13:12\]](#) TRM field). Transmission starts only after data is loaded into the [MCSPI_TXx](#) register.

Rule 1 and Rule 2, defined in [Section 20.5.2.2](#), are applicable in this mode.

Rule 3, defined in [Section 20.5.2.2](#), is not applicable.

In master transmit-only mode, the [MCSPI_RXx](#) register state FULL does not prevent transmission and the [MCSPI_RXx](#) register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the RX0_OVERFLOW bit in the SPIIm.[MCSPI_IHQSTATUS](#) register is never set in this mode.

The hardware automatically disables the RX_FULL interrupt and the DMA read requests.

The transfer status is given by the SPIIm.[MCSPI_CHxSTAT\[2\]](#) EOT bit.

20.5.2.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents the MPU from refilling the [MCSPI_TXx](#) register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the SPIIm.[MCSPI_CHxCONF\[13:12\]](#) TRM field).

The master receive-only mode enables channel scheduling only on the empty state of the [MCSPI_RXx](#) register.

Rule 1 and Rule 3, defined in [Section 20.5.2.2](#), are applicable in this mode.

Rule 2, defined in [Section 20.5.2.2](#), is not applicable.

In the master receive-only mode, software must write dummy data to the [MCSPI_TXx](#) register, and only after the TX buffer is empty (check the [MCSPI_CH0STAT\[2\]](#) bit in the software).. Only one dummy write is enough to receive any number of words from the slave. Software should ensure that the [MCSPI_TXx](#) register is always full (the [TXx_EMPTY](#) bits of SPIm.[MCSPI_IRQSTATUS](#)) when receiving. The content of the [MCSPI_TXx](#) register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the [MCSPI_TXx](#) register, the [TXx_EMPTY](#) and [TXx_UNDERFLOW](#) bits in the SPIm.[MCSPI_IRQSTATUS](#) register are never set in receive-only mode.

The SPIm.[MCSPI_CHxSTAT\[2\]](#) EOT bit gives the status of serialization. The [RXx_FULL](#) bits of the SPIm.[MCSPI_IRQSTATUS](#) register are set when received data is loaded from the shift register to the corresponding [MCSPI_RXx](#) register. The SPIm.[MCSPI_IRQSTATUS\[3\]](#) RX0_OVERFLOW bit is never set in this mode.

20.5.2.5 Single-Channel Master Mode

When the McSPI is configured as a master device with a single enabled channel, the assertion of the spim_csx signal can be controlled in two different ways:

- If the [MCSPI_MODULCTRL\[0\]](#) SINGLE bit is set to 0, spim_csx assertion/deassertion after each SPI word is automatically controlled by the McSPI module (see subsections of [Section 20.5.2.1, Master Mode Features](#)).
- If the [MCSPI_MODULCTRL\[0\]](#) SINGLE bit and the [MCSPI_CHxCONF\[20\]](#) FORCE bit are set to 1: spim_csx assertion/deassertion is controlled by software (see [Section 20.5.2.5.1, Programming Tips When Switching to Another Channel](#)).

20.5.2.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for completion of the SPI word transfer (wait until the SPIm.[MCSPI_CHxSTAT\[2\]](#) EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel first, and then enable the other channel.

20.5.2.5.2 Force spim_csx Mode

Continuous transfers are manually allowed by keeping the spim_csx signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the spim_csx line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the spim_csx active mode is supported when:

- A single channel is used (with the SPIm.[MCSPI_MODULCTRL\[0\]](#) SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (SPIm.[MCSPI_CHxCONF](#)).

The state of the spim_csx signal is programmable.

- Writing 1 to the SPIm.[MCSPI_CHxCONF\[20\]](#) FORCE bit drives the spim_csx line high when the SPIm.[MCSPI_CHxCONF\[6\]](#) EPOL bit is set to 0. spim_csx is driven low when the SPIm.[MCSPI_CHxCONF\[6\]](#) EPOL bit is set to 1.
- Writing 0 to the SPIm.[MCSPI_CHxCONF\[20\]](#) FORCE bit drives the spim_csx line low when the SPIm.[MCSPI_CHxCONF\[6\]](#) EPOL bit is set to 0. spim_csx is driven high when the SPIm.[MCSPI_CHxCONF\[6\]](#) EPOL bit is set to 1.
- A single channel is enabled (the SPIm.[MCSPI_CHxCTRL\[0\]](#) EN bit is set to 1). The first enabled channel activates the spim_csx line.

When the channel is enabled, the spim_csx signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the [MCSPI_TXx](#) register (the SPIm.[MCSPI_CHxSTAT\[1\]](#) TXS bit), the status of the [MCSPI_RXx](#) register (the SPIm.[MCSPI_CHxSTAT\[1\]](#) RXS bit), and the defined mode (the SPIm.[MCSPI_CHxCONF\[13:12\]](#) TRM field) of the channel enabled.

The SPIIm.[MCSPI_CHxSTAT\[2\]](#) EOT bit gives the transfer status of each SPI word. The RXx_FULL bit in the SPIIm.[MCSPI_IRQSTATUS](#) register is set when received data is loaded from the shift register to the [MCSPI_RXx](#) register.

A change in the configuration parameters is propagated directly on the SPI interface. If the spim_csx signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

NOTE: To avoid data corruption, spim_csx polarity and spim_clk phase and spim_clk polarity must not be modified when the spim_csx signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration (transmit-only for instance) to another (receive-only for instance) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the SPIIm.[MCSPI_CHxCTRL\[0\]](#) EN bit set to 0) and spim_csx can be forced to its inactive state using the SPIIm.[MCSPI_CHxCONF\[20\]](#) FORCE bit.

[Figure 20-15](#) and [Figure 20-16](#) show successive transfers with spim_csx maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

Figure 20-15. Continuous Transfers With spim_csx Maintained Active (Single-Data-Pin Interface Mode)

Figure 20-16. Continuous Transfers With spim_csx Maintained Active (Dual-Data-Pin Interface Mode)

NOTE: The turbo mode described in [Section 20.5.2.5.3, Turbo Mode](#), maintains spim_csx in active mode when the following conditions are met:

- A single channel is explicitly used (the SPIIm.[MCSPI_MODULCTRL\[0\]](#) SINGLE bit is set to 1).
- Turbo mode is enabled in the configuration of the channel. (The SPIIm.[MCSPI_CHxCONF\[19\]](#) TURBO bit is set to 1.)

20.5.2.5.3 Turbo Mode

The turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the **MCSPI_RXx** register are full. The turbo mode is useful (time savings) when a transfer exceeds two words. This mode is programmable per channel (via the SPI1.**MCSPI_CHxCONF[9]** TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 applies, but Rule 3 does not (see [Section 20.5.2.2](#)). An enabled channel can be scheduled if its receive register is full (the SPI1m.**MCSPI_CHxSTAT[0]** RXS bit) at the time of the shift-register assignment until the shift register is full.

The **MCSPI_RXx** register cannot be overwritten in turbo mode. Consequently, the SPI1m.**MCSPI_IRQSTATUS[3]** RX0_OVERFLOW bit is never set in this mode.

20.5.2.6 Start Bit Mode

In start bit mode, an extended bit is added before the SPI word in order to indicate whether the next SPI word must be handled as a command or as data. This feature is only available in master mode. The start bit mode cannot be used at the same time as turbo mode and/or force spim_csx mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the SPI1m.**MCSPI_CHxCONF[23]** SBE bit to 1. The polarity of the extended bit is programmable per channel. When the SPI1m.**MCSPI_CHxCONF[24]** SBPOL bit is set to 0, the SPI word must be handled as a command. When the SPI1m.**MCSPI_CHxCONF[24]** SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start bit transfer without disabling the channel for reconfiguration; in this case, users must configure the SPI1m.**MCSPI_CHxCONF[24]** SBPOL bit before writing the SPI word to be transmitted to the TX register.

20.5.2.7 Chip-Select Timing Control

The chip select timing control is only available in master mode with automatic chip select generation (**MCSPI_MODULCTRL[0]** SINGLE bit field set to 0), to add a programmable delay between chip select assertion and first clock edge, or chip select removal and last clock edge.

This mode is programmable per channel (the TCS bit of the SPI1m.**MCSPI_CHxCONF** register).

[Figure 20-17](#) shows the chip-select SPIEN timing control.

Figure 20-17. Chip-Select SPIEN Timing Controls

NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between chip-select assertion and the first clock edge with PHA = 1 or between chip-select removal and the last clock edge with PHA = 0.

20.5.2.8 Programmable SPI Clock (spim_clk)

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPIm_FCLK, is used as input of a programmable divider (the SPIm.[MCSPI_CHxCONF\[5:2\]](#) CLKD field) to generate the bit rate of the serial output clock spim_clk. Table 20-11 summarizes the supported divisor values.

Table 20-11. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz
2	24 MHz
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192	~5.8 kHz
16384	~2.9 kHz
32768	~1.5 kHz

20.5.2.8.1 Clock Ratio Granularity

By default the clock division ratio is defined by the SPIm.[MCSPI_CHxCONF\[5:2\]](#) CLKD bit field with power of two granularity leading to a clock division in range 1 to 4096, in this case the duty cycle is always 50%. With the SPIm.[MCSPI_CHxCONF\[29\]](#) CLKG bit, clock division granularity can be changed to one clock cycle, in that case the SPIm.[MCSPI_CHxCTRL\[15:8\]](#) EXTCLK bit field is concatenated with SPIm.[MCSPI_CHxCONF\[5:2\]](#) CLKD bit field to give a 12-bit width division ratio in range 1 to 4096.

When granularity is one clock cycle (CLKG set to 1), for odd value of clock ratio the clock high level lasts one clock cycle more than low level depending on SPIm.[MCSPI_CHxCONF\[1\]](#) POL bit and SPIm.[MCSPI_CHxCONF\[0\]](#) PHA bit refer to [Table 20-12](#).

Table 20-12. CLKSPIO High/Low Time Computation

Clock ratio Fratio	CLKSPIO High Time	CLKSPIO Low Time
1	T _{high_ref}	T _{low_ref}
Even \geq 2	T _{ref} * (Fratio/2)	T _{ref} * (Fratio/2)
Odd \geq 3 (POL=PHA)	T _{ref} * (Fratio-1) /2	T _{ref} * (Fratio+1) /2
Odd \geq 3 (POL \neq PHA)	T _{ref} * (Fratio+1) /2	T _{ref} * (Fratio-1) /2

NOTE: Fratio = spi1_clk frequency (Fout) division ratio.
 Thigh = spi1_clk High Time period.
 Tlow = spi1_clk Low Time period.
 T_{ref} = SPI1_FCLK period.
 Thigh_ref = SPI1_FCLK high Time period.
 Tlow_ref = SPI1_FCLK low Time period.

If CLKG = 1: Fratio = EXTCLK concatenated with CLKD + 1 as shown below:

Fratio - 1											
11	10	9	8	7	6	5	4	3	2	1	0
SPI1.MCSPI_CHxCTRL[15:8] EXTCLK bit field								SPI1.MCSPI_CHxCONF[5:2] CLKD bit field			
15	14	13	12	11	10	9	8	5	4	3	2

For odd ratio values, the duty cycle is calculated as below:

$$\text{Duty_cycle} = (1-1/\text{Fratio})/2$$

Table 20-13 shows clock granularity examples with a clock source frequency of 48 MHz.

Table 20-13. Clock Granularity Examples

EXTCLK	CLKD	CLKG	Fratio	PHA	POL	Thigh (ns)	Tlow (ns)	Tperiod (ns)	Duty Cycle	Fout (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50-50	48
X	1	0	2	X	X	20.8	20.8	41.6	50-50	24
X	2	0	4	X	X	41.6	41.6	83.2	50-50	12
X	3	0	8	X	X	83.2	83.2	166.4	50-50	6
0	0	1	1	X	X	10.4	10.4	20.8	50-50	48
0	1	1	2	X	X	20.8	20.8	41.6	50-50	24
0	2	1	3	1	0	41.6	20.8	62.4	66-33	16
0	2	1	3	1	1	20.8	41.6	62.4	33-66	16
0	3	1	4	X	X	41.6	41.6	83.2	50-50	12
5	0	1	81	1	0	852.8	832	1684.8	50.6-49.4	0.592
5	7	1	88	X	X	915.2	915.2	1830.4	50-50	0.545

20.5.3 Slave Mode

To select the McSPI slave mode, set the SPI1.MCSPI_MODULCTRL[2] MS bit.

A McSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the McSPI initiates data transfer on the data lines (spim_simo and spim_somi) when it is selected by an active control signal (spim_csx) and receives an SPI clock (spim_clk) from the external SPI master device. Only channel 0 can be configured as a slave. In slave mode, the McSPI uses the edge of spim_csx to detect word length. For this reason, spim_csx must become inactive between each word.

The McSPI does not support spim_csx active between SPI words. It uses the edge to detect word length.

20.5.3.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section registers name such as SPI1.MCSPI_CHxCTRL stand for SPI1.MCSPI_CH0CTRL where x=0 (channel 0 control register).

Figure 20-18 shows an example of four slaves wired on a single master device.

Figure 20-18. Example of McSPI Slave With One Master and Multiple Slave Devices on Channel 0

mcsipi-017

The channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the SPIm.[MCSPI_CHxCTRL\[0\]](#) EN bit (with x=0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected only on spim_cs0.
- Its own transmitter register, SPIm.[MCSPI_TXx](#) (with x=0), on top of the common transmit shift register. If the [MCSPI_TXx](#) register is empty, the SPIm.[MCSPI_CHxSTAT\[1\]](#) TXS bit (with x=0) is set. If McSPI is selected by an external master (the active signal on the spim_csx port assigned to channel 0), the [MCSPI_TXx](#) register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The [MCSPI_TXx](#) register must be loaded before McSPI is selected by a master.
- Its own receiver register, SPIm.[MCSPI_RXx](#) (with x=0), on top of the common receive shift register. If the [MCSPI_RXx](#) register is full, the SPIm.[MCSPI_CHxSTAT\[0\]](#) RXS bit (with x=0) is set.

NOTE: The [MCSPI_TXx](#) register and [MCSPI_RXx](#) registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the SPIm. [MCSPI_CHxCONF](#) register (with x=0):
 - Transmit and receive modes, programmable with the TRM field
 - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPIm modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)
 - SPI word length, programmable with the WL bit
 - spim_csx polarity, programmable with the EPOL bit

- spim_clk polarity, programmable with the POL bit
- spim_clk phase, programmable with the PHA bit

The spim_clk frequency of a transfer is controlled by the external SPI master connected to the McSPI slave device. The SPIIm.[MCSPI_CHxCONF\[5:2\]](#) CLKD field (with x=0) is not used in slave mode.

NOTE: The configuration of the channel can be loaded in the SPIIm.[MCSPI_CHxCONF](#) register (with x=0) only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of McSPI. DMA requests are asserted using the SPIIm.[MCSPI_CHxCONF\[15\]](#) DMAR bit (with x=0) for reading and the SPIIm.[MCSPI_CHxCONF\[14\]](#) DMAW bit (with x=0) for writing.
- Four interrupt events (see [Section 20.5.5.2, Interrupt Events in Slave Mode](#))

20.5.3.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the SPIIm.[MCSPI_CHxCONF\[13:12\]](#) TRM field (with x=0) to 0x0).

In slave transmit-and-receive mode, the [MCSPI_TXx](#) register must be loaded before McSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The [MCSPI_TXx](#) register content is always loaded in the shift register whether it is updated or not. The event TXx_UNDERFLOW is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the SPIIm.[MCSPI_CHxSTAT0\[2\]](#) EOT bit (with x=0) set to 1), the received data is transferred to the channel receive register.

To use McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the [MCSPI_RXx](#) register state (see [Section 20.5.5.2, Interrupt Events in Slave Mode](#)).

20.5.3.3 Slave Transmit-Only Mode

The slave transmit-only mode is programmable (set the SPIIm.[MCSPI_CHxCONF\[13:12\]](#) TRM field (with x=0) to 0x2) and avoids the requirement for the MPU to read the [MCSPI_RXx](#) register (minimizing data movement) only when transmission is meaningful.

To use the McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled because of the [MCSPI_RXx](#) register state.

When the SPI word transfer completes, the SPIIm.[MCSPI_CHxSTAT\[2\]](#) EOT bit is set (with x=0).

[Figure 20-19](#) shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave device, 1 bit transfers in the master. After eight cycles of the serial clock spim_clk, WordB transfers from the slave to the master.

Figure 20-19. SPI Half-Duplex Transmission (Transmit-Only Slave)

20.5.3.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the SPIIm.[MCSPI_CHxCONF\[13:12\]](#) TRM field (with x=0) to 0x1).

In receive-only mode, the [MCSPI_TXx](#) register must be loaded before the McSPI is selected by an external SPI master device. The [MCSPI_TXx](#) register content is always loaded into the shift register whether it is updated or not. The TXx_UNDERFLOW event is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the SPIIm.[MCSPI_CHxSTAT0\[2\]](#) EOT bit (with x=0) is set to 1), the received data is transferred to the channel receive register.

To use the McSPI as a slave receive-only device, the TXx_EMPTY and TXx_UNDERFLOW interrupts and the DMA write requests must be disabled due to the [MCSPI_TXx](#) register state.

For a full-duplex transmission, the serial clock (spim_clk) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If spim_clk synchronizes on a single serial data line, the data line should be half-duplex.

[Figure 20-20](#) shows an example of a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock spim_clk, Word A transfers from the master to the slave.

Figure 20-20. SPI Half-Duplex Transmission (Receive-Only Slave)

20.5.4 FIFO Buffer Management

The McSPI controller has a built-in 64 bytes buffer to unload DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at once and is selected by setting SPIIm.**MCSPI_CHxCONF[28]** FFER bit or SPIIm.**MCSPI_CHxCONF[27]** FFEW bit to 1. If several channel are selected and several FIFO enable bit fields set to 1, the controller forces buffer not to be used, it is the responsibility of the driver to set only one FIFO enable bit field.

The buffer can be used in the modes defined below:

- Master or Slave mode.
- Transmit only, Receive only or Transmit/Receive mode.
- Single channel or turbo mode, or in normal round robin mode. In round robin mode the buffer is used by only one channel.
- Every word length SPIIm.**MCSPI_CHxCONF[11:7]** WL are supported.

In transmit/receive mode, the buffer can be used in transmit (see [Figure 20-21](#)) or receive (see [Figure 20-22](#)) directions, or in both directions. If only one direction is chosen in transmit/receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two 32-byte buffers, one for each direction. See [Figure 20-23](#).

Figure 20-21. Buffer Use in Transmit Direction Only

mcspi-102

Figure 20-22. Buffer Use in Receive Direction Only

mcspi-103

Figure 20-23. Buffer Used For Both Transmit/Receive Directions

mcspi-101

Two levels SPIm.MCSPI_XFERLEVEL[5:0] AEL and SPIm.MCSPI_XFERLEVEL[13:8] AFL rule the buffer management. The granularity of these levels is one byte, then it is not aligned with SPI word length. It is the responsibility of the driver to set these values as a multiple of SPI word length defined in WL. Table 20-14 shows the number of byte written in the FIFO depending on the word length.

Table 20-14. FIFO Writes, Word Length Relationship

SPI Word Length WL	$3 \leq WL \leq 7$	$8 \leq WL \leq 15$	$16 \leq WL \leq 31$
Number of byte written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or FIFO configuration changes.

20.5.4.1 Buffer Almost Full

The MCSPI_XFERLEVEL[13:8] AFL bit field is needed when the buffer is used to receive SPI word from a slave ([MCSPI_CHxCONF\[28\]](#) FFER bit must be set to 1). It defines the Almost Full buffer status. See [Figure 20-24](#).

When FIFO pointer reaches this level an interrupt or a DMA request is sent to the MPU to enable system to read AFL+1 bytes from Receive register. Be careful AFL+1 must correspond to a multiple value of [MCSPI_CHxCONF\[11:7\]](#) WL bit field.

When DMA is used, the request is de-asserted after the first Receive register read.

No new request will be asserted again as long as system has not performed the right number of read accesses.

Figure 20-24. Buffer Almost Full Level (AFL)

mcspi-043

NOTE: [MCSPI_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_RXx request is asserted on the same conditions than the [MCSPI_IRQSTATUS RXx_FULL](#) flag.

20.5.4.2 Buffer Almost Empty

The MCSPI_XFERLEVEL[5:0] AEL bit field is needed when the buffer is used to transmit SPI word to a slave ([MCSPI_CHxCONF\[27\]](#) FFEW bit must be set to 1). It defines the Almost Empty buffer status. See [Figure 20-25](#).

When FIFO pointer has not reached this level an interrupt or a DMA request is sent to the MPU to enable system to write AEL+1 bytes to Transmit register. Be careful AEL+1 must correspond to a multiple value of [MCSPI_CHxCONF\[11:7\]](#) WL bit field.

When DMA is used, the request is de-asserted after the first Transmit register write.

No new request will be asserted again as long as system has not performed the right number of write accesses.

Figure 20-25. Buffer Almost Empty Level (AEL)

NOTE: [MCSPI_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the SPI_m_DMA_TX_x request is asserted on the same conditions than the [MCSPI_IRQSTATUS](#) TX_x_EMPTY flag.

20.5.4.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user shall previously configure in the MCSPI_XFERLEVEL register the AEL and AFL levels and especially the MCSPI_XFERLEVEL[31:16] WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter allows the controller to stop the transfer correctly after a defined number of SPI word transfers. If WNCT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel, in this case the user does not know how many SPI transfers have been done. For received words, software shall poll the CHxSTAT[5] RXFFE bit and read the [MCSPI_RX_x](#) Receive register to empty the FIFO buffer.

When the End Of Word count interrupt is generated ([MCSPI_IRQSTATUS](#)[17] EOW bit set), the user can disable the channel and poll the [MCSPI_CHxSTAT](#)[5] RXFFE bit to know it lasts SPI words in the FIFO buffer and read them.

No new request will be asserted again as long as system has not performed the right number of write accesses.

NOTE: The status bit RXFFE shows only the FIFO status. The data received are stored not only in the FIFO, but also in the shift register and MCSPI_RX register. Therefore, the FIFO can be empty even after receiving two words.

20.5.5 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the SPI_m.[MCSPI_IRQSTATUS](#) register (RX_x_FULL, TX_x_UNDERFLOW, TX_x_EMPTY, ...) with x = [0,3] that indicate if service is required. Each status bit has an interrupt enable bit (a mask) in the SPI_m.[MCSPI_IRQENABLE](#) register (RX_x_FULL_ENABLE, TX_x_UNDERFLOW_ENABLE, TX_x_EMPTY_ENABLE, ...).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The McSPI supports interrupt-driven and polling operations.

20.5.5.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the [MCSPI_TXx](#) register state are TXx_EMPTY and TXx_UNDERFLOW. The interrupt event related to the [MCSPI_RXx](#) register state is RXx_FULL.

20.5.5.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its [MCSPI_TXx](#) register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see [Section 20.5.2.4, Master Receive-Only Mode](#)). When the FIFO buffer is enabled ([MCSPI_CHxCONF\[27\]](#) FF EW bit set to 1), the [MCSPI_IRQSTATUS](#) TXx_EMPTY bit is set as soon as there is enough space in buffer to write a number of bytes defined by the [MCSPI_XFERLEVEL\[5:0\]](#) AFL bit field.

The [MCSPI_TXx](#) register must be loaded with data to remove the source of the interrupt; the SPIm.[MCSPI_IRQSTATUS](#) TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the [MCSPI_TXx](#) register defined by [MCSPI_XFERLEVEL\[5:0\]](#) AFL bit field. It is the responsibility of the MPU to perform the right number of writes.

20.5.5.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the [MCSPI_TXx](#) register or if the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in master mode.

To avoid having TXx_UNDERFLOW event at the beginning of a transmission, the event TXx_UNDERFLOW is not activated when no data has been loaded into the [MCSPI_TXx](#) register since channel has been enabled. To avoid having TXx_UNDERFLOW event, the [MCSPI_TXx](#) register must be loaded seldom.

The SPIm.[MCSPI_IRQSTATUS](#) TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

20.5.5.1.3 RXx_FULL

The RXx_FULL event is activated when channel is enabled and [MCSPI_RXx](#) register becomes filled (transient event). When FIFO buffer is enabled ([MCSPI_CHxCONF\[28\]](#) FF ER bit set to 1), the RXx_FULL is asserted as soon as the number of bytes holds in the FIFO to be read reaches the [MCSPI_XFERLEVEL\[13:8\]](#) AFL threshold.

The [MCSPI_RXx](#) register must be read to remove the source of the interrupt; the [MCSPI_IRQSTATUS](#) RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event will be asserted as soon as the MPU has not performed AFL+1 reads into [MCSPI_RXx](#). It is the responsibility of MPU to perform the right number of reads.

20.5.5.1.4 End Of Word Count

The [MCSPI_IRQSTATUS\[17\]](#) EOW event (End Of Word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in the [MCSPI_XFERLEVEL\[31:16\]](#) WCNT bit field. If WCNT is set to 0x0000, the counter is not enable and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as [MCSPI_XFERLEVEL\[31:16\]](#) WCNT is not reloaded and the channel is not re-enabled.

The [MCSPI_IRQSTATUS\[17\]](#) EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

20.5.5.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the [MCSPI_TXx](#) register state are TXx_EMPTY and TXx_UNDERFLOW. The interrupt events related to the [MCSPI_RXx](#) register state are RXx_FULL and RX0_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the [MCSPI_IRQSTATUS](#) register.

20.5.5.2.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its [MCSPI_TXx](#) register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled ([MCSPI_CHxCONF\[27\]](#) FFEW bit set to 1), the TXx_EMPTY event is asserted as soon as there is enough space in buffer to write a number of byte defined by the [MCSPI_XFERLEVEL\[5:0\]](#) AFL bit field.

The [MCSPI_TXx](#) register must be loaded with data to remove the source of the interrupt; the SPIm.[MCSPI_IRQSTATUS](#) TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the [MCSPI_TXx](#) register defined by [MCSPI_XFERLEVEL\[5:0\]](#) AFL bit field. It is the responsibility of the MPU to perform the right number of writes.

20.5.5.2.2 TXx_UNDERFLOW

The TXx_UNDERFLOW event is activated when a channel is enabled and if the [MCSPI_TXx](#) register is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

When FIFO is enabled, the data emitted while underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data is the FIFO has been reset).

TXx_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when data is not loaded into the [MCSPI_TXx](#) register because the channel is enabled.

The SPIm.[MCSPI_IRQSTATUS](#) TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

20.5.5.2.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the [MCSPI_RXx](#) register is being filled (transient event). When FIFO buffer is enabled ([MCSPI_CHxCONF\[28\]](#) FFER bit set to 1), RXx_FULL is asserted as soon as there is a number of bytes holds in buffer to read defined by the [MCSPI_XFERLEVEL\[13:8\]](#) AFL bit field.

The [MCSPI_RXx](#) register must be read to remove the source of the interrupt; the SPIm.[MCSPI_IRQSTATUS](#) RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event will be asserted as soon as the MPU has not performed AFL+1 reads into [MCSPI_RXx](#). It is the responsibility of MPU to perform the right number of reads.

20.5.5.2.4 RX0_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in either transmit-and-receive or receive-only mode, when a channel is enabled and the [MCSPI_RXx](#) register or FIFO is full when a new SPI word is received. The [MCSPI_RXx](#) register is always overwritten with the new SPI word. If the FIFO is enabled data within the FIFO are overwritten, it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW indicates an error (data loss) in slave mode.

The [MCSPI IRQSTATUS\[3\]](#) RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

20.5.5.2.5 End Of Word Count

The [MCSPI IRQSTATUS\[17\]](#) EOW event (End Of Word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in the [MCSPI_XFERLEVEL\[31:16\]](#) WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as WCNT is not reloaded and channel re-enabled.

The [MCSPI IRQSTATUS\[17\]](#) EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

20.5.5.3 Interrupt-Driven Operation

An interrupt enable bit, in SPIm.[MCSPI IRQENABLE](#) register, can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the MPU must:

- Read the SPIm.[MCSPI IRQSTATUS](#) register to identify which event occurred.
- Read the [MCSPI_RXx](#) register that corresponds to the event to remove the source of an RXx_FULL event or write into the [MCSPI_TXx](#) register that corresponds to the event to remove the source of a TXx_EMPTY event. No action is required to remove the source of the WKS (wake-up), TXx_UNDERFLOW, and RX0_OVERFLOW events.
- Write 1 into the corresponding bit of the SPIm.[MCSPI IRQSTATUS](#) register to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

20.5.5.4 Polling

When the interrupt capability of an event is disabled in the SPIm.[MCSPI IRQENABLE](#) register, the interrupt line is not asserted, but the status bits in the SPIm.[MCSPI IRQSTATUS](#) register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx_FULL: To remove the source of the event, the MPU must read the corresponding [MCSPI_RXx](#) register.
- TXx_EMPTY: To remove the source of the event, the MPU must write into the corresponding [MCSPI_TXx](#) register.
- WKS (wake-up), TXx_UNDERFLOW, and RX0_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the SPIm.[MCSPI IRQSTATUS](#) register to 1. This does not affect the interrupt line state.

20.5.6 DMA Requests

The sDMA controller module manages DMA accesses. The sDMA controller advantage is to lower the MPU charge for data transfers.

Each McSPI channel can issue DMA requests if they are enabled. There are two DMA request lines per McSPI channel (one for read and one for write).

The DMA read request line is asserted when the McSPI channel is enabled and new data is available in the receive register of the McSPI channel. A DMA read request can be individually masked with the SPI1.[MCSPI_CHxCONF\[15\]](#) DMAR bit. The DMA read request line is deasserted on read completion of the [MCSPI_RXx](#) register of the McSPI channel.

The DMA write request line is asserted when the McSPI channel is enabled and the [MCSPI_TXx](#) register of the McSPI channel is empty. A DMA write request can be individually masked with the SPI1.[MCSPI_CHxCONF\[14\]](#) DMAW bit. The DMA write request line is deasserted on load completion of the [MCSPI_TXx](#) register of the channel.

20.5.7 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The McSPI is compliant with the idle and wake-up system handshake protocol.

20.5.7.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogating) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The SPI1.[MCSPI_SYSCONFIG\[0\]](#) AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the McSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the McSPI is selected by the external master.

20.5.7.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the CORE_48M_FCLK or CORE_L4_ICLK output clocks (see [Chapter 3, Power, Reset, and Clock Management](#), for details), the PRCM module automatically launches a hardware handshake protocol to ensure that the McSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an idle request to the McSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the McSPI module acknowledges the PRCM idle request is configurable through the McSPI.SYSCONFIG[4:3] SIDLEMODE bit.

The following list details the settings of the SIDLEMODE bit and the related acknowledgment modes:

- Force-idle mode (the SPI1.[MCSPI_SYSCONFIG\[4:3\]](#) SIDLEMODE bit set to 0x0): the McSPI module acknowledges unconditionally the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit set to 0x1): The McSPI module never acknowledges an idle request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit set to 0x2): The McSPI module acknowledges the idle request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the McSPI module also offers an additional granularity on the CORE_48M_FCLK and CORE_L4_ICLK gating. The SPI1.[SYSCONFIG\[9:8\]](#) CLOCKACTIVITY bit field determines which clock shuts down (the CORE_48M_FCLK, the CORE_L4_ICLK, neither clock, or both clocks).

The CLOCKACTIVITY setting is used internally to McSPI to determine on which part of the module the conditions to acknowledge the PRCM idle request are tested. For example, if CORE_48M_FCLK is not shut down on a PRCM idle request, McSPI considers only CORE_L4_ICLK and the associated pending activities before acknowledging the request.

Some McSPI features are associated with CORE_L4_ICLK and others with CORE_48M_FCLK. Using the CLOCKACTIVITY bit field along with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if McSPI acknowledges an idle request.

The following list details CLOCKACTIVITY settings and the associated features:

- CLOCKACTIVITY set to 00: ICLK OFF and FCLK OFF, both ICLK and FCLK are taken into account for generating the acknowledge. This setting also means that both FCLK and ICLK are likely to be shut down on a PRCM idle request.
- CLOCKACTIVITY set to 01: ICLK ON and FCLK OFF, ICLK is not shut down on a PRCM idle request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK OFF and FCLK ON, FCLK is not shut down on a PRCM idle request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK ON and FCLK ON, none of the clocks are shut down. This means McSPI can potentially acknowledge the idle request without checking the internal functionalities linked to its clocks.

CAUTION

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, the software must ensure consistent programming between the CLOCKACTIVITY and the PRCM CORE_48M_FCLK and CORE_L4_ICLK control bits. If the McSPI is disabled in both the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its idle request, which is acknowledged regardless of the features associated with the McSPI clocks. This can lead to unpredictable behavior.

20.5.7.2.1 Wake-Up Event in Smart-Idle Mode

The module wake-up feature is enabled when both the SPIIm.[MCSPI_SYSCONFIG\[2\]](#) ENAWAKEUP and SPIIm.[MCSPI_WAKEUPENABLE\[0\]](#) WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wake-up request to the system power manager to switch the interface clock and the functional clock back. A wake-up is requested when channel 0 is enabled and an asynchronous selection occurs on the spim.csx port associated with channel 0 (see the definition for the SPIIm.[MCSPI_CHxCONF](#) SPIENSLV field (with x=0) in the register description table).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- *Before the beginning* of the second SPI word serialization when McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- *Before the end* of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the SPIIm.[MCSPI_RXx](#) register (with x=0) before the completion of the second SPI word serialization.

[Table 20-15](#) lists the supported cases in wake-up mode.

Table 20-15. Smart-Idle Mode and Wake-Up Capabilities

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Master	Must be maintained	Must be maintained	Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode.	No wake-up event

Table 20-15. Smart-Idle Mode and Wake-Up Capabilities (continued)

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Slave	Can be switched off	Can be switched off	An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode.	The module asynchronously sends a wake-up request if an event on the spim_csx port associated to channel 0 is detected.

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

20.5.7.2.2 Transitions From Smart-Idle Mode to Normal Mode

The McSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the SPIm.[MCSPI_IRQSTATUS](#)[16] WKS bit) is updated with the event causing the wake-up; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the SPIm.[MCSPI_IRQENABLE](#)[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable/disable controls, accessible through the SPIm.[MCSPI_IRQENABLE](#) and SPIm.[MCSPI_WAKEUPENABLE](#) registers. Software must ensure the overall consistency.

The interrupt status register SPIm.[MCSPI_IRQSTATUS](#) is updated with the event causing the wake-up; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

20.5.7.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the SPIm.[MCSPI_SYSCONFIG](#)[4:3] SIDLEMODE field is set to 0x0. In force-idle mode, McSPI responds unconditionally to the idle request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if both the SPIm.[MCSPI_SYSCONFIG](#)[2] ENAWAKEUP and SPIm.[MCSPI_WAKEUPENABLE](#)[0] WKEN bits are set.

The transition from normal mode to idle mode does not affect the interrupt event bits of the SPIm.[MCSPI_IRQSTATUS](#) register.

In force-idle mode, the module must be disabled so the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the McSPI can be switched off.

An idle request during an SPI data transfer can lead to an unexpected and unpredictable result. The software must avoid such a request.

- The module exits force-idle mode through the idle and wake-up hardware handshake protocol. The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

20.6 McSPI Basic Programming Model

20.6.1 Initialization of Modules

Figure 20-26 shows the overview of the module initialization flow process. Section 20.6.2 and Section 20.6.3 show the steps required to configure McSPI modes.

Figure 20-26. Module Initialization Flow

mcspi-018

NOTE: Before the SPIIm.MCSPI_SYSSTATUS[0] RESETDONE bit is set, the CLK and CLKSPIREF clocks must be provided to the module.

To avoid unpredictable behavior, reset the module before changing from master mode to slave mode, or vice versa.

20.6.2 Transfer Procedures without FIFO

In the subsections below, the transfer procedures are described without FIFO using (MCSPI_CHxCONF[27:28] FFER and FF EW = 0).

The McSPI allows the transfer of one or more words based on the different modes:

- Master normal, master turbo, slave
- Transmit-and-receive, transmit-only, receive-only

- Write and read requests: Interrupts, DMA
- spi1_csx line assertion/deassertion: Automatic, manual

For these flows, the host process contains the main process and the interrupt routines. The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

20.6.2.1 Common Transfer Procedure

Figure 20-27 shows the main sequence common to all transfers. In multichannel master mode, the flows of different channels can be run simultaneously.

Figure 20-27. Common Transfer Sequence: Main Process

mcspi-030

20.6.2.2 End-of-Transfer Procedure

For transfers carried out with DMA or interrupt mode, the end of transfer must be achieved by following the steps shown in the flowcharts corresponding to Table 20-16, which summarizes the end-of-transfer types per transfer mode and provides cross-references for further information.

Table 20-16. End-of-Transfer Sequences

		Transmit Receive		Transmit Only		Receive Only	
		Interrupt	DMA	Interrupt	DMA	Interrupt	DMA
Master normal	End of transfer sequence	See Section 20.6.2.3		See Section 20.6.2.4	See Section 20.6.2.4	See Section 20.6.2.5.1	See Section 20.6.2.5.1
	Minimum number of words	1	1	1	1	1	1
	DMA transfer size ⁽¹⁾		w		w		w - 1
Master turbo	End of transfer sequence	See Section 20.6.2.3		See Section 20.6.2.4	See Section 20.6.2.4	See Section 20.6.2.5.2	See Section 20.6.2.5.2
	Minimum number of words	1	1	1	1	2	3
	DMA transfer size ⁽¹⁾		w		w		w - 2
Slave	End of transfer sequence	See Section 20.6.2.3		See Section 20.6.2.4	See Section 20.6.2.4	See Section 20.6.2.5.3	
	Minimum number of words	1	1	1	1	1	1
	DMA transfer size ⁽¹⁾		w		w	w	w

⁽¹⁾ w = number of words to transfer

The different sequences can be merged in one process to manage transfers of several types. The end-of-transfer sequences are described from the start of the channel.

In these sequences and in later sections of this chapter, some software variables are used:

- WRITE_COUNT (= 0 at initialization): Contains the number of words to transfer
- READ_COUNT (= 0 at initialization): Contains the number of words to receive
- CHANNEL_ENABLE (= false at initialization)
- LAST_TRANSFER (= false at initialization): Indicates that the last word is in transmission
- LAST_REQUEST (= false at initialization): Indicates that the last request is in progress

All variables are initialized before starting the channel.

20.6.2.3 Transmit and Receive Procedure

[Figure 20-28](#) shows the handling procedure for words received and transmitted by interrupt in master and slave modes. The main process flow shows how the end of the transfer must be done after all words are received for this mode.

If the requests are configured in DMA, WRITE_COUNT and READ_COUNT are assigned with the value w when the DMA handler completes w interface accesses.

Figure 20-28. Transmit and Receive (Master and Slave)

mcspi-033

20.6.2.4 Transmit-Only Procedure

20.6.2.4.1 Based on Interrupt Requests

Figure 20-29 shows the handling procedure for words transmitted by interrupt in transmit-only mode. The main process flow shows how the end-of-transfer must be done after all words are received for this mode.

Figure 20-29. Transmit-Only With Interrupts (Master and Slave)

mcspi-023

20.6.2.4.2 Transmit-Only Based on DMA Write Requests

In Figure 20-30, the main process shows completion of the transfer of words in transmit-only mode with DMA write requests.

When the DMA handler completes w interface accesses, $WRITE_COUNT$ is assigned the value w .

Figure 20-30. Transmit-Only With DMA (Master and Slave)

mcspi-024

20.6.2.5 Receive-Only Procedure

20.6.2.5.1 Master Normal Receive-Only Procedure

20.6.2.5.1.1 Based on Interrupt Requests

Figure 20-31 shows the handling procedure for words received by interrupt in master normal receive-only mode. The main process flow shows how the end-of-transfer must be done after all words are received for this mode.

Figure 20-31. Receive Only With Interrupt (Master Normal)

20.6.2.5.1.2 Receive-Only Based on DMA Read Requests

In Figure 20-32, the main process shows the completion of a word transfer in receive-only mode with DMA read requests.

When the DMA handler completes $w - 1$ interface accesses, READ_COUNT is assigned the value $w - 1$.

Figure 20-32. Receive-Only With DMA (Master Normal)

mcspi-025

20.6.2.5.2 Master Turbo Receive-Only Procedure

20.6.2.5.2.1 Based on Interrupt Requests

Figure 20-33 shows the handling procedure for words received by interrupt in master turbo receive-only mode. The main process shows how the end-of-transfer must be done after all words are received for this mode.

Figure 20-33. Receive-Only With Interrupt (Master Turbo)

20.6.2.5.2.2 Based on DMA Read Requests

In Figure 20-34, the main process shows the completion of a word reception in master turbo receive-only mode with DMA write requests.

When the DMA handler completes $w - 2$ interface accesses, READ_COUNT is assigned the value $w - 2$.

Figure 20-34. Receive-Only With DMA (Master Turbo)

mcsipi-028

20.6.2.5.3 Slave Receive-Only Procedure

Figure 20-35 shows the handling procedure for words received by interrupt in slave receive-only mode. The main process shows how the end-of-transfer must be done after all words are received for this mode.

If the requests are configured in DMA, READ_COUNT is assigned the value w when the DMA handler completes w interface processes.

Figure 20-35. Receive Only (Slave)

mcspi-035

20.6.2.6 McSPI Configuration and Operations Example

This section details an example of a typical configuration.

[Figure 20-36](#) shows an implementation of successive transfers between two devices (slave) and the McSPI1 (master) in transmit-and-receive mode.

McSPI1 is the master, and spi1_simo shifts out the data to the external slaves. spi1_somi is connected to the data output port of two slave devices. The McSPI1 controls the first device with the spi1_cs0 signal (active low) for the exchange of 9-bit words synchronized with an active-high SPI clock.

The second device is controlled by the spi1_cs1 control signal (active high) for the exchange of 4-bit words synchronized with a SPI clock (active low) with a slower frequency than used with the first slave device.

Figure 20-36. Two SPI Transfers With PHA = 0 (Flexibility of McSPI)

mcspi-036

This section details the steps required for this type of transmission.

20.6.2.6.1 McSPI Initialization Sequence

As shown in [Figure 20-26](#), the McSPI module must first reset all registers and all state-machines.

For a software reset:

1. Set the SPI1.[MCSPI_SYSCONFIG\[1\]](#) SOFTRESET bit to 1.
2. Read the SPI1.[MCSPI_SYSSTATUS\[0\]](#) RESETDONE bit and check that it is set to 1.

20.6.2.6.2 Operations for the First Slave (On Channel 0)

20.6.2.6.2.1 Programming in Polling Mode

20.6.2.6.2.1.1 Mode Selection

The SPI1.[MCSPI_CHxCONF](#) register (with x = 0) allows configuration of the operating mode:

1. Set the SPI1.[MCSPI_CHxCONF\[18\]](#) IS bit to 0 for the spi1_somi pin in receive mode.
2. Set the SPI1.[MCSPI_CHxCONF\[17\]](#) DPE1 bit to 0 and the SPI1.[MCSPI_CHxCONF\[16\]](#) DPE0 bit to 1 for the spi1.simo pin in transmit mode.
3. Set the SPI1.[MCSPI_CHxCONF\[13:12\]](#) TRM field to 0x0 for transmit and receive mode.
4. Write 0x8 in the SPI1.[MCSPI_CHxCONF\[11:7\]](#) WL field for 9-bit word length.

5. Set the SPI1.[MCSPI_CHxCONF](#)[6] EPOL bit to 1 for spi1_cs0 activated low during active state.
6. Set the SPI1.[MCSPI_CHxCONF](#)[1] POL bit to 0 for spi1_clk held high during active state.
7. Set the SPI1.[MCSPI_CHxCONF](#)[0] PHA bit to 0 for data latched on odd-numbered edges of the SPI clock.

Clock Initialization and spi1_cs0 Enable

In master mode, the SPI must provide the clock and enable the channel:

8. Set the SPI1.[MCSPI_MODULCTRL](#)[2] MS bit to 0 to provide the clock.
9. Set the INPUTENABLE bit of the corresponding CONTROL_PADCONF_x register to achieve the synchronous clock by using loopback through the output and input buffers of the pad.
10. Set the SPI1.[MCSPI_CHxCTRL](#)[0] EN bit to 1 (where x = 0) to enable channel 0.

20.6.2.6.2.1.2 Write Operation

1. Write 1 to the SPI1.[MCSPI_IRQSTATUS](#)[0] TX0_EMPTY bit to reset the status.
2. Write the command/address or data value in the SPI1.[MCSPI_TX0](#) register to transmit the value.
3. If the SPI1.[MCSPI_IRQSTATUS](#)[0] TX0_EMPTY bit is set to 1, write 1 to it and return to Step 2 (polling method).

20.6.2.6.2.1.3 Read Operation

1. Read the SPI1.[MCSPI_IRQSTATUS](#)[2] RX0_FULL bit and if it is set to 1, go to Step 2.
2. If the SPI1.[MCSPI_IRQSTATUS](#)[2] RX0_FULL bit is set to 1, write 1 to it and return to Step 1 (polling method).

NOTE: Write and read operations can be performed simultaneously.

20.6.2.6.3 Programming in Interrupt Mode

This section follows the flow of [Figure 20-26](#).

1. Initialize software variables: WRITE_COUNT = 0 and READ_COUNT = 0.
2. Initialize interrupts: Write 0x7 in the SPI1.[MCSPI_IRQSTATUS](#)[3:0] field and set the SPI1.[MCSPI_IRQENABLE](#)[3:0] field to 0x7.
3. Follow the steps described in [Section 20.6.2.6.2.1.1, Mode Selection](#).
4. If WRITE_COUNT = w and READ_COUNT = w, write SPI1.[MCSPI_CHxCTRL](#)[0] = 0x0 (x = 0) to stop the channel.

This interrupt routine follows the flow of [Table 20-16](#) and [Figure 20-28](#).

1. Read the SPI1.[MCSPI_IRQSTATUS](#)[3:0] field.
2. If the SPI1.[MCSPI_IRQSTATUS](#)[0] TX0_EMPTY bit is set to 1:
 - (a) Write the command/address or data value in SPI1.[MCSPI_TXx](#) (where x = 0).
 - (b) WRITE_COUNT += 1
 - (c) Write SPI1.[MCSPI_IRQSTATUS](#)[0] = 0x1.
3. If the SPI1.[MCSPI_IRQSTATUS](#)[2] RX0_FULL bit is set to 1:
 - (a) Read SPI1.[MCSPI_RXx](#) (where x = 0)
 - (b) READ_COUNT += 1
 - (c) Write SPI1.[MCSPI_IRQSTATUS](#)[2] = 0x1

20.6.2.6.4 Operations for the Second Slave (on Channel 1) in Polling Mode

20.6.2.6.4.1 Mode Selection

The SPI1.[MCSPI_CHxCONF](#) register (with x = 1) allows configuration of the operating mode:

1. Set the SPI1.MCSPI_CH1CONF[18] IS bit to 0 for the spi1_somi pin in receive mode.
2. Set the SPI1.MCSPI_CH1CONF[17] DPE1 bit to 0 and the SPI1.MCSPI_CH1CONF[16] DPE0 bit to 1 for the spi1_somi pin in transmit mode.
3. Set the SPI1.MCSPI_CH1CONF[13:12] TRM field to 0x0 for transmit-and-receive mode.
4. Write 0x3 in the SPI1.MCSPI_CH1CONF[11:7] WL field.
5. Set the SPI1.MCSPI_CH1CONF[6] EPOL bit to 0 for spi1_cs1 activated high during the active state.
6. Set the SPI1.MCSPI_CH1CONF[1] POL bit to 1 for spi1_clk held low during the active state.
7. Set the SPI1.MCSPI_CH1CONF[0] PHA bit to 1 for data latched on even numbered edges of spi1_clk.

Clock Initialization and spi1_cs1 Enable

The SPI1.[MCSPI_MODULCTRL](#)[2] MS bit was set to 0 (providing the clock).

In master mode, the SPI must provide the clock and enable the channel:

8. Set the SPI1.MCSPI_CH0CTRL[0] EN bit to 0 to disable channel 0, and set the SPI1.MCSPI_CH1CTRL[0] EN bit to 1 to enable channel 1.

NOTE: Read and write operations for the second slave are identical to those for the first slave.

20.6.2.6.4.2 Write Operation

1. Write 1 to the SPI1.[MCSPI_IRQSTATUS](#)[4] TX1_EMPTY bit to reset the status.
2. Write the command/address or data value in the SPI1.MCSPI_TX1 register to transmit the value.
3. If the SPI1.[MCSPI_IRQSTATUS](#)[4] TX1_EMPTY bit is set to 1, write 1 to it and return to Step 2 (polling method).

20.6.2.6.4.3 Read Operation

1. Read the SPI1.[MCSPI_IRQSTATUS](#)[6] RX1_FULL bit and if it is set to 1, go to Step 2.
2. If the SPI1.[MCSPI_IRQSTATUS](#)[6] RX1_FULL bit is set to 1, write 1 to it and return to Step 1 (polling method).

NOTE: Write and read operations can be performed simultaneously.

20.6.3 Transfer Procedures with FIFO

In the subsections below, the transfer procedures are described with FIFO using ([MCSPI_CHxCONF](#)[27:28] FFER or/and FFEW = 1).

The MCSPI module allows the transfer of one or more words, according to different modes:

- Master normal, master turbo, slave
- Transmit-and-receive, transmit-only, receive-only
- Write and read requests: Interrupts, DMA

For these flows, the host process contains the main process and the interrupt routine, which is called on the IRQ signals or by an internal call if the module is used in polling mode.

20.6.3.1 Common Transfer Procedure

The common transfer sequence is the host sequence for a transfer of any type defined above.

In multichannel, only one channel can use the FIFO. Before enabling the FIFO for a channel (FFExW and FFExR bits in the [MCSPI_CHx_CONF](#) register), the host must ensure that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit/receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In slave mode, only channel 0 only can be activated. The correct spim_csx line is chosen in the MCSPI_CH0CONF register with the SPIENSLV bits.

The MCSPI module can start the transfer only when the first write request is released by writing the [MCSPI_TXx](#) register, even in receive-only mode (only one write request occurs in this case). [Figure 20-37](#) shows the main process of the common transfer sequence.

Figure 20-37. Common Transfer Sequence/Main Process

mcspi-041

The MCSPI module can start the transfer only after the first write request is released by writing the [MCSPI_TXx](#) register, even in receive-only mode (only one write request occurs in this case).

This first write request can be managed by the IRQ routine or DMA handler, as are as other requests. It appears in [Figure 20-37](#) to show this point.

The end of the transfer (dotted line in [Figure 20-37](#)) is more complex and depends on the transfer type. [Table 20-17](#) describes the different types of end-of-transfer and the transfer types to which they are applicable.

Table 20-17. End-of-Transfer Types

Word Count	Transmit/Receive	Transmit Only	Receive Only
Yes	See Section 20.6.3.2, Transmit-Receive With Word Count .	See Section 20.6.3.4, Transmit-Only .	See Section 20.6.3.5, Receive-Only With Word Count .
No	See Section 20.6.3.3, Transmit-Receive Without Word Count .	See Section 20.6.3.4, Transmit-Only .	See Section 20.6.3.6, Receive-Only Without Word Count .

The sequence differs depending on whether word count is used (MCSPI_XFERLEVEL: WCNT is set or not). The AEL and/or AFL values can be different, but they must be multiples of the word size in the FIFO: 1, 2, or 4 bytes, according to word length.

In these sequences, the transfer to execute has a size of N words.

When accessing the FIFO, only one word is written or read for each OCP access.

In these sequences, the number of words written or read for each write or read FIFO request is:

- `write_request_size`
- `read_request_size`

If they are not submultiples of N, the last request sizes are:

- `last_write_request_size (< write_request_size)`
- `last_read_request_size. (< read_request_size)`

The different sequences can be merged in one process to manage transfers of several types.

The end-of-transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- `write_count = N`
- `read_count = N`
- `last_request = FALSE`

They are initialized before starting the channel.

20.6.3.2 Transmit-Receive Procedure With Word Count (WCNT≠0)

[Figure 20-38](#) shows the flow of a transfer in transmit-receive mode, with word count.

Figure 20-38. Transmit-Receive With Word Count

mcspi-042

20.6.3.3 Transmit-Receive Procedure Without Word Count (WCNT=0)

Figure 20-39 shows the flow of a transfer in transmit-receive mode, without word count.

Figure 20-39. Transmit-Receive Without Word Count

mcspi-046

20.6.3.4 Transmit-Only Procedure

Figure 20-40 shows the flow of a transfer in transmit only mode, with our without word count.

Figure 20-40. Transmit-Only

mcspi-047

The difference between word count enabled or not is the condition after starting the channel:

- Word count enable: Wait for EOW interrupt.
- Word count disable: Wait for write_count = 0.

20.6.3.5 Receive-Only Procedure With Word Count (WCNT≠0)

Figure 20-41 shows the flow of a transfer in receive-only mode, with word count.

Figure 20-41. Receive-Only With Word Count

mcspi-045

20.6.3.6 Receive-Only Procedure Without Word Count (WCNT=0)

Figure 20-42 shows the flow of a transfer in receive-only mode, without word count.

Figure 20-42. Receive-Only Without Word Count

Type	RW		
Write Latency	Immediate		

Bits	Field Name	Description	Type	Reset
31:18	Reserved	Reads returns 0	RW	0x0000
17	EOW	End of word count event when a channel is enabled using the FIFO buffer and the channel had sent the number of SPI word defined by MCSPI_XFERLEVEL[31:16] WCNT bit field. Write 0x0: Event status bit unchanged. Read 0x0: Event false. Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
16	WKS	Wake-up event in slave mode when an active control signal is detected on the spim_csx line programmed in the MCSPI_CHxCONF[SPIENSLV] field (where x=0 only) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
15	Reserved	Reads returns 0.	RW	0x0
14	RX3_FULL	MCSPI_RX3 register is full (only when channel 3 is enabled) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
13	TX3_UNDERFLOW	MCSPI_TX3 register underflow (only when channel 3 is enabled) ⁽¹⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
12	TX3_EMPTY	MCSPI_TX3 register is empty (only when channel 3 is enabled) ⁽²⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
11	Reserved	Read returns 0.	RW	0x0
10	RX2_FULL	MCSPI_RX2 register full (only when channel 2 is enabled) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
9	TX2_UNDERFLOW	MCSPI_TX2 register underflow (only when channel 2 is enabled) ⁽¹⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
8	TX2_EMPTY	MCSPI_TX2 register empty (only when channel 2 is enabled) ⁽²⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false	RW	0x0

⁽¹⁾ The MCSPI_Tx register is empty (not updated by host or DMA with new data) before its time slot assignment.

Exception: No TX_UNDERFLOW event when no data has been loaded into the MCSPI_Tx register since channel has been enabled.

⁽²⁾ Enabling the channel automatically rises this event.

Bits	Field Name	Description	Type	Reset
		Write 0x1: Event status bit is reset. Read 0x1: Event is pending.		
7	Reserved	Read returns 0.	RW	0x0
6	RX1_FULL	MCSPI_RX1 register full (only when channel 1 is enabled) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
5	TX1_UNDERFLOW	MCSPI_TX1 register underflow (only when channel 1 is enabled) ⁽¹⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
4	TX1_EMPTY	MCSPI_TX1 register empty (only when channel 1 is enabled) ⁽³⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
3	RX0_OVERFLOW	MCSPI_RX0 register overflow (only in slave mode) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
2	RX0_FULL	MCSPI_RX0 register full (only when channel 0 is enabled) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
1	TX0_UNDERFLOW	MCSPI_TX0 register underflow (only when channel 0 is enabled) ⁽⁴⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
0	TX0_EMPTY	MCSPI_TX0 register empty (only when channel 0 is enabled) ⁽³⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0

⁽³⁾ Enabling the channel automatically rises this event.

⁽⁴⁾ The MCSPI_Txx register is empty (not updated by host or DMA with new data) before its time slot assignment.
Exception: No TX_UNDERFLOW event when no data has been loaded into the MCSPI_Txx register since channel has been enabled.

Description	This register is dedicated to the configuration of the channel x.		
Type	RW		
Write Latency	Immediate		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	CLKG	FFER	FFEW	TCS	SBPOL	SBE	Reserved	FORCE	TURBO	IS	DPE1	DPE0	DMAR	DMAW	TRM	WL		EPOL	CLKD		POL	PHA									

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Read returns 0s.	RW	0x00
29	CLKG	Clock divider granularity. This register defines the granularity of channel clock divider: power of two or one clock cycle granularity. When this bit is set, the MCSPI_CHxCTRL[15:8] EXTCLK bit field must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of MCSPI_CHxCONF[5:2] CLKD and EXTCLK values. 0x0: Clock granularity of power of two 0x1: One clock cycle granularity	RW	0x0
28	FFER	FIFO enabled for Receive. Only one channel can have this bit field set. 0x0: The buffer is not used to Receive data 0x1: The buffer is used to Receive data	RW	0x0
27	FFEW	FIFO enabled for Transmit. Only one channel can have this bit field set. 0x0: The buffer is not used to Transmit data 0x1: The buffer is used to Transmit data	RW	0x0
26:25	TCS	Chip select time control Defines the number of interface clock cycles between CS toggling and first (or last) edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles	RW	0x0
24	SBPOL	Start bit polarity 0x0: Start bit polarity is held to 0 during SPI transfer. 0x1: Start bit polarity is held to 1 during SPI transfer.	RW	0x0
23	SBE	Start bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer. Polarity is defined by MCSPI_CHxCONF[SBPOL] .	RW	0x0
22:21	Reserved	Write the reset value. Read returns the reset value.	RW	0x0
20	FORCE	Manual spim_csx assertion to keep spim_csx for channel x active between SPI words (single channel master mode only). The MCSPI_MODULCTRL[0] SINGLE bit must be set to 1.	RW	0x0

Bits	Field Name	Description	Type	Reset
		0x0: Writing 0 into this bit drives the spin_csx line low for channel x when MCSPI_CHxCONF [6] EPOL = 0, and drives it high when MCSPI_CHxCONF [6] EPOL = 1. 0x1: Writing 1 into this bit drives the spim_csx line high for channel x when MCSPI_CHxCONF [E6] EPOL = 0, and drives it low when MCSPI_CHxCONF [6] EPOL = 1.		
19	TURBO	Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer) 0x1: Turbo is activated to maximize the throughput for multi-SPI word transfers.	RW	0x0
18	IS	Input select 0x0: Data Line 0 (spim_somi) selected for reception 0x1: Data Line 1 (spim_simo) selected for reception	RW	0x1
17	DPE1	Transmission enable for data line 1 (spim_simo) 0x0: Data Line 1 (spim_simo) selected for transmission 0x1: No transmission on data Line 1 (spim_simo)	RW	0x1
16	DPE0	Transmission enable for data line 0 (spim_somi) 0x0: Data Line 0 (spim_somi) selected for transmission 0x1: No transmission on data Line 0 (spim_somi)	RW	0x0
15	DMAR	DMA Read request The DMA Read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. The DMA Read request line is deasserted on read completion of the receive register of the channel. 0x0: DMA read request disabled 0x1: DMA read request enabled	RW	0x0
14	DMAW	DMA Write request. The DMA write request line is asserted when the channel is enabled and the MCSPI_TXx register of the channel is empty. The DMA write request line is deasserted on load completion of the MCSPI_TXx register of the channel. 0x0: DMA write request disabled 0x1: DMA write request enabled	RW	0x0
13:12	TRM	Transmit/receive modes 0x0: Transmit and receive mode 0x1: Receive-only mode 0x2: Transmit-only mode 0x3: Reserved	RW	0x0
11:7	WL	SPI word length 0x0: Reserved 0x1: Reserved 0x2: Reserved 0x3: The SPI word is 4-bit long 0x4: The SPI word is 5-bit long 0x5: The SPI word is 6-bit long 0x6: The SPI word is 7-bit long 0x7: The SPI word is 8-bit long 0x8: The SPI word is 9-bit long 0x9: The SPI word is 10-bit long 0xA: The SPI word is 11-bit long	RW	0x00

Bits	Field Name	Description	Type	Reset
		0xB: The SPI word is 12-bit long 0xC: The SPI word is 13-bit long 0xD: The SPI word is 14-bit long 0xE: The SPI word is 15-bit long 0xF: The SPI word is 16-bit long 0x10: The SPI word is 17-bit long 0x11: The SPI word is 18-bit long 0x12: The SPI word is 19-bit long 0x13: The SPI word is 20-bit long 0x14: The SPI word is 21-bit long 0x15: The SPI word is 22-bit long 0x16: The SPI word is 23-bit long 0x17: The SPI word is 24-bit long 0x18: The SPI word is 25-bit long 0x19: The SPI word is 26-bit long 0x1A: The SPI word is 27-bit long 0x1B: The SPI word is 28-bit long 0x1C: The SPI word is 29-bit long 0x1D: The SPI word is 30-bit long 0x1E: The SPI word is 31-bit long 0x1F: The SPI word is 32-bit long		
6	EPOL	spim_csx polarity for channel x 0x0: spim_csx is held high during the active state. 0x1: spim_csx is held low during the active state.	RW	0x0
5:2	CLKD	Frequency divider for spim_clk (for master device only) A programmable clock divider divides the SPI reference clock (CLKSPIREF) by a 4-bit value and results in a new spim_clk clock available to shift data in and out. 0x0: 1 0x1: 2 0x2: 4 0x3: 8 0x4: 16 0x5: 32 0x6: 64 0x7: 128 0x8: 256 0x9: 512 0xA: 1024 0xB: 2048 0xC: 4096 0xD: 8192 0xE: 16384 0xF: 32768	RW	0x0
1	POL	spim_clk polarity 0x0: spim_clk is held high during the active state. 0x1: spim_clk is held low during the active state.	RW	0x0
0	PHA	spim_clk phase 0x0: Data are latched on odd-numbered edges of spim_clk. 0x1: Data are latched on even-numbered edges of spim_clk.	RW	0x0

7:6	Reserved	Read returns 0s.	RW	0x0
5:0	AEL	Buffer Almost Empty: This register holds the programmable almost empty level value used to determine almost empty buffer condition. If the user wants an interrupt or a DMA write request to be issued during a transmit operation when the data buffer is able to receive l bytes, then this bit field must be set to l-1. 0x0: One byte 0x1: 2 bytes 0x3E: 63 bytes 0x3F: 64 bytes	RW	0x00

Multichannel Buffered Serial Port

This chapter introduces the multichannel buffered serial port of the multimedia device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

21.5 McBSP Basic Programming Model	3148
21.6 McBSP Register Manual	3177

21.1 McBSP Overview

The multichannel buffered serial port (McBSP) provides a full-duplex direct serial interface between the device and other devices in a system such as other application chips (digital base band), audio and voice codec , etc. Because of its high level of versatility, it can accommodate to a wide range of peripherals and clocked frame oriented protocols (for details, see [Section 21.1.1](#)).

The device provides five instances of the McBSP module.

[Figure 21-1](#) shows the McBSP overview in the device.

Figure 21-1. McBSP Highlight

21.1.1 McBSP Features

The main features of the McBSP modules are:

- L4 interconnect slave interface supports:

- 32-bit data bus width
- 32-bit access supported
- 16- /8-bit access supported only by data registers
- 10-bit address bus width
- Burst mode not supported
- Write nonposted transaction mode supported
- 128 × 32-bit words (512 bytes) for each buffer for transmit/receive operations (McBSP1, 3, 4, 5)
- 5K bytes (1024 × 32 bits for audio buffer + 256 × 32 bits for buffer) for each buffer for transmit/receive audio operations (McBSP2 only)
- Interrupts configurable in legacy mode (2 requests) or PRCM compliant (1 request)
- Transmit and receive DMA requests triggered with programmable FIFO thresholds
- SIDETONE core support: Audio loopback capability (McBSP2 and 3 only)
- Multidrop support
- Serial interface description
 - 6 pin configuration (McBSP 1 only)
 - 4 pin configuration (McBSP2, 3, 4, 5)
 - Full-duplex communication
 - Multichannel selection modes
 - Support to enable or block transfers in each of the channels
 - 128 channels for transmission and for reception
 - Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices:
 - Inter-IC sound (I2S) compliant devices
 - Pulse code modulation (PCM) devices
 - Time division multiplexed (TDM) bus devices

CAUTION

McBSP modules do not offer support for µ-law and A-law companding, two partitions mode dynamic reassignment, AC'97, and SPI protocol.

- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
- Bit reordering (send/receive least significant bit [LSB])
- Clock and frame-synchronization generation support:
 - Independent clocking and framing for reception and for transmission up to 48 MHz
 - Support for external generation of clock signals and frame-synchronization (frame-sync) signals
 - A programmable sample rate generator for internal generation and control of clock signals and frame-sync signals
 - Programmable polarity for frame-sync pulses and for clock signals

NOTE:

- McBSP modules do not support features such as re-transmit or re-receive of an erroneous frame or word.
- McBSP modules support dual phase frames to provide I2S fully compliant capabilities. But, this dual phase mode is limited at one channel (or word) for each phase instead of 128 channels max for single phase mode.

21.1.2 SIDETONE Core

The purpose of this section is to present the SIDETONE core implemented in McBSP2 and 3 modules. It is required that two of the audio input channels to be looped back, filtered, and mixed to the two corresponding audio output channels.

Data to be processed comes on two separate paths (one for each channel) through a simple interface. After filtering the data, gain is applied and outputted through a similar interface. For more details, see [Figure 21-2](#).

Figure 21-2. SIDETONE Core Architecture

mcbsp-002

The SIDETONE core offers the following features:

- Filter coefficients are shared between the two channels (the filter coefficient is assumed to represent values in the range $-1\dots+1$)
- Gains are independent for the two channels (the gain coefficients are in the range $-2\dots+2$)
- The filter output is multiplied with the gain, and the result is rounded to output channel word width.
- The FIR filter length is 128 samples.
- Filtered loop back signals are added to the corresponding output signals, and saturation is applied if the result exceeds arithmetic range.
- Filter coefficients and gains are programmable:
 - Coefficients are changed while audio is stopped.
 - Gains are changed at any time (also during audio operation with SIDETONE enabled).

21.2 McBSP Environment

This section describes the intended functions for McBSP module from an environment point of view (that is, external connections). It presents the McBSP connectivity options, lists the possible interfaces, and details the protocol and data format used in each case.

21.2.1 McBSP Functions

The device provides five instances of the McBSP module, called McBSP1, McBSP2, McBSP3, McBSP4, and McBSP5.

List of recommended usage (non exhaustive) per McBSP modules in the device:

- McBSP1: Digital baseband (DBB) data
- McBSP2: Audio data with audio buffer and SIDETONE feature
- McBSP3: Bluetooth® voice data with SIDETONE feature
- McBSP4: DBB voice data
- McBSP5: Midi data

[Table 21-1](#) describes the functions and the corresponding application fields.

Table 21-1. Functions Description

Function	Application Field	Recommended McBSP module	Description
Control and Data	Digital Base Band (DBB) Data	McBSP1	Serial interface to transfer data
Audio Data	Audio Data with Audio Buffer	McBSP2	Audio interface to transfer audio data with Inter-IC Sound codec (I2S)
	Audio Data with Audio Buffer and SIDETONE feature		
	Midi Data	McBSP5	
Voice Data	Bluetooth Voice Data	McBSP3	Voice interface to transfer voice data with Pulse Code Modulation codec (PCM)
	Bluetooth Voice Data with SIDETONE feature		
	DBB Voice Data	McBSP4	

21.2.2 McBSP Signals Descriptions

The five McBSP modules consist of a data-flow path and a control path connected to external devices by a serial interface with 6-pin configuration (McBSP 1 only) or 4-pin configuration (McBSP2, 3, 4, 5).

For a McBSP module with 6-pin configuration, an internal loopback capability between transmitter and receiver clock signals, and both frame-synchronization signals enables using the McBSP module with 4-pin configuration. The related internal multiplexers are controlled through the system control module on the device (see [Section 21.3](#)).

Table 21-2. Input/Output Description

Pin Name ⁽¹⁾	I/O ⁽²⁾	Description	Internal Signal Name	Reset Value	Control and Data	Audio Data	Voice Data
mcbsp_clks	I	External clock (shared by all McBSP modules)	CLKS	-	✓	✓	✓
mcbspi_dr	I	Receive serial data	DR	-	✓	✓	✓
mcbspi_dx	I/O ⁽³⁾	Transmit serial data	DX	0	✓	✓	✓
mcbspi_clkx	I/O ⁽³⁾	Transmit clock ⁽⁴⁾	CLKX	0	✓	✓	✓
mcbspi_fsx	I/O ⁽³⁾	Transmit frame synchronization ⁽⁵⁾	FSX	0	✓	✓	✓
mcbsp1_clkx	I/O ⁽³⁾	Receive clock ⁽⁶⁾	CLKR	1	✓		
mcbsp1_fsr	I/O ⁽³⁾	Receive frame synchronization ⁽⁷⁾	FSR	0	✓		

⁽¹⁾ I = 1 to 5⁽²⁾ I = Input; O = Output⁽³⁾ For details of the input/output selection, see [Section 21.2.3.1](#).⁽⁴⁾ This signal is also used as CLKR when it is configured as output (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to1).⁽⁵⁾ This signal is also used as FSR when it is configured as output (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to1).⁽⁶⁾ This signal is also used as CLKX when it is configured as input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to1).⁽⁷⁾ This signal is also used as FSX when it is configured as input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to1).

- The mcbsp_clks pin can be used to inject an external clock. This clock is used to generate control signals depending on the module internal configuration (see [Section 21.4.3, McBSP SRG](#)). The CLKS signal of the McBSP modules is linked to an external signal through the mcbsp_clks pin, but the CLKS signal can also be linked to an internal clock provided by PRCM of the device. For more information, see [Section 21.3, McBSP Integration](#).
- Data are transmitted to external devices interfacing with McBSP modules via the mcbspi_dx pin. Data from those devices are received on the mcbspi_dr pin.

NOTE: The mcbspi_dx pin is an input/output signal to use the McBSP module in half-duplex mode.

- Control information is communicated through the following pins: mcbspi_clkx (transmit clock), mcbsp1_clkx (receive clock), mcbspi_fsx (transmit frame-sync), and mcbsp1_fsr (receive frame-sync).

CAUTION

External pins mcbsp1_clkx and mcbsp1_fsr are connected to pads only for McBSP1 module; other McBSP modules don't have these connections. For these modules, CLKR and FSR signals sources are mcbspi_clkx and mcbspi_fsx pins, respectively. Consequently, there is a light restriction on other McBSP modules when used in full-duplex mode. Reception and transmission use the same clock signal and the same frame synchronization signal.

21.2.3 McBSP Functions Description

21.2.3.1 McBSP Modes

For all McBSP functions, McBSP modules can operate in master or slave mode. The difference between these modes is the definition of the source of McBSP clocks and McBSP frames synchronization:

- Master mode: McBSP module provides them to the external device

- Slave mode: McBSP module receives them from the external device

The choice between the two modes depends of technical data of the external device and the type of interface (protocols and data formats). For one McBSP module, there are four possible functions:

1. Transmit and receive master mode
2. Transmit and receive slave mode
3. Transmit master mode and receive slave mode
4. Transmit slave mode and receive master mode

NOTE: If the McBSP module has a serial interface with 4-pin configuration (McBSP2, 3, 4, 5), only modes 1 and 2 are possible.

[Figure 21-3](#) shows the connection between the McBSP1 module (6-pin configuration) and an external device in transmit master mode and receive slave mode.

Figure 21-3. Mode Overview of McBSP1 Module

[Figure 21-4](#) shows the connection between the McBSP*i* module, with $i = 2, 3, 4$ or 5 (4-pin configuration) and an external device in transmit and receive master mode.

Figure 21-4. Mode Overview of McBSPi Module

21.2.3.2 McBSP Functions

21.2.3.2.1 McBSP Function 1: Control and Data

In full-duplex mode (reception and transmission use independent clock signals and frame-synchronization signals), the McBSP module can be used to exchange control and data with an external chipset, allowing the device to be interfaced with a modem device. [Figure 21-5](#) shows typical connections between device and modem chipset to illustrate the DBB data application.

Figure 21-5. DBB Data Application

In [Figure 21-5](#), the McBSP1 module is configured in transmit master mode and in receive slave mode.

21.2.3.2.2 McBSP Function 2: Audio Data

The McBSP module is connected to audio devices through the I₂S™ interface. The I₂S link serial interface is a TDM slot based serial interface that is used to transfer audio data. Those audio devices can be either AICs or other serially connected A/D and D/A devices.

[Figure 21-6](#) shows typical connections between device and a typical device of analog audio interface (TPS65950 device) to illustrate the audio data application. The typical device contains several audio analog inputs and outputs, as well as digital microphone inputs.

Figure 21-6. Audio Data Application

In [Figure 21-6](#), the McBSP2 module is configured in transmit and receive master modes.

21.2.3.2.3 McBSP Function 3: Voice Data

The McBSP module is connected to a voice device through the PCM interface. The PCM link serial interface is a TDM slot based serial interface that is used to transfer voice data. The voice devices can be modem chipsets, Bluetooth chipsets, or other devices with voice data interface.

[Figure 21-7](#) shows typical connections between the device and Bluetooth chipset (TI BRF6300 or TI BRF6350) to illustrate voice data application.

Figure 21-7. Voice Data Application

In [Figure 21-7](#), the McBSP3 module is configured in transmit and receive master modes.

21.2.4 McBSP Protocols and Data Formats

The McBSP module can use one of the three protocols with associated data formats:

- Serial protocol to exchange serial data
- Audio protocol to exchange the audio samples
- Voice protocol to exchange the voice samples

The McBSP modules offer the flexibility to modify the following parameters to adapt to the device features as described in the following subsections.

21.2.4.1 Word, Frame, and Phase Definitions

21.2.4.1.1 Words or Channels

The data bits are transferred (transmission or reception) in a group called a serial word or channel. The number of bits in a word (length) is programmable via bits field (McBSPi.[MCBSPLP_RCR1_REG\[7:5\]](#) RWDLEN1 field and McBSPi.[MCBSPLP_RCR2_REG\[7:5\]](#) RWDLEN2 field, McBSPi.[MCBSPLP_XCR1_REG\[7:5\]](#) XWDLEN1 bit field and McBSPi.[MCBSPLP_XCR2_REG\[7:5\]](#) XWDLEN2 bit field) and can be 8, 12, 16, 20, 24, or 32 bits (see [Section 21.4.2.3, Clocking and Framing Data](#)). The McBSP module uses clock signals to control the time for each bit transfer. Data are sampled/driven on rising or falling edge of clock signals. This clock polarity is programmable through the bit fields of the pin-control register (McBSPi.[MCBSPLP_PCR_REG](#)).

For more information, see [Section 21.4.2.4, Frame Phases \(Dual-Phase Frame I2S Support\)](#).

21.2.4.1.2 Frames

One or more words (maximum 128) are transferred in a group called a frame. The McBSP module can transmit/receive a maximum of 128 words per frame, programmable through the bit fields of the transmit and receive control registers (McBSPi.[MCBSPLP_XCR1_REG](#)/McBSPi.[MCBSPLP_XCR2_REG](#) and McBSPi.[MCBSPLP_RCR1_REG](#)/McBSPi.[MCBSPLP_RCR2_REG](#)). For more details, see [Section 21.4.2.3, Clocking and Framing Data](#).

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-synchronization signals to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on. Frame-synchronization pulse is active high or low. This pulse polarity is programmable via bits field of pin-control register (McBSPi.[MCBSPLP_PCR_REG](#)).

Each frame transfer can be delayed by 0, 1, or 2 clock cycles, depending on the value of the bits for the transmit and receive control registers (McBSPi.[MCBSPLP_XCR2_REG](#) and McBSPi.[MCBSPLP_RCR2_REG](#)). For more information, see [Section 21.4.4.3.3, Preventing Unexpected Receive Frame-sync Pulses](#) and [Section 21.4.4.6.3, Preventing Unexpected Transmit Frame-Sync Pulses](#).

21.2.4.1.3 Phases

The McBSP module allows configuring each frame to contain one or two phases. The McBSP module supports dual-phase frames to provide I2S fully compliant capabilities. These two phases represent left and right channels of audio stereo signals.

The limitation on dual-phase frame is that the number of words per phase must be set to 1 for both first and second phases. But, the number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers.

For example, software can define a frame composed of a first phase with one 12-bit word and a second phase with one 16-bit word. This configuration allows the software to compose frames for custom applications. For more details, see [Section 21.4.2.4, Frame Phases \(Dual-Phase Frame I2S Support\)](#).

[Figure 21-8](#) shows signal activity for two possible reception/transmission scenarios.

Figure 21-8. McBSP Reception/Transmission Signal Activity

21.2.4.2 Serial Protocol and Data Formats

21.2.4.2.1 Protocol

The serial protocol is used to send and receive control data without specific formats. This allows McBSP module to accommodate all serial devices and their protocols.

21.2.4.2.2 Data Format

Figure 21-9 shows the typical operation of the McBSP clock and frame sync signals. Serial clocks CLKR and CLKX define the boundaries between bits for receive and transmit, respectively. Similarly, frame-sync signals FSR and FSX define the beginning of an element and/or frame transfer. The McBSP module allows the configuration of the following parameters for data and frame synchronization:

- Polarity of FSR, FSX, CLKX, and CLKR
- The number of words per frame
- The number of bits per word
- Whether subsequent frame synchronization restarts the serial data stream or is ignored
- The data delay from frame synchronization to first data bit which can be 0-, 1-, or 2-bit delays

The configuration is independent for receive and transmit parts. For more details and configuration examples, see [Section 21.4, McBSP Functional Description](#) and [Section 21.5, McBSP Basic Programming Model](#).

Figure 21-9. Serial Data Formats

21.2.4.3 Audio Protocol and Data Formats

21.2.4.3.1 Protocol

The I2S protocol is used to send and receive audio data from 8-kHz to 48-kHz sampling rate (frame-sync frequency), with 16 bits or 32 bits per words (supported frequencies are 8, 11.025, 12, 16, 22.05, 24, 32, 44.1, and 48 kHz).

The frame-synchronization signal defines the frame length in the I2S protocol. Each frame consists of a fixed number of words. In dual-phase frame, the frame-synchronization signal is low for the left phase time slot and high for the right phase time slot. In addition, the frame-synchronization signal is synchronous to the falling edge of the clock signal.

21.2.4.3.2 Data Formats

The I2S protocol supports TDM, I2S, left-justified, and right-justified data formats.

Bits of each word (sample) are clocked using the clock signal. For each word, the MSB is first. LSBs are padded to 0 when the data length (8, 12, 16, 20, or 24 bits) is less than the sample word width (16 or 32 bits).

21.2.4.3.2.1 TDM Data Format

Figure 21-10 shows that each frame of TDM data format is composed of four words (or channels).

Figure 21-10. TDM Data Format; Word Width: 32 Bits; Data Length: 24 Bits

21.2.4.3.2.2 I2S Data Format

Figure 21-11 shows an example with 24-bit data (MSB first) and 8 padding bits at 0.

Figure 21-11. I2S Data Format; Word Width: 32 Bits; Data Length: 24 Bits

mcbsp-011

21.2.4.3.2.3 Left-Justified Data Format

Figure 21-12 shows an example with 24-bit data (MSB first) and 8 padding bits at 0.

Figure 21-12. Left-Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits

mcbsp-012

21.2.4.3.2.4 Right-Justified Data Format

Figure 21-13 shows an example with 8 padding bits at '0' and 24 bits data (MSB first).

Figure 21-13. Right-Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits

mcbsp-013

21.2.4.4 Voice Protocol and Data Formats

21.2.4.4.1 Protocol

The PCM protocol is intended to transfer voice data at 8-kHz (default narrowband mode) or 16-kHz (wideband mode) sample rates (frame-sync frequency). PCM protocol can act as a slave or master, and is used by the Bluetooth interface and the modem generic interface. The frame-synchronization defines the frame length in the PCM protocol. Bits are clocked using the PCM clock signal, with the MSB first.

21.2.4.4.2 Data Formats

Two modes are available for the PCM protocol: mode 1 and mode 2. For both modes, there are two types of operation: mono and stereo channels. The difference between PCM mode 1 and PCM mode 2 is in the way they use either the rising or the falling edge of the clock signal, and the frame-synchronization polarity.

- PCM Mode 1: Input data is latched on the falling edge of the clock, and the transmitted data starts on the rising edge of the clock. Frame-synchronization pulse is active high.
- PCM Mode 2: Input data is latched on the falling edge of the clock, and the transmitted data starts on the falling edge of the clock. Frame-synchronization pulse is active low.

[Figure 21-14](#) and [Figure 21-15](#) shows an example of PCM protocol, mode 1 and mode 2, respectively, for a frame composed one word (width: 32 bits) with 16 bits data.

Figure 21-14. PCM Protocol – Mode 1 Data Format

Figure 21-15. PCM Protocol – Mode 2 Data Format

21.3 McBSP Integration

This section describes the McBSP modules integration inside the device and all the details about signal source controls, clocks, resets, power management, and hardware requests.

McBSP modules are divided into two families: McBSP modules that are gated in the CORE domain (McBSP1 and 5), and McBSP modules that are gated in the PER domain (McBSP2, 3, and 4).

For more details on the CORE and PER domains, see [Chapter 3, Power, Reset and Clock Management](#).

[Figure 21-16](#) through [Figure 21-20](#) show the integration of the McBSP modules in the device, including interrupt handlers, DMA requests, clock generators, and interconnections.

Figure 21-19. McBSP4 Integration

Figure 21-20. McBSP5 Integration

21.3.1 Signal Source Control

The FSR, CLKR, and CLKS signal sources are defined by the system control module. The control registers of the system control module are used to select these signal sources.

21.3.1.1 McBSP1 Module (6-Pin Configuration)

The MCBSP1_CLKS bit of the CONTROL.CONTROL_DEVCONF0[2] register is used to select the McBSP1 module CLKS signal source:

- When set to 0, the CLKS source is from the CORE_96M_FCLK.
- When set to 1, the CLKS source is from the mcbsp_clks pin.

The MCBSP1_CLKR bit of the CONTROL_DEVCONF0[3] register is used to select the McBSP1 module CLKR signal source:

- When set to 0, the CLKR source is from the CLKR input signal.
- When set to 1, the CLKR source is from the CLKX input signal.

The MCBSP1_FSR bit of the CONTROL_DEVCONF0[4] register is used to select the McBSP1 module FSR signal source:

- When set to 0, the FSR source is from the FSR input signal.
- When set to 1, the FSR source is from the FSX input signal.

21.3.1.2 McBSP2, 3, 4, and 5 Modules (4-Pin Configuration)

For these McBSPi modules, there are no external mcbspi_clk and mcbspi_fxr pins (where I = 2, 3, 4, and 5).

Consequently, the system control module controls only the internal connection of CLKS input signals. The settings are explained in [Section 21.3.2.2.2](#), [Section 21.3.2.2.3](#), [Section 21.3.2.2.4](#), and [Section 21.3.2.2.5](#).

21.3.2 Clocking, Reset, and Power Management Scheme

21.3.2.1 Power Domain

The McBSP1 and McBSP5 modules belong to the CORE domain, whereas the McBSP2, McBSP3, and McBSP4 modules belong to the PER (peripheral) domain. This separation of the McBSP modules into two power domains allows the major part of the device to be switched off while keeping McBSP2, 3, and 4 active.

For more information about these power domains, see [Chapter 3, Power , Reset, and Clock Management](#).

21.3.2.2 Clocks

There are two clock domains in the McBSP module:

- Functional clock domain
- Interface clock domain

Table 21-3. Clocking Signals Input to McBSP Module

Type	Name	Source	Description
Interface	McBSPi_ICLK	PER_L4_ICLK (McBSP2, 3, 4) ⁽¹⁾	The L4 interface clock is used for the module internal L4 interconnect slave interface and all depending parts of the Interface clock domain.
		CORE_L4_ICLK (McBSP1, 5) ⁽¹⁾	
Functional	CLKS	PER_96M_FCLK (McBSP2, 3, 4) ⁽¹⁾	McBSP module is running using either a functional clock generated internally (master mode) or supplied from its serial interface (slave mode) for the internal logic. Internal registers select the source of the functional clock and the divider ratio to apply.
		CORE_96M_FCLK (McBSP1, 5) ⁽¹⁾	
		mcbsp_clks (external source common to all McBSP modules)	
Functional	CLKX	mcbspi_clkx (external source)	Functional clock after division in any mode is limited to maximum frequency divided by 2.
Functional	CLKR (McBSP1 only)	mcbsp1_clkr (external source)	

⁽¹⁾ For more information about these sources, see [Chapter 3, Power, Reset, and Clock Management](#).

21.3.2.2.1 McBSP1 Clocks

The McBSP1 module is clocked by a functional clock (CLKS, CLKX, or CLKR) and an interface clock (McBSP1_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP1 module, the functional clock comes from the CLKS signal, CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP1.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP1.MCBSPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP1 module is linked to an internal clock (CORE_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbsp_clks pin of the device boundary. The MCBSP1_CLKS bit of the CONTROL.CONTROL_DEVCONF0[2] register is used to select the McBSP1 module CLKS signal source:

- 0: The CLKS source is from the CORE_96M_FCLK.
- 1: The CLKS source is from the mcbsp_clks pin.

For more information on this register, see [Chapter 13, System Control Module](#).

NOTE: When the McBSP1 module no longer requires the PRCM functional clock, software can disable it at the PRCM level by setting the EN_MCBSP1 bit (PRCM.CM_FCLKEN1_CORE[9]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

At PRCM level, when all the conditions to shut-off CORE_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP1 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP1. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

The CLKX and CLKR signals are connected by the mcbsp1_clkx or mcbsp1_clkr pads. These signals are used like functional clocks by the intermediary of the sample rate generator (SRG).

- The McBSP1_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP1 L4 interface and McBSP1 configuration interface through the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP SRG (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is the CORE_L4_ICLK signal.

NOTE: When the McBSP1 module no longer requires the interface clock, software can disable it at the PRCM level by setting the EN_MCBSP1 bit (PRCM.CM_ICLKEN1_CORE[9]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

At the PRCM level, when all the conditions to shut off the CORE_L4_ICLK clock are met, the PRCM module automatically launches a hardware handshake protocol to ensure McBSP1 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP1. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE1_CORE[9] register AUTO_MCBSP1 bit set to 1). In this case, McBSP1_ICLK follows the CORE_L4 clock domain behavior on the device. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

21.3.2.2.2 McBSP2 Clocks

The McBSP2 module is clocked by a functional clock (CLKS, CLKX or CLKR) and an interface clock (McBSP2_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP2 module, the functional clock comes from the CLKS signal CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP2.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP2.MCBSPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP2 module is linked to an internal clock (PER_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbsp_clks pin of the device boundary. The MCBSP2_CLKS bit of the CONTROL.CONTROL_DEVCONF0[6] register is used to select the McBSP2 module CLKS signal source:

- 0: The CLKS source is from the PER_96M_FCLK.
- 1: The CLKS source is from the mcbsp_clks pin.

For more information, see [Chapter 13, System Control Module](#).

NOTE: When the McBSP2 module no longer requires the functional clock, software can disable it at the PRCM level by setting the EN_MCBSP2 bit (PRCM.CM_FCLKEN_PER[0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

At the PRCM level, when all the conditions to shut off the PER_96M_FCLK clock are met, the PRCM module automatically launches a hardware handshake protocol to ensure McBSP2 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP2. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

Only, the CLKX signal is connected by mcbsp2_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of the SRG.

- The McBSP2_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP2 L4 interface and McBSP2 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is the PER_L4_ICLK signal.

NOTE: When the McBSP2 module no longer requires the interface clock, software can disable it at the PRCM level by setting the EN_MCBSP2 bit (PRCM.CM_ICLKEN_PER[0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

At the PRCM level, when all the conditions to shut-off PER_L4_ICLK clock are met, the PRCM module automatically launches a hardware handshake protocol to ensure McBSP2 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP2. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[0] register AUTO_MCBSP2 bit set to 1). In this case, McBSP2_ICLK follows the CORE_L4 clock domain behavior on the device. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

21.3.2.2.3 McBSP3 Clocks

The McBSP3 module is clocked by a functional clock (CLKS, CLKX or CLKR) and an interface clock (McBSP3_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP3 module, the functional clock comes from the CLKS signal CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP3.MCBSPPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP3.MCBSPPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP3 module is linked to an internal clock (PER_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbsp_clks pin of the device boundary. The MCBSP3_CLKS bit of the CONTROL.CONTROL_DEVCONF1[0] register is used to select the McBSP3 module CLKS signal source:

- 0: The CLKS source is from the PER_96M_FCLK.
- 1: The CLKS source is from the mcbsp_clks pin.

For more information, see [Chapter 13, System Control Module](#).

NOTE: When the McBSP3 module no longer requires the functional clock, software can disable it at the PRCM level by setting the EN_MCBSP3 bit (PRCM.CM_FCLKEN_PER[1]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

At the PRCM level, when all the conditions to shut off the PER_96M_FCLK clock are met, the PRCM module automatically launches a hardware handshake protocol to ensure McBSP3 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP3. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

Only, the CLKX signal is connected by mcbsp3_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP3_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP3 L4 interface and McBSP3 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is the PER_L4_ICLK signal.

NOTE: When the McBSP3 module no longer requires the interface clock, software can disable it at the PRCM level by setting the EN_MCBSP3 bit (PRCM.CM_ICLKEN_PER[1]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

At the PRCM level, when all the conditions to shut off the PER_L4_ICLK clock are met, the PRCM module automatically launches a hardware handshake protocol to ensure McBSP3 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP3. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[1] register AUTO_MCBSP3 bit set to 1). In this case, McBSP3_ICLK follows the PER_L4 clock domain behavior on the device. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

21.3.2.2.4 McBSP4 Clocks

The McBSP4 module is clocked by a functional clock (CLKS or CLKX) and an interface clock (McBSP4_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP4 module, the functional clock comes from the CLKS signal, the CLKX signal, or the CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP4.MCBSPPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP4.MCBSPPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP4 module is linked to an internal clock (PER_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbsp_clks pin of the device boundary. The MCBSP4_CLKS bit of the CONTROL.CONTROL_DEVCONF1[2] register is used to select the McBSP4 module CLKS signal source:

- 0: The CLKS source is from the PER_96M_FCLK.
- 1: The CLKS source is from the mcbsp_clks pin.

For more information, see [Chapter 13, System Control Module](#).

NOTE: When the McBSP4 module no longer requires the functional clock, software can disable it at the PRCM level by setting the EN_MCBSP4 bit (PRCM.CM_FCLKEN_PER[2]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

At the PRCM level, when all the conditions to shut off the PER_96M_FCLK clock are met, the PRCM module automatically launches a hardware handshake protocol to ensure McBSP4 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP4. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

Only the CLKX signal is connected by mcbsp4_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP4_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP4 L4 interface and McBSP4 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is the PER_L4_ICLK signal.

NOTE: When the McBSP4 module no longer requires the interface clock, software can disable it at the PRCM level by setting the EN_MCBSP4 bit (PRCM.CM_ICLKEN_PER[2]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

At the PRCM level, when all the conditions to shut off the PER_L4_ICLK clock are met, the PRCM module automatically launches a hardware handshake protocol to ensure McBSP4 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP4. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[2] register AUTO_MCBSP4 bit set to 1). In this case, McBSP4_ICLK follows the PER_L4 clock domain behavior on the device. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

21.3.2.2.5 McBSP5 Clocks

The McBSP5 module is clocked by a functional clock (CLKS or CLKX) and an interface clock (McBSP5_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP5 module, the functional clock comes from the CLKS signal, the CLKX signal, or the CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP5.MCBSPPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP5.MCBSPPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP5 module is linked to an internal clock (CORE_96M_FCLK) provided by PRCM. The CLKS signal can also be linked to an external signal through the mcbsp_clks pin of the device boundary. The MCBSP5_CLKS bit of the CONTROL.CONTROL_DEVCONF1[4] register is used to select the McBSP5 module CLKS signal source:

- 0: The CLKS source is from the CORE_96M_FCLK.
- 1: The CLKS source is from the mcbsp_clks pin.

For more information, see [Chapter 13, System Control Module](#).

NOTE: When the McBSP5 module no longer requires the functional clock, software can disable it at the PRCM level by setting the EN_MCBSP5 bit (PRCM.CM_FCLKEN1_CORE[10]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

At the PRCM level, when all the conditions to shut off the CORE_96M_FCLK clock are met, the PRCM module automatically launches a hardware handshake protocol to ensure McBSP5 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP5. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

Only, the CLKX signal is connected by mcbsp5_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP5_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP5 L4 interface and McBSP5 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is the CORE_L4_ICLK signal.

NOTE: When the McBSP5 module no longer requires the interface clock, software can disable it at the PRCM level by setting the EN_MCBSP5 bit (PRCM.CM_ICLKEN1_CORE[10]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

At the PRCM level, when all the conditions to shut off the CORE_L4_ICLK clock are met, the PRCM module automatically launches a hardware handshake protocol to ensure McBSP5 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP5. For more details, see [Chapter 3, Power, Reset, and Clock Management](#).

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE1_CORE[10] register AUTO_MCBSP5 bit set to 1). In this case, McBSP5_ICLK follows the CORE_L4 clock domain behavior on the device. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

21.3.2.2.6 SIDETONE Clock

The SIDETONE feature, in the McBSP2 and McBSP3 modules, is clocked only by an interface clock (McBSP2_ICLK or McBSP3_ICLK).

CAUTION

See [Section 21.3.2.2](#) and [Section 21.3.2.3](#) for information on McBSP2_ICLK and McBSP3_ICLK clocks.

When the SIDETONE feature no longer requires the clock, software can disable it at the SIDETONE level by setting the McBSPi.[ST_SYSConfig_REG\[0\]](#) AUTOIDLE bit in SIDETONE registers. To conserve power, when SIDETONE feature is not active or there is no activity on SIDETONE feature, the McBSPi_ICLK clock supports an automatic gating that is enabled or disabled by setting the McBSPi.[ST_SYSConfig_REG\[0\]](#) AUTOIDLE bit.

- When this bit is asserted (set to 1), the McBSPi_ICLK clock auto-gating is enabled and this clock is disabled internally to the SIDETONE feature, thus reducing power consumption, but not to the McBSP module that contains this feature.
After reset, the automatic clock gating is enabled; thus, this bit must be disabled by software for activated SIDETONE feature.
- When this bit is set to 0, the McBSPi_ICLK clock auto-gating is disabled and this clock is enabled. The SIDETONE feature can be used normally.

21.3.2.3 Hardware and Software Reset

McBSP1 and McBSP5 modules belong to the CORE domain and their reset signal is the CORE_RST signal from the PRCM module, whereas McBSP2, 3 and 4 modules belong to the PER domain and their reset signal is the PER_RST signal from the PRCM module.

For more details about these signals, see [Chapter 3, Power, Reset, and Clock Management](#).

Table 21-4. Software Reset Signals to All McBSP Modules

Type	Bit Field	Register Source	Activation	Description
Software	SOFTRESET	MCBSPi.MCBSPPLP_SYSCONFIG_REG[1]	Active high	McBSP global software reset
	RRST	MCBSPi.MCBSPPLP_SPCR1_REG[0]		This resets and disables the receiver, including the RB.
	XRST	MCBSPi.MCBSPPLP_SPCR2_REG[0]		This resets and disables the transmitter, including the XB.
	GRST	MCBSPi.MCBSPPLP_SPCR2_REG[6]		SRG is reset
	FRST	MCBSPi.MCBSPPLP_SPCR2_REG[7]		Frame-sync logic is reset. Frame-sync generated signal is not generated by the SRG

For more details about these signals, see [Section 21.6, McBSP Register Manual](#). See [Section 21.5.1.1, McBSP Initialization Procedure](#), for a complete description of the McBSP initialization procedure.

21.3.2.4 Power Management

21.3.2.4.1 McBSP Operating States

Two operating states are defined for all the McBSP modules:

- ACTIVE state: The module is running synchronously on the interface and functional clock, interrupts and DMA requests can be generated according to the configuration (register, master or slave mode, etc) and the external signals.
- IDLE state: As part of the system power management, the PRCM module can request the McBSP modules to enter IDLE state. Depending on the configured acknowledgment mode: Force Idle, No Idle and Smart Idle modes, a McBSP module will effectively enter IDLE state or not. As soon as a McBSP module enters IDLE state, it doesn't have anymore activities except those unrelated to clock activity (for example wake-up features) and its clocks are likely to be switched off at PRCM level.

When the McBSP goes into IDLE state, the McBSP internal state-machine clock switches from interface clock (L4_ICLK) to external serial clock (because OMAP is supposed to shut down all internal clocks). Then the McBSP can continue to process during IDLE state with the external clock provided by the external component/AUDIOBUFFER.

The McBSP can exit IDLE state only if the external serial clock is active. After exiting IDLE state, McBSP state-machine clock is provided by the OMAP interface clock (L4_ICLK).

NOTE: Idle request and idle acknowledge are only internal signals, with no means to observe or to control. The signals generation and control is purely hardware (managed automatically by the PRCM and the McBSP module depending on the SIDLEMODE settings).

21.3.2.4.2 McBSP Acknowledgment Modes

During initialization or configuration of the McBSP module, the software must configure how the McBSP module will answer an IDLE solicitation from the PRCM module (that is, the way idle acknowledge will be asserted following an idle request assertion).

Each McBSP module can be configured via the MCBSPi.MCBSPPLP_SYSCONFIG_REG[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- Force Idle mode (SIDLEMODE bit = 0x0): An idle request is acknowledged unconditionally, regardless of the internal state of the module. The McBSP module immediately enters Idle state (no activity), interface and PRCM functional clock can be stopped, no interrupts and DMA requests can be generated. In this mode, the McBSP module freezes all the internal activity when the PRCM clocks are switched off by the PRCM module, leading to a potential loss of data.

CAUTION

In Force Idle mode, the wake-up feature is inhibited.

CAUTION

If the McBSP functional part, transmitter or receiver, is running within this period of time (the functional clock source is not the PRCM functional clock), the internal state of the McBSP module will not be idle (FSM states, processes, etc.), and when the McBSP module exits from the Force Idle state unexpected behavior may happen in both receiver and transmitter. To avoid this, both receive and transmit parts, must be disabled by software prior to idle request assertion (all functional clock external sources must be disabled).

- No Idle mode (SIDLEMODE bit = 0x1): An idle request is never acknowledged, meaning it will prevent the PRCM from switching off its related clocks and from putting in a lower power state than the power domain it belongs to. The McBSP module never enters Idle state (is active).
- Smart Idle mode (SIDLEMODE bit = 0x2): Acknowledgment to an idle request is given based on the internal activity of the McBSP module. The McBSP module is in a waiting state, interface / functional clocks can be stopped, no interrupt can be generated, a wake-up signal can be generated according to the configuration (See [Section 21.3.2.4.4](#)) and external signals.

NOTE: The value `MCBSPi.MCBSPPLP_SYSCONFIG_REG[4:3]` SIDLEMODE field = 0x3 must not be used.

When configured in Smart Idle mode, McBSP module also offers an additional granularity on `MCBSPi_FCLK` and `MCBSPi_ICLK` gating. `MCBSPi.MCBSPPLP_SYSCONFIG_REG[9:8]` CLOCKACTIVITY bit field is used to determine which clock will be shut down (`MCBSPi_FCLK`, `MCBSPi_ICLK`, none of them or both of them).

CLOCKACTIVITY setting is used in the McBSP module to determine on which part of the module the conditions to acknowledge the PRCM idle request will be tested. As an example, if `MCBSPi_FCLK` is said not to be shut down upon a PRCM idle request, this means McBSP module will only consider `MCBSPi_ICLK` and the associated pending activities before acknowledging the request.

NOTE: Some of McBSP features are associated to `MCBSPi_ICLK` and others to `MCBSPi_FCLK`. Using the CLOCKACTIVITY along with the Smart Idle mode ensures that the features associated with the clock that will remain active are always enabled, even if McBSP has acknowledged an idle request. For more information, see [Section 21.3.2.4.4](#).

Table 21-5 lists the value of the bit field and indicates if the interface (`MCBSPi_ICLK`) and PRCM functional (`MCBSPi_FCLK`) clocks can be switched-off or not when an idle request is received by McBSP module.

Table 21-5. State of Clocks When the Module is in Idle State

CLOCKACTIVITY Value	Interface Clock (<code>MCBSPi_ICLK</code>)	PRCM Functional Clock (<code>CORE_96M_FCLK</code> or <code>PER_96M_FCLK</code>)
0b00	OFF	OFF
0b01	OFF	ON

Table 21-5. State of Clocks When the Module is in Idle State (continued)

CLOCKACTIVITY Value	Interface Clock (McBSPi_ICLK)	PRCM Functional Clock (CORE_96M_FCLK or PER_96M_FCLK)
0b10	ON	OFF
0b11	ON	ON

NOTE: OFF means this clock can be switched-off.

ON means this clock must be maintained during wake up period.

CAUTION

The PRCM module does not have any hardware mean to read CLOCKACTIVITY settings. It is thus software responsibility to ensure a consistent programming between McBSPi.MCBSPLP_SYSConfig_REG[9:8] CLOCKACTIVITY bit field and PRCM 96M_FCLK and L4_ICLK control bits (for more information about clocks, see [Section 21.3.2.2, Clocks](#)). If McBSP module is disabled in both CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its idle request which will be acknowledged regardless of the features associated with the McBSP clocks. This may lead to unpredictable behaviors.

The software can disable all clocks at the McBSP module level by setting the IDLE_EN bit in McBSPi.MCBSPLP_PCR_REG[14] registers. The IDLE_EN bit allows stopping all the clocks in the McBSP module (legacy):

- When set to 0, the McBSP module is running.
- When set to 1, the clocks in the McBSP module are shut off when both IDLE_EN =1 and his power domain is in idle mode.

21.3.2.4.3 Wake-Up Capability

When configured in smart-Idle mode, the sources for wake-up generation are a subset of the interrupt sources. The wake up sources are enabled by setting the McBSPi.MCBSPLP_SYSConfig_REG[2] ENAWAKEUP bit (wake up feature control):

- Set to 0, wake up capability is disabled.
- Set to 1, wake up capability is enabled.

The McBSPi_SWAKEUP signal is the McBSP module asynchronous wake-up signal sent to the PRCM module when a wake-up generation is requested.

The wake up configurations are defined by setting the corresponding bits in the McBSPi.MCBSPLP_WAKEUPEN_REG register.

21.3.2.4.3.1 Receive Wakeup

There are four receive possible wake-up configurations:

- McBSPi.MCBSPLP_WAKEUPEN_REG[3] RRDYEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when the receive buffer reaches the high threshold value (RTHRESHOLD value + 1) of the McBSPi.MCBSPLP_THRS1_REG register. If the McBSPi.MCBSPLP_IRQENABLE_REG[3] RRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit changes from '0' to '1', indicating that received data is ready to be read).

- McBSPi.[MCBSPLP_WAKEUPEN_REG](#)[2] REOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request at the end of the frame. If the McBSPi.[MCBSPLP_IRQENABLE_REG](#)[2] REOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting idle mode.
- McBSPi.[MCBSPLP_WAKEUPEN_REG](#)[1] RFSREN bit: The McBSP module sends a McBSPi_SWAKEUP request to the PRCM module when a receive frame-sync pulse is detected while the McBSP module is in idle mode. If the McBSPi.[MCBSPLP_IRQENABLE_REG](#)[1] RFSREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting idle mode.
- McBSPi.[MCBSPLP_WAKEUPEN_REG](#)[0] RSYNCERREN bit: The McBSP module asserts the McBSPi_SWAKEUP request when an unexpected receive frame-sync pulse is detected. If the McBSPi.[MCBSPLP_IRQENABLE_REG](#)[0] RSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[0] RSYNCERR bit changes from '0' to '1', indicating that a receive error occurred).

21.3.2.4.3.2 Transmit Wakeup

For transmit, there are also five possible wake-up configuration scenarios:

- McBSPi.[MCBSPLP_WAKEUPEN_REG](#)[14] XEMPTYEOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when a complete frame was transmitted and the transmit buffer is empty. If the McBSPi.[MCBSPLP_IRQENABLE_REG](#)[14] XEMPTYEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.[MCBSPLP_WAKEUPEN_REG](#)[10] XRDYEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when the transmit buffer reaches the high threshold value (XTHRESHOLD value + 1) of the McBSPi.[MCBSPLP_THRSH2_REG](#) register. If the McBSPi.[MCBSPLP_IRQENABLE_REG](#)[10] XRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[10] XRDY bit changes from 0 to 1, indicating that transmit buffer data is ready to accept new data).
- McBSPi.[MCBSPLP_WAKEUPEN_REG](#)[9] XEOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request at the end of the frame. If the McBSPi.[MCBSPLP_IRQENABLE_REG](#)[9] XEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.[MCBSPLP_WAKEUPEN_REG](#)[8] XFSXEN bit: The McBSP module sends a McBSPi_SWAKEUP request when a transmit frame-sync pulse is detected while the module is in idle mode. If the McBSPi.[MCBSPLP_IRQENABLE_REG](#)[8] XFSXEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.[MCBSPLP_WAKEUPEN_REG](#)[7] XSYNCERREN bit: The McBSP module asserts the McBSPi_SWAKEUP request when an unexpected transmits frame-sync pulse is detected. If the McBSPi.[MCBSPLP_IRQENABLE_REG](#)[7] XSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[7] XSYNCERR bit changes from '0' to '1', indicating that a transmit error occurred).

21.3.2.4.3.3 Notes

When mcbsp1_fsr/mcbspi_fsx pins is configured as an output, the FSR/FSX wake-up generation makes no sense (the module cannot be in smart-idle mode).

Detection of RSYNCERR/XSYNCERR during idle mode can be used only when mcbsp1_fsr/mcbspi_fsx pins is configured as an input and the remote system knows to assert such an error to trigger the wake up of the McBSP module.

The module does not implement interrupt request (IRQ) assertion when configured as (GPIO). Pins that can be used to accept input signals and/or send output signals but are not linked to specific uses); also a wake up capability in this mode is not available.

21.3.2.4.4 Analysis of the Receiver Smart-Idle Behavior

The analysis of the power mode behavior is shown in [Table 21-6](#) :

In this table, the CLKRM bit is in the McBSPi.[MCBSPLP_PCR_REG](#) register on position 8, CLKXM bit in the McBSPi.[MCBSPLP_PCR_REG\[9\]](#) register, and CLOCKACTIVITY bit in the McBSPi.[MCBSPLP_SYSCONFIG_REG\[9:8\]](#) register.

The value X signifies that the bit value is not significant.

Table 21-6. McBSP Smart Idle Mode Configuration Behavior

CLKRM Bit	CLKXM Bit	McBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
0	0	Slave	outside	0bXX	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit buffer threshold synchronization (only when wake-up event is set on transmit threshold reached), regardless of the CLOCKACTIVITY settings or receive and transmit activity.
0	1	Transmit Master	McBSPi_ICLK	0b0X	The McBSP will not acknowledge the idle request unless: <ul style="list-style-type: none"> The transmit part is disabled (XDISABLE) or under software reset (XRST) and the receive part is not using the transmit loop-back clock (CLKR is not connected to the CLKX input pin). Both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) The idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable.
			CLKS	0bX0	
			McBSPi_ICLK	0b1X	
			CLKS	0bX1	
			CLKR (outside)	0bXX	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.

Table 21-6. McBSP Smart Idle Mode Configuration Behavior (continued)

CLKRM Bit	CLKXM Bit	McBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
1	0	Receive master	McBSPi_ICLK	0b0X	The McBSP will not acknowledge the idle request unless: The receive part is disabled (RDISABLE) or under software reset (RRST) The Idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames where completed in case of transmit and/or receive disable.
			CLKS	0bX0	
			McBSPi_ICLK	0b1X	
			CLKS	0bX1	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKX	0bXX	When CLKX is used as source (functional clock is provided from outside) then the module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.
1	1	Transmit and Receive Master	McBSPi_ICLK	0b0X	The McBSP will not acknowledge the idle request unless: Both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) The idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable. Note that no wake-up event is available in this mode since the entire McBSP and remote device activity is frozen.
			CLKS	0bX0	
			McBSPi_ICLK	0b1X	
			CLKS	0bX1	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).

NOTE: The RFSREN/XFSXEN mode is suitable for wake-up generation when both clocks (PRCM functional and interface) are switched off and mcbsp1_fsr/mcbspi_fsx pins is configured as input. The frame-sync pulse is asynchronously detected during idle.

The RSYNCERREN/XSYNCERREN mode can be used to wake-up the McBSP module only by a remote module implementing such a feature, to trigger a wake up. This mode requires functional clock to be active.

21.3.3 Hardware Requests

21.3.3.1 DMA Requests

The DMA requests are shared between the IVA2.2 subsystem DMA controller (eDMA) and system DMA controller (sDMA). Each of the five McBSP modules can generate two DMA events:

- McBSPi_DMA_TX : McBSPi module transmit request
- McBSPi_DMA_RX : McBSPi module receive request

The following table summarizes the DMA events with the mapping on both DMA controllers.

Table 21-7. McBSP DMA Requests

Request Name	Mapping	Destination	Description
McBSP1_DMA_TX	EDMA_REQ[0] S_DMA_30	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP1_DMA_RX	EDMA_REQ[1] S_DMA_31	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP2_DMA_TX	EDMA_REQ[2] S_DMA_32	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP2_DMA_RX	EDMA_REQ[3] S_DMA_33	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP3_DMA_TX	EDMA_REQ[4] S_DMA_16	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP3_DMA_RX	EDMA_REQ[5] S_DMA_17	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP4_DMA_TX	EDMA_REQ[6] S_DMA_18	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP4_DMA_RX	EDMA_REQ[7] S_DMA_19	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP5_DMA_TX	EDMA_REQ[8] S_DMA_20	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP5_DMA_RX	EDMA_REQ[9] S_DMA_21	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request

21.3.3.2 Interrupt Requests

21.3.3.2.1 McBSP Interrupt Requests

Each of the five McBSP modules can generate three interrupts, shared between the MPU subsystem and IVA2.2 subsystem interrupt controllers:

- McBSPi_IRQ: McBSPi module common interrupt request
- McBSPi_IRQ_TX: McBSPi module transmit interrupt request
- McBSPi_IRQ_RX: McBSPi module receive interrupt request

The following tables list the interrupt requests with the mapping.

Table 21-8. McBSP Common Interrupt Requests

Request Name	Mapping	Destination
McBSP1_IRQ	IVA2_IRQ[33] M_IRQ_16	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP2_IRQ	IVA2_IRQ[34] M_IRQ_17	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP3_IRQ	IVA2_IRQ[35] M_IRQ_22	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP4_IRQ	IVA2_IRQ[36] M_IRQ_23	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

Table 21-8. McBSP Common Interrupt Requests (continued)

Request Name	Mapping	Destination
McBSP5_IRQ	IVA2_IRQ[37] M_IRQ_27	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

Table 21-9. McBSP Transmit Interrupt Requests

Request Name	Mapping	Destination
McBSP1_IRQ_TX	IVA2_IRQ[16] M_IRQ_59	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP2_IRQ_TX	IVA2_IRQ[19] M_IRQ_62	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP3_IRQ_TX	IVA2_IRQ[21] M_IRQ_89	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP4_IRQ_TX	IVA2_IRQ[23] M_IRQ_54	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP5_IRQ_TX	IVA2_IRQ[25] M_IRQ_81	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

Table 21-10. McBSP Receive Interrupt Requests

Request Name	Mapping	Destination
McBSP1_IRQ_RX	IVA2_IRQ[17] M_IRQ_60	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP2_IRQ_RX	IVA2_IRQ[20] M_IRQ_63	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP3_IRQ_RX	IVA2_IRQ[22] M_IRQ_90	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP4_IRQ_RX	IVA2_IRQ[24] M_IRQ_55	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP5_IRQ_RX	IVA2_IRQ[26] M_IRQ_82	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

An event can generate an interrupt request when the corresponding mask bit in the McBSPi.[MCBSPLP_IRQENABLE_REG](#) register is set to '1'.

[Table 21-11](#) and [Table 21-12](#) summarize the events causing the generation of an interrupt request.

Table 21-11. McBSP Transmit Interrupt Events

Event Name	Status Bit	Mask Bit	Description
Transmit buffer empty at end of frame	McBSPi. MCBSPLP_IRQSTATUS_REG [14] XEMPTYEOF	McBSPi. MCBSPLP_IRQENABLE_REG [14] XEMPTYEOFEN	This event happens when a complete frame was transmitted and the transmit buffer is empty .
Overflow	McBSPi. MCBSPLP_IRQSTATUS_REG [12] XOVFLSTAT	McBSPi. MCBSPLP_IRQENABLE_REG [12] XOVFLEN	This event happens when transmit data buffer is full and a new data is written in this buffer. The new data written is discarded.
Underflow	McBSPi. MCBSPLP_IRQSTATUS_REG [11] XUNDLSTAT	McBSPi. MCBSPLP_IRQENABLE_REG [11] XUNDflen	This event happens when transmit data buffer is empty and a new data is required to be transmitted.
Threshold reached	McBSPi. MCBSPLP_IRQSTATUS_REG [10] XRDY	McBSPi. MCBSPLP_IRQENABLE_REG [10] XRDYEN	This event happens when the transmit buffer free locations are equal or above the THRSH2_REG value.
End of Frame	McBSPi. MCBSPLP_IRQSTATUS_REG [9] XEOF	McBSPi. MCBSPLP_IRQENABLE_REG [9] XEOFLEN	This event happens when a complete frame was transmitted.

Table 21-11. McBSP Transmit Interrupt Events (continued)

Event Name	Status Bit	Mask Bit	Description
Frame-sync	McBSPi.MCBSPPLP_IRQSTATUS_REG[8] XFSX	McBSPi.MCBSPPLP_IRQENABLE_REG [8] XFSXEN	This event happens when a new transmit frame synchronization is asserted.
Frame-sync error	McBSPi.MCBSPPLP_IRQSTATUS_REG[7] XSYNCERR	McBSPi.MCBSPPLP_IRQENABLE_REG [7] XSYNCERREN	This event happens when a transmit frame synchronization error is detected.

Table 21-12. McBSP Receive Interrupt Events

Event Name	Status bit	Mask bit	Description
Overflow	McBSPi.MCBSPPLP_IRQS TATUS_REG[5] ROVFLSTAT	McBSPi.MCBSPPLP_IRQENABLE_ REG[5] ROVFLLEN	This event happens when receive data buffer is full and a new data is written in this buffer. The new data written is discarded.
Underflow	McBSPi.MCBSPPLP_IRQS TATUS_REG[4] XUNDLSTAT	McBSPi.MCBSPPLP_IRQENABLE_ REG[4] RUNDflen	This event happens when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined.
Threshold reached	McBSPi.MCBSPPLP_RQS TATUS_REG[3] RRDY	McBSPi.MCBSPPLP_IRQENABLE_ REG[3] RRDYEN	This event happens when the receive buffer occupied locations are equal or above the THRSH1_REG value.
End of Frame	McBSPi.MCBSPPLP_IRQS TATUS_REG[2] REOF	McBSPi.MCBSPPLP_IRQENABLE_ REG[2] REOFLLEN	This event happens when a complete frame was received.
Frame-sync	McBSPi.MCBSPPLP_IRQS TATUS_REG[1] RFSR	McBSPi.MCBSPPLP_IRQENABLE_ REG[1] RFSREN	This event happens when a new receive frame synchronization is asserted.
Frame-sync error	McBSPi.MCBSPPLP_IRQS TATUS_REG[0] RSYNCERR	McBSPi.MCBSPPLP_IRQENABLE_ REG[0] RSYNCERREN	This event happens when a receive frame synchronization error is detected.

Once an interrupt request is generated, the software must read the McBSPi.MCBSPPLP_IRQSTATUS_REG register to check what event has caused the interrupt request generation, and acknowledge each processed event by writing a 1 to the corresponding bit in the McBSPi.MCBSPPLP_IRQSTATUS_REG register.

NOTE: All Status bits can be cleared in two ways:

- If the corresponding mask bit is set to '1' (interrupt generation enabled), the status bit is cleared by writing a '1'.
- If the corresponding mask bit is cleared to '0' (interrupt generation disabled), the status bit is cleared when a new start or stop condition is detected on the receiver/transmitter.

21.3.3.2.2 SIDETONE_McBSP Interrupt Requests

The McBSP2 and McBSP3 can generate another interrupt to the MPU subsystem interrupt controller:

- **ST_McBSPi_IRQ:** SIDETONE interrupt request for McBSPi module (where I = 2, 3).

Table 21-13. SIDETONE_McBSP Interrupt Requests

Request Name	Mapping	Destination
ST_McBSP2_IRQ	M_IRQ_4	MPU subsystem interrupt controller
ST_McBSP3_IRQ	M_IRQ_5	MPU subsystem interrupt controller

Table 21-14. SIDETONE_McBSP Interrupt Events

Event Name	Status Bit	Mask Bit	Description
Over-run	McBSPi. ST_IRQSTATUS_REG[0] OVRRERROR	McBSPi. ST_IRQENABLE_REG[0] OVRERRROREN	This event happens when a new data to be processed arrives before the previous one has ended.

Once an interrupt request has been generated, the software must read the McBSPi.[ST_IRQSTATUS_REG](#) register to check what event caused the interrupt request generation, and acknowledge each processed event by writing a 1 to the corresponding bit in the McBSPi.[ST_IRQSTATUS_REG](#) register.

NOTE: The McBSPi.[ST_IRQSTATUS_REG\[0\]](#) OVRRERROR status bit can be cleared in two ways:

- If the McBSPi.[ST_IRQENABLE_REG\[0\]](#) OVRERRROREN mask bit is set to '1' (interrupt generation enabled), the status bit is cleared by writing a '1'.
- If the McBSPi.[ST_IRQENABLE_REG\[0\]](#) OVRERRROREN mask bit is cleared to '0' (interrupt generation disabled), the status bit is cleared when a new start or stop condition is detected on the SIDETONE channels.

21.4 McBSP Functional Description

This section is a functional description of the McBSP module.

21.4.1 Block Diagram

[Figure 21-21](#), [Figure 21-22](#), and [Figure 21-23](#) show functional block diagrams of the five instances of the McBSP modules.

These figures regroup the McBSP modules by categories:

- McBSP module without audio buffer and SIDETONE core: McBSP1, McBSP4 and McBSP5
- McBSP module with audio buffer and SIDETONE core: McBSP2
- McBSP module without audio buffer, but with SIDETONE core: McBSP3

Figure 21-21. McBSP1, McBSP4 and McBSP5 Block Diagrams

Figure 21-22. McBSP2 Block Diagram

mcbsp-022

Figure 21-23. McBSP3 Block Diagram

mcbsp-023

21.4.2 McBSP Data Transfer Process

For McBSP1, McBSP3, McBSP4, and McBSP5 modules, receive and transmit operations are triple-buffered (512 bytes buffers organized in 32-bit words are used).

For the McBSP2 module, receive and transmit operations are quadruple-buffered (5K bytes buffers organized in 32-bit words are used). Receive and transmit buffers are separated in two memories: The same buffer as the others McBSP modules (1K bytes) and an audio buffer (4K bytes). The audio buffer is the largest one and is clocked by the interface clock, while the other buffer is used for synchronizing data to/from the audio buffer with the functional transmit/receive clock domains. [Figure 21-25](#) shows this implementation in the McBSP2 data transfer paths.

All registers of McBSP data transfer paths are 32-bits wide. [Figure 21-24](#) and [Figure 21-25](#) illustrate the McBSP data transfer paths.

CAUTION

The McBSP registers (DRR_REG and DXR_REG) are limited to 32-bit data accesses (L4 Interconnect). 16-bit and 8-bit is not allowed and can corrupt register content.

Figure 21-24. McBSP Data Transfer Paths

mcbsp-024

Figure 21-25. McBSP2 Data Transfer Paths

mcbsp-068

21.4.2.1 Data Transfer Process for 8- / 12- / 16- / 20- / 24- / 32-bits Long Words

CAUTION

For each data word length, one data occupies one 32-bit buffer word.

Receive data arrives on the mcbspi_dr pin and is shifted into the receive shift register (RSR). When a full word (depending on the data length configuration) is received, the content of the shift register is copied into the receive buffer (RB) if it is not full. When the RB threshold is reached the McBSP module asserts DMA or interrupt request and the RB content is then transferred (the sDMA or the eDMA controller reads the data receive register McBSPi.[MCBSPLP_DRR_REG](#)).

Transmit data is written by the MPU subsystem, the IVA2.2 subsystem or the DMA controller to data transmit register (McBSPi.[MCBSPLP_DXR_REG](#)) using the McBSPi.[MCBSPLP_SPCR2_REG\[1\]](#) XRDY bit enable input (when a byte is not enabled, the byte value in the memory will contain the previous written value). If there is no previous data in transmit shift register (XSR), the value from the transmit buffer (XB) is copied to XSR; otherwise, the content is copied to the XSR when the last bit of the previous data is shifted out on the mcbspi_dx pin.

21.4.2.2 Bit Reordering (Option to Transfer LSB First)

Generally, the McBSP module transmits or receives all data with the MSB first. However, some data protocols require the LSB to be transferred first.

If you set McBSPi.[MCBSPLP_XCR2_REG\[4:3\]](#) XREVERSE = 0b01, the bit ordering of the data words is reversed (LSB first) before being sent to the serial port. If you set McBSPi.[MCBSPLP_RCR2_REG\[4:3\]](#) RREVERSE = 0b01, the bit ordering of the data words is reversed during reception (LSB first).

This feature is available for all the data formats from 8-to 32-bit data length.

21.4.2.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

Figure 21-26. Conceptual Block Diagram for Clock and Frame Generation When MCBSPLP_SPCR1_REG[15] ALB = 0 and CONTROL_DEVCONF0[3] MCBSP1_CLKR = 0

mcbsp-025

The CLKR_int clock signal can be derived from three sources:

- The sample rate generator (CLKG): When [MCBSPLP_XCCR_REG\[5\]](#) DLB = 1 or [MCBSPLP_SRGR2_REG\[15\]](#) GSYNC = 1
- mcbsp1_clk pin (CLKR): When [MCBSPLP_PCR_REG\[9\]](#) CLKXM = 0 and [MCBSPLP_XCCR_REG\[15\]](#) EXTCLKGATE = 0, and [MCBSPLP_XCCR_REG\[5\]](#) DLB = 0 or [MCBSPLP_SRGR2_REG\[15\]](#) GSYNC = 0
- mcbspi_clk pin (CLKX): When [MCBSPLP_PCR_REG\[9\]](#) CLKXM = 1 and [MCBSPLP_XCCR_REG\[15\]](#) EXTCLKGATE = 1, and [MCBSPLP_XCCR_REG\[5\]](#) DLB = 0 or [MCBSPLP_SRGR2_REG\[15\]](#) GSYNC = 0

The CLKX_int clock signal can be derived from two sources:

- The sample rate generator (CLKG): When [MCBSPLP_PCR_REG\[9\]](#) CLKXM = 1, [MCBSPLP_XCCR_REG\[5\]](#) DLB = 1, or [MCBSPLP_SRGR2_REG\[15\]](#) GSYNC = 1
- mcbspi_clk pin (CLKX): When [MCBSPLP_PCR_REG\[9\]](#) CLKXM = 0, [MCBSPLP_XCCR_REG\[5\]](#) DLB = 0, or [MCBSPLP_SRGR2_REG\[15\]](#) GSYNC = 0

The FSR_int frame-sync signal can be derived from three sources:

- The sample rate generator (FSG): When [MCBSPLP_XCCR_REG\[5\]](#) DLB = 1, [MCBSPLP_SRGR2_REG\[15\]](#) GSYNC = 1, or [MCBSPLP_PCR_REG\[10\]](#) FSRM = 1 and [MCBSPLP_PCR_REG\[8\]](#) CLKRM = 1

- mcbsp1_fsr pin (FSR): When [MCBSPLP_PCR_REG\[9\]](#) CLKXM = 0 and [MCBSPLP_XCCR_REG\[15\]](#) EXTCLKGATE = 0 and [MCBSPLP_XCCR_REG\[5\]](#) DLB = 0 or [MCBSPLP_SRGR2_REG\[15\]](#) GSNC = 0, or [MCBSPLP_PCR_REG\[10\]](#) FSRM = 0 and [MCBSPLP_PCR_REG\[8\]](#) CLKRM = 0
- mcbspi_fsx pin (FSX): When [MCBSPLP_PCR_REG\[9\]](#) CLKXM = 1 and [MCBSPLP_XCCR_REG\[15\]](#) EXTCLKGATE = 1, and [MCBSPLP_XCCR_REG\[5\]](#) DLB = 0 or [MCBSPLP_SRGR2_REG\[15\]](#) GSNC = 0, or [MCBSPLP_PCR_REG\[10\]](#) FSRM = 0 and [MCBSPLP_PCR_REG\[8\]](#) CLKRM = 0

The FSX_int frame-sync signal can be derived from two sources:

- The sample rate generator (FSG): When [MCBSPLP_XCCR_REG\[5\]](#) DLB = 1 or [MCBSPLP_SRGR2_REG\[15\]](#) GSNC = 1, or [MCBSPLP_SRGR2_REG\[12\]](#) FSGM = 1 and [MCBSPLP_PCR_REG\[11\]](#) FSXM = 1
- mcbspi_fsx pin (FSX): When [MCBSPLP_XCCR_REG\[5\]](#) DLB = 0 or [MCBSPLP_SRGR2_REG\[15\]](#) GSNC = 0, or [MCBSPLP_SRGR2_REG\[12\]](#) FSGM = 0 and [MCBSPLP_PCR_REG\[11\]](#) FSXM = 0

21.4.2.3.1 Clocking

Data is shifted one bit at a time from the mcbspi_dr pin to the RSRs or from the XSRs to the mcbspi_dx pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR_int) controls bit transfers from the mcbspi_dr pin to the RSRs. The transmit clock signal (CLKX_int) controls bit transfers from the XSRs to the mcbspi_dx pin. CLKR_int or CLKX_int signals can be derived from a pin at the boundary of the McBSP module (mcbspi_clk and mcbspi_clkx respectively) or derived from inside the McBSP module (see [Figure 21-26](#)). The clocks source is selected by programming the McBSPi.[MCBSPLP_PCR_REG\[9\]](#) CLKXM bit and the McBSPi.[MCBSPLP_PCR_REG\[8\]](#) CLKRM bit respectively.

When the McBSPi.[MCBSPLP_PCR_REG\[9\]](#) CLKXM bit (transmitter clock mode) is set to:

- 0: CLKX_int is driven by an external clock and mcbspi_clkx is an input pin.
- 1: CLKX_int is driven by the internal sample rate generator and mcbspi_clkx is an output pin.

For the McBSPi.[MCBSPLP_PCR_REG\[8\]](#) CLKRM bit (receiver clock mode), see [Table 21-15](#).

Table 21-15. Receiver Clock Mode

Value	Digital loop back mode	mcbspi_clk pin	Description
0x0	McBSPi. MCBSPLP_XCCR_REG[5] DLB bit =0	input	CLKR_int is driven by an external clock
	McBSPi. MCBSPLP_XCCR_REG[5] DLB bit =1	High-impedance	CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the CLKXM value.
0x1	McBSPi. MCBSPLP_XCCR_REG[5] DLB bit =0	output	CLKR_int is driven by the internal sample rate generator
	McBSPi. MCBSPLP_XCCR_REG[5] DLB bit =1	output	CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the CLKXM value.

The polarities of CLKR and CLKX signals are configured in McBSPi.[MCBSPLP_PCR_REG](#) register.

The McBSPi.[MCBSPLP_PCR_REG\[1\]](#) CLKXP defines the transmit clock polarity:

- When set to 0, transmit data driven on rising edge of CLKX signal
- When set to 1, transmit data driven on falling edge of CLKX signal

The McBSPi.[MCBSPLP_PCR_REG\[0\]](#) CLKRP defines the receive clock polarity:

- When set to 0, receive data sampled on falling edge of CLKX signal
- When set to 1, transmit data sampled on rising edge of CLKX signal

[Figure 21-27](#) gives an example where the clock signal controls the timing of each bit transfer on the pin.

Figure 21-27. Clock Signal Control of Bit Transfer Timing

mcbsp-026

NOTE: The McBSP module is constrained to operate at an internal functional frequency of up to L4 interface frequency divided by 2. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal sample rate generator for CLKX/CLKR/CLKS, choose an appropriate input clock frequency (up to L4 interface frequency) and divide down value by programming the [McBSPi.MCBSPLP_SRGR1_REG\[7:0\]](#) CLKGDV bit field.

21.4.2.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (`mcbspi_dr` or `mcbspi_dx`) are transferred in a group called a serial word. The software defines how many bits are in a word by programming:

- For the receiver: the [McBSPi.MCBSPLP_RCR1_REG\[7:5\]](#) RWDLEN1 bit field and the [McBSPi.MCBSPLP_RCR2_REG\[7:5\]](#) RWDLEN2 bit field.
- For the transmitter: the [McBSPi.MCBSPLP_XCR1_REG\[7:5\]](#) XWDLEN1 bit field and the [McBSPi.MCBSPLP_XCR2_REG\[7:5\]](#) XWDLEN2 bit field.

The difference of use is explained to [Section 21.4.2.4.1](#).

The various possibilities of word length are 8, 12, 16, 20, 24, and 32 bits (for field values, see [Section 21.6](#))

Bits coming from the `mcbspi_dr` pin are held in the RSR until it holds a full serial word, then the word is passed to the RB and to the [McBSPi.MCBSPLP_DRR_REG](#) register.

During transmission, XSR accepts new data from XB after a full serial word has been passed from XSR to the `mcbspi_dx` pin.

In the example in [Figure 21-27](#), an 8-bit word size was defined (see the transfer of the 8-bit word B).

21.4.2.3.3 Frames and Frame Synchronization

One or more words (up to 128) are transferred in a group called a frame. The software defines how many words are in a frame by programming:

- For the receiver: The [McBSPi.MCBSPLP_RCR1_REG\[14:8\]](#) RFRLLEN1 bit field and the [McBSPi.MCBSPLP_RCR2_REG\[14:8\]](#) RFRLLEN2 bit field.
- For the transmitter: The [McBSPi.MCBSPLP_XCR1_REG\[14:8\]](#) XFRLEN1 bit field and the [McBSPi.MCBSPLP_XCR2_REG\[14:8\]](#) XFRLEN2 bit field.

The difference between these registers is explained to [Section 21.4.2.4.1](#). For the corresponding between field value and words number, see [Section 21.6](#).

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-synchronization signals (FSG) to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on.

Pulses on the receive frame-synchronization (FSR_int) signal initiate frame transfers on mcbspi_dr. Pulses on the transmit frame-sync (FSX_int) signal initiate frame transfers on mcbspi_dx. FSR_int or FSX_int signals can be derived from a pin at the boundary of the McBSP module (mcbspi_fsr and mcbspi_fsx respectively) or derived from inside the McBSP module (see [Figure 21-25](#)). The frame-sync source is selected by programming the McBSPi.[MCBSPLP_PCR_REG\[11\]](#) FSXM bit and the McBSPi.[MCBSPLP_PCR_REG\[10\]](#) FSRM bit respectively.

When the McBSPi.[MCBSPLP_PCR_REG\[11\]](#) FSXM bit (transmitter frame-sync mode) is set to:

- 0: FSX_int is derived from an external source and mcbspi_fsx is an input pin.
- 1: FSX_int is determined by the McBSPi.[MCBSPLP_SRGR2_REG\[12\]](#) FSGM bit and mcbspi_fsx is an output pin.

For the McBSPi.[MCBSPLP_PCR_REG\[10\]](#) FSRM bit (receiver frame-sync mode), is set to:

- 0: FSR_int is generated by an external source and mcbsp1_fsr is an input pin.
- 1: FSR_int is generated internally by sample rate generator. The mcbsp1_fsr is an output pin except when McBSPi.[MCBSPLP_SRGR2_REG\[15\]](#) GSYNC bit = 0x1.

In the example in [Figure 21-26](#), a one-word frame is transferred when a frame-synchronization pulse occurs. The polarities of FSR and FSX signals are programmable by bits on McBSPi.[MCBSPLP_PCR_REG](#) register.

The McBSPi.[MCBSPLP_PCR_REG\[3\]](#) FSXP bit defines the transmit frame-sync polarity:

- When set to 0,, frame-sync pulse FSX is active high.
- When set to 1, frame-sync pulse FSX is active low.

The McBSPi.[MCBSPLP_PCR_REG\[2\]](#) FSRP bit defines the receive frame-sync polarity:

- When set to 0, frame-sync pulse FSR is active high.
- When set to 1, frame-sync pulse FSR is active low.

In McBSP operation, the inactive-to-active transition of the frame-synchronization signal indicates the start of the next frame. For this reason, the frame-synchronization signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

21.4.2.3.4 Detecting Frame-Synchronization Pulses, Even in Reset State

The McBSP module can generate receive and transmit interrupts to the MPU/IVA2.2 subsystems to indicate specific events in the McBSP module. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-synchronization pulses (see [Section 21.5](#) for further details).

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating receive interrupt when the receiver is in reset). In this case, McBSPi.[MCBSPLP_PCR_REG\[0\]](#) FSRM bit/McBSPi.[MCBSPLP_PCR_REG\[1\]](#) FSXM bit and McBSPi.[MCBSPLP_PCR_REG\[2\]](#) FSRP bit/McBSPi.[MCBSPLP_PCR_REG\[3\]](#) FSXP bit still select the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in the reset state, these signals are synchronized to the interface clock (McBSPi_ICLK) and then sent to the MPU/IVA2.2 subsystem in the form of receive interrupt and transmit interrupt at the point where they feed the receiver and transmitter of the serial port. Consequently, a new frame-synchronization pulse can be detected, and then, the MPU/IVA2.2 subsystem can take the serial port out of reset safely.

21.4.2.3.5 Ignoring Frame-Synchronization Pulses

The McBSP module ignores transmit and/or receive frame-synchronization pulses if the frame transfer was started by a previous frame-synchronization pulse (unexpected frame-synchronization pulses). The McBSP module does not support features like retransmit or re-receive of an erroneous frame or word. The receiver or transmitter ignores frame-synchronization pulses until the desired frame length or number of words is reached. For more details on unexpected frame-synchronization pulses, see [Section 21.4.4.3](#), or [Section 21.4.4.6](#).

21.4.2.3.6 Frame Frequency

The frame frequency is determined by the period between frame-synchronization pulses and is defined as shown in the following equation:

Frame frequency = Clock frequency/(Number of clock cycles between two rising edges [or falling edges] of two consecutive frame synchronization pulses)

The frame frequency can be increased by decreasing the time between frame-synchronization pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

21.4.2.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame synchronization pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined as shown in the following equation:

Maximum frame frequency = clock frequency/Number of bits per frame

[Figure 21-28](#) below shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

Figure 21-28. McBSP Operating at Maximum Packet Frequency

If there is a 1-bit data delay as shown in [Figure 21-28](#), the frame-synchronization pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, back-to-back transfers.

NOTE: For McBSPi.MCBSPPLP_XCR2_REG[1:0] XDATDLY = 0x0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX_int). For more details, see [Section 21.5.1.6.2.2.5](#).

21.4.2.4 Frame Phases (Dual-Phase Frame I2S Support)

The McBSP module allows you to configure each frame to contain one or two phases. The support for dual-phase frames is required to provide I2S fully compliant capabilities (audio left and right channels—stereo audio stream).

CAUTION

The limitation on dual-phase frame support is that the number of words per phase must be set to 1 for both first and second phase. It is the only possible value for word per frame when using the dual phase frame.

The number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, a user might define a frame as consisting of one phase containing one word of 16 bits, followed by a second phase consisting of one word of 32 bits. This configuration allows the user to compose frames for custom applications such as I2S protocol.

21.4.2.4.1 Number of Phases, Words, and Bits per Frame

Table 21-16 below shows which bit fields in the receive control registers (McBSPi.[MCBSPLP_RCR1_REG](#) and McBSPi.[MCBSPLP_RCR2_REG](#)) and in the transmit control registers (McBSPi.[MCBSPLP_XCR1_REG](#) and McBSPi.[MCBSPLP_XCR2_REG](#)) determine the number of phases per frame, the number of words per frame, and the number of bits per word for each phase, for both receiver and transmitter. The maximum number of words per frame is limited to 2 when using dual-phase frames (one word for each phase), and to 128 for a single-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

The following legend applies to the table:

- RPHASE = McBSPi.[MCBSPLP_RCR2_REG](#)[15] RPHASE bit
- XPHASE = McBSPi.[MCBSPLP_XCR2_REG](#)[15] XPHASE bit
- RFRLLEN1 = McBSPi.[MCBSPLP_RCR1_REG](#)[14:8] RFRLLEN1 field
- RFRLLEN2 = McBSPi.[MCBSPLP_RCR2_REG](#)[14:8] RFRLLEN2 field
- XFRLEN1 = McBSPi.[MCBSPLP_XCR1_REG](#)[14:8] XFRLEN1 field
- XFRLEN2 = McBSPi.[MCBSPLP_XCR2_REG](#)[14:8] XFRLEN2 field
- RWDLEN1 = McBSPi.[MCBSPLP_RCR1_REG](#)[7:5] RWDLEN1 field
- RWDLEN2 = McBSPi.[MCBSPLP_RCR2_REG](#)[7:5] RWDLEN2 field
- XWDLEN1 = McBSPi.[MCBSPLP_XCR1_REG](#)[7:5] XWDLEN1 field
- XWDLEN2 = McBSPi.[MCBSPLP_XCR2_REG](#)[7:5] XWDLEN2 field

Table 21-16. Phases, Words and Bits per Frame Control Bit

Operation	Number of phases	Words per frame set with	Bits per word set with
Reception	1 (RPHASE=0)	RFRLLEN1	RWDLEN1
Reception	2 (RPHASE=1)	RFRLLEN1=0x0 and RFRLLEN2=0x0	RWDLEN1 for phase 1 RWDLEN2 for phase 2
Transmission	1 (XPHASE=0)	XFRLEN1	XWDLEN1
Transmission	2 (XPHASE=1)	XFRLEN1=0x0 and XFRLEN2=0x0	XWDLEN1 for phase 1 XWDLEN2 for phase 2

21.4.2.4.2 Single-Phase Frame Example

Figure 21-29 below shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the `mcbspi_dx` and `mcbspi_dr` pins are available one clock cycle after FS(R/X) goes active. The following table shows the assumptions used in the example of this figure.

Table 21-17. Assumptions for the Single-Phase Frame Example

Assumption	Value	Bit or Field Name
Single-phase frame	'0'	McBSPi. MCBSPLP_RCR2_REG [15] RPHASE bit McBSPi. MCBSPLP_XCR2_REG [15] XPHASE bit
One word per frame	0x0	McBSPi. MCBSPLP_RCR1_REG [14:8] RFRLLEN1 field McBSPi. MCBSPLP_XCR1_REG [14:8] XFRLEN1 field
8-bit word length	0x0	McBSPi. MCBSPLP_RCR1_REG [7:5] RWDLEN1 field McBSPi. MCBSPLP_XCR1_REG [7:5] XWDLEN1 field
word length in register2	ignored	McBSPi. MCBSPLP_RCR2_REG [14:8] RFRLLEN2 field McBSPi. MCBSPLP_XCR2_REG [14:8] XWDLEN2 field
Receive data clocked on falling edge	'0'	McBSPi. MCBSPLP_PCR_REG [0] CLKRP bit
Transmit data clocked on rising edge	'0'	McBSPi. MCBSPLP_PCR_REG [1] CLKXP bit
Active-high frame-sync signals	'0'	McBSPi. MCBSPLP_PCR_REG [2] FSRP bit McBSPi. MCBSPLP_PCR_REG [3] FSXP bit
1-bit data delay	01b	McBSPi. MCBSPLP_RCR2_REG [1:0] RDATDLY field McBSPi. MCBSPLP_XCR2_REG [1:0] XDARDLY field

Figure 21-29. Single-Phase Frame for a McBSP Data Transfer**21.4.2.4.3 Dual-Phase Frame Example**

Figure 21-30 below shows an example of a frame. The first phase consists of one word of 16 bits, followed by a second phase of one word of 8 bits. The entire bit stream in the frame is contiguous. There are no gaps between words/phases. Table 21-18 shows the assumptions used to the example in Figure 21-30.

Table 21-18. Assumptions for the Dual-Phase Frame Example

Assumption	Value	Bit or Field name
Single-phase frame	'1'	McBSPi.MCBSPPLP_RCR2_REG[15] RPHASE bit
		McBSPi.MCBSPPLP_XCR2_REG[15] XPHASE bit
One word per frame	0x0	McBSPi.MCBSPPLP_RCR1_REG[14:8] RFRLEN1 field
		McBSPi.MCBSPPLP_XCR1_REG[14:8] XFRLEN1 field
16-bit word length	0x0	McBSPi.MCBSPPLP_RCR1_REG[7:5] RWDLEN1 field
		McBSPi.MCBSPPLP_XCR1_REG[7:5] XWDLEN1 field
8-bit word length	0x2	McBSPi.MCBSPPLP_RCR2_REG[14:8] RFRLEN2 field
		McBSPi.MCBSPPLP_XCR2_REG[14:8] XWDLEN2 field
Receive data clocked on falling edge	'0'	McBSPi.MCBSPPLP_PCR_REG[0] CLKRP bit
		McBSPi.MCBSPPLP_PCR_REG[1] CLKXP bit
Transmit data clocked on rising edge	'0'	McBSPi.MCBSPPLP_PCR_REG[2] FSRP bit
		McBSPi.MCBSPPLP_PCR_REG[3] FSXP bit
0-bit data delay	00b	McBSPi.MCBSPPLP_RCR2_REG[1:0] RDATDLY field
		McBSPi.MCBSPPLP_XCR2_REG[1:0] XDARDLY field

Figure 21-30. Dual-Phase Frame for a McBSP Data Transfer**21.4.2.5 McBSP Reception**

This section explains the fundamental process of reception in the McBSP module. For details about how to program the McBSP receiver, see [Section 21.5](#), [Section 21.5.1.4](#), and [Section 21.5.1.5](#).

Figure 21-31 and Figure 21-32 below show how reception occurs in the McBSP module. A description of the process follows the figures. Figure 21-31 shows the physical path for the data.

Figure 21-31. McBSP Reception Physical Data Path

Figure 21-32 is a timing diagram showing signal activity for one possible reception scenario.

Figure 21-32. McBSP Reception Signal Activity

RRDY: Status of receiver ready bit (high is 1)

mcbsp-031

The following process describes how data travels from the `mcbspi_dr` pin to the MPU/IVA2.2 subsystem or to the sDMA controller:

1. The McBSP module waits for a receive frame-synchronization pulse on `FSR_int`.
2. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.[MCBSPLP_RCR2_REG\[1:0\]](#) RDATDLY bits. In the preceding timing diagram a 1-bit data delay is selected.
3. The McBSP module accepts data bits on the `mcbspi_dr` pin and shifts them into the RSR. For details on choosing a word length, see [Section 21.5.1.5.2.2.2](#).
4. When a full word is received, the McBSP module copies the contents of the RSR to the RB, provided that RB is not full.
5. When the programmed receive threshold is reached (McBSPi.[MCBSPLP_THRSH1_REG\[10:0\]](#) RTHRESHOLD bit field), the McBSP module asserts the receiver ready bit (McBSPi.[MCBSPLP_SPCR1_REG\[1\]](#) RRDY bit). This indicates that receive data is ready to be read by the MPU/IVA2.2 subsystem or the sDMA controller by accessing McBSPi.[MCBSPLP_DRR_REG](#) register.

The data copied from RB to McBSPi.[MCBSPLP_DRR_REG](#) is justified and bit filled according to the McBSPi.[MCBSPLP_SPCR1_REG\[14:13\]](#) RJUST bit field.

6. The MPU/IVA2.2 subsystem or the sDMA controller reads the data from the data receive register. When the RB is empty, McBSPi.[MCBSPLP_SPCR1_REG\[1\]](#) RRDY bit is cleared.

21.4.2.6 McBSP Transmission

This section explains the fundamental process of transmission in the McBSP module. For details about how to program the McBSP transmitter, see [Section 21.5](#), and [Section 21.5.1.6](#).

Figures below show how transmission occurs in the McBSP module. A description of the process follows the figures. [Figure 21-33](#) shows the physical path for the data.

Figure 21-33. McBSP Transmission Physical Data Path

mcbsp-032

Figure 21-34 is a timing diagram showing signal activity for one possible transmission scenario.

Figure 21-34. McBSP Transmission Signal Activity

XRDY: Status of transmitter ready bit (high is 1)

mcbspi-033

1. The MPU/IVA2.2 subsystem or the sDMA controller writes data to the data transmit register (McBSPi.MCBSPPLP_DXR_REG). When the XB is reached the transmitter ready bit (McBSPi.MCBSPPLP_SPCR2_REG[1] XRDY bit) is cleared to indicate that the transmitter is not ready for new data. For details on choosing a word length, see [Section 21.5.1.6.2.2.2](#).
2. When new data arrives in McBSPi.MCBSPPLP_DXR_REG register, the McBSP module copies the content of the data transmit register to the XB. In addition, the transmit ready bit (McBSPi.MCBSPPLP_SPCR2_REG[1] XRDY bit) is set as long as the buffer contains at least the transmit threshold number of free locations (McBSPi.MCBSPPLP_THRSH2_REG[10:0] XTHRESHOLD field). This indicates that the transmitter is ready to accept new data from the MPU/IVA2.2 subsystem or the sDMA controller.
3. The McBSP module waits for a transmit frame-synchronization pulse on FSX_int.
4. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPPLP_XCR2_REG[1:0] XDATDLY field.
In the preceding timing diagram, a 1-bit data delay is selected.
5. The McBSP module shifts data bits from the XSR to the mcbspi_dx pin.

21.4.2.7 Enable/Disable the Transmit and Receive Processes

The McBSP module has the option to stop-resume the transmit/receive process while the module is in functional mode (out of transmit/receive reset).

When the transmit/receive disable bit (McBSPi.MCBSPPLP_XCCR_REG[0] XDISABLE/McBSPi.MCBSPPLP_RCCR_REG[0] RDISABLE) is set, the McBSP module stops the transmit/receive operation at the next frame boundary (frame corruption avoided).

During the receive disable state, the frames that are sent (when FSR signal is asserted while receive disable) by the remote device are lost, and receive buffer overflow status bit (McBSPi.MCBSPPLP_IRQSTATUS_REG[5] ROVFLSTAT) is not set. Also, the frames received by the remote device while McBSPi.MCBSPPLP_XCCR_REG[0] XDISABLE bit is set (when FSX signal is asserted while transmit disable) are meaningless undefined data frames, and transmit buffer underflow status bit (McBSPi.MCBSPPLP_IRQSTATUS_REG[11] XUNDFLSTAT) is not set. The presence of the frame synchronization, while transmit/receive process is disabled, can be checked by reading the transmit/receive Frame-sync interrupt status: McBSPi.MCBSPPLP_IRQSTATUS_REG[8] XFSX / McBSPi.MCBSPPLP_IRQSTATUS_REG[1] RFSR bits.

As soon as the McBSPi.MCBSPPLP_XCCR_REG[0] XDISABLE/McBSPi.MCBSPPLP_RCCR_REG[0] RDISABLE bit is cleared, the transmit/receive process resumes at the next frame boundary.

NOTE: It is not recommended to use this mechanism together with the possibility to interrogate the transmit/receive buffer status register (McBSPi.MCBSPPLP_XBUFFSTAT_REG[7:0] XBUFFSTAT/McBSPi.MCBSPPLP_RBUFFSTAT_REG[7:0] RBUFFSTAT bit field indicating the occupied/available buffer locations), since this register is an interface clock (McBSPi_ICLK) synchronous register and does not reflect the exact number of occupied/free locations available on the functional clock domain.

21.4.2.8 McBSP Data Transfer Mode

NOTE: For all examples in this section, the configured CLKX edge is the rising edge (McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit=0x0) and the configured CLKR edge is the falling edge (McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit=0x0). These are the reset values.

In timing diagrams below, a 1-bit data delay is selected (McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field=0x01 and McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY field=0x01), because data often follows a 1-cycle active frame-synchronisation.

McBSP modules can support 2 edge selection modes for transmit and receive data transfer at the system level:

- The full cycle mode, for which one clock period is used to transfer the data, generated on one edge and captured on the same edge (one clock period later).
- The half cycle mode, for which one half clock period is used to transfer the data, generated on one edge and captured on the opposite edge (one half clock period later). Note that a new data is generated only every clock period, which permits to guarantee the required hold time.

21.4.2.8.1 Transmit Full Cycle Mode

When configured in full cycle mode (McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE bit = 0x1), the FSX signal is sampled on the configured CLKX edge and the data is driven on the same configured edge. See [Figure 21-35](#).

Figure 21-35. Transmit Full Cycle Timing Diagram

21.4.2.8.2 Transmit Half Cycle Mode

When configured in half cycle mode (McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE bit = 0x0, reset value), the FSX signal is sampled on the opposite configured CLKX edge and the data is driven on the next configured edge. See [Figure 21-36](#).

Figure 21-36. Transmit Half Cycle Timing Diagram

21.4.2.8.3 Receive Full Cycle Mode

When configured in full cycle mode (McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bit = 0x1, reset value), the FSR signal is sampled on the configured CLKR edge and the data is driven on the same configured edge. See [Figure 21-37](#).

Figure 21-37. Receive Full Cycle Timing Diagram

mcbsp-071

21.4.2.8.4 Receive Half Cycle Mode

When configured in half cycle mode (McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bit = 0x0), the FSR signal is sampled on the opposite configured CLKR edge and the data is driven on the next configured edge. See [Figure 21-38](#).

Figure 21-38. Receive Half Cycle Timing Diagram

mcbsp-072

21.4.3 McBSP SRG

The McBSP module contains an internal SRG that can be used to generate an internal data clock (CLKG) and an internal frame-synchronization signal (FSG). CLKG can be used for bit shifting on the data receive pin (**mcbspi_dr**) and/or the data transmit pin (**mcbspi_dx**). FSG can be used to initiate frame transfers on **mcbspi_dr** pin and/or **mcbspi_dx** pin. [Figure 21-39](#) is a conceptual block diagram of the SRG.

Figure 21-39. Conceptual Block Diagram of the Sample Rate Generator

mcbsp-034

The source clock for the SRG (labeled CLKSRG in the diagram) can be supplied by either the interface clock (McBSPI_ICLK), or the functional clock (CLKS input), or by an external pin (mcbspi_clkx, or mcbspi_clkr). The source is selected with the McBSPI.[MCBSPLP_PCR_REG\[7\]](#) SCLKME bit and the McBSPI.[MCBSPLP_SRGR2_REG\[13\]](#) CLKSM bit.

If a pin or CLKS signal is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (McBSPI.[MCBSPLP_SRGR2_REG\[14\]](#) CLKSP bit, McBSPI.[MCBSPLP_PCR_REG\[1\]](#) CLKXP bit, or McBSPI.[MCBSPLP_PCR_REG\[0\]](#) CLKRP bit).

The SRG has a three-stage clock divider that gives CLKG and FSG programmability.

The three stages provide:

- Clock divide-down: The source clock (CLKSRG) is divided according to the McBSPI.[MCBSPLP_SRGR1_REG\[7:0\]](#) CLKGDV field to produce CLKG signal
- Frame period divide-down: CLKG is divided according to the McBSPI.[MCBSPLP_SRGR2_REG\[11:0\]](#) FPER field to control the period from the start of a frame-pulse to the start of the next pulse
- Frame-synchronization pulse-width countdown: CLKG cycles are counted according to the McBSPI.[MCBSPLP_SRGR1_REG\[15:8\]](#) FWID bit field to control the width of each frame-synchronization pulse

NOTE: The McBSP module cannot operate at an internal functional frequency faster than L4 interface frequency divided by 2. Choose an input clock frequency and a McBSPI.[MCBSPLP_SRGR1_REG\[7:0\]](#) CLKGDV value such that CLKG is less than or equal to L4 interface frequency divided by 2.

In addition to the three-stage clock divider, the sample rate generator has a frame-synchronization pulse detection and clock synchronization module that allows synchronization of the clock divide down with an incoming frame-synchronization pulse on the mcbspi_fsr pin. This feature is enabled or disabled with the McBSPI.[MCBSPLP_SRGR2_REG\[15\]](#) GSYNC bit.

CLKG is used as source to generate the output clocks CLKX/CLKR when the McBSPI.[MCBSPLP_PCR_REG\[9\]](#) CLKXM / McBSPI.[MCBSPLP_PCR_REG\[8\]](#) CLKRM bit indicates that the clock is an output. The output CLKX/CLKR is generated according to the clock polarity setting (see [Figure 21-26](#)).

For details on getting the sample rate generator ready for operation, see [Section 21.5](#).

21.4.3.1 Clock Generation in the SRG

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the SRG to drive clocking is controlled by the clock mode bits (McBSPi.MCBSPPLP_PCR_REG[9] CLKXM and McBSPi.MCBSPPLP_PCR_REG[8] CLKRM) and polarity mode bits (McBSPi.MCBSPPLP_PCR_REG[1] CLKXP and McBSPi.MCBSPPLP_PCR_REG[0] CLKRP).

When a clock mode bit is set to 1 (CLKRM=1 for reception, CLKXM=1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal SRG output clock (CLKG) according to the polarity setting.

The effects of this setting on the McBSP module are partially affected by the use of the digital loopback (DLB) mode, the analog loop back (ALB) mode and by the synchronous receive/transmit setting, respectively, as described in [Table 21-19](#). The ALB mode is selected with the McBSPi.MCBSPPLP_SPCR1_REG[15] ALB bit. The DLB mode is selected with the McBSPi.MCBSPPLP_XCCR_REG[5] DLB bit. The synchronous setting is controlled by input signals. These signals are defined by the control registers of the System Control Module (more details, refer [Section 21.3.1](#))

When using the SRG as a clock source, make sure the SRG is enabled (McBSPi.MCBSPPLP_SPCR2_REG[6] GRST bit =1).

Table 21-19. Effects of DLB and ALB Bits on Clock Modes

Mode Bit Settings		Effect
CLKRM=1	DLB=0 and ALB = 0 (Digital and analog loop back mode disabled)	mcbsp1_clk is an output pin driven by the SRG output clock (CLKG).
	DLB=0 and ALB = 1 (Digital loop back mode disabled and Analog loop back mode enabled)	<p>mcbsp1_clk is an output pin driven by the SRG output clock (CLKG).</p> <p>The receiver functional part internal clock is driven by CLKX input signal provided by mcbspi_clkx pin. The source of CLKX depends on the CLKXM bit.</p> <p>The receive frame synchronization is driven by FSX input signal provided by mcbspi_fsx pin.</p> <p>The receive data is driven by the DX input loop-back pin (mcbspi_dx).</p>
	DLB=1 ALB = 0 (Digital loop back mode enabled and Analog loop back mode disabled)	<p>The SRG and the frame synchronization generator must be enabled.</p> <p>The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity).</p> <p>The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity).</p> <p>The transmit data is connected to the DR input data.</p> <p>Note that in digital loop back mode no serial link activity will be seen by the remote device.</p>
	DLB=1 ALB = 1 (reserved mode)	Undefined functionality.

Table 21-19. Effects of DLB and ALB Bits on Clock Modes (continued)

Mode Bit Settings		Effect
CLKXM= 1	DLB=0 ALB = 0 (Digital analog loop back mode disabled)	mcbspi_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB=0 ALB = 1 (Digital loop back mode disabled and Analog loop back mode enabled)	mcbspi_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB=1 ALB = 0 (Digital loop back mode enabled and Analog loop back mode disabled)	The SRG and the frame synchronization generator need to be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. Note that in digital loop back mode no serial link activity will be seen by the remote device.
	DLB=1 ALB = 1 (reserved mode)	Undefined functionality.
	SCM.CONTROL_DEVCONF0[3] MCBSP1_CLKR bit =1 (synchronous setting and DLB = 0 ALB = 0)	CLKX is an output pin driven by the SRG output clock (CLKG). CLKR is connected to the CLKX.

21.4.3.2 Frame Sync Generation in the SRG

The SRG can produce a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both.

If you want the receiver to use FSG for frame synchronization, make sure McBSPi.[MCBSPLP_PCR_REG](#)[10] FSRM bit =1. (When FSRM=0, receive frame synchronization is supplied via the mcbspi_fsr pin.)

If you want the transmitter to use FSG for frame synchronization, you must set:

- McBSPi.[MCBSPLP_PCR_REG](#)[11] FSXM = 1: This indicates that transmit frame synchronization is supplied by the McBSP module itself rather than from the mcbspi_fx pin.
- [MCBSPLP_SRGR2_REG](#)[12] FSGM=1: This indicates that when FSXM=1, transmit frame synchronization is supplied by the SRG.

NOTE: When FSGM=0 and FSXM=1, the transmit frame-sync signal (FSX) is generated when XB is not empty. When FSGM = 0, McBSPi.[MCBSPLP_SRGR2_REG](#)[11:0] FPER and McBSPi.[MCBSPLP_SRGR1_REG](#)[15:8] FWID field are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition).

In either case, the SRG must be enabled (McBSPi.[MCBSPLP_SPCR2_REG](#)[6] GRST bit=1) and the frame-synchronization logic in the SRG must be enabled (McBSPi.[MCBSPLP_SPCR2_REG](#)[7] FRST bit=0).

21.4.3.2.1 Choosing the Width of the Frame-sync Pulse

Each pulse on FSG has a programmable width. You program the McBSPi.[MCBSPLP_SRGR1_REG](#)[15:8] FWID field, and the resulting pulse width is (FWID+1)CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 256 clock periods.

21.4.3.2.2 Controlling the Period Between the Starting Edges of Frame Sync Pulses

You can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the SRG:

- If the SRG is using an external input clock and McBSPi.[MCBSPLP_SRGR2_REG](#)[15] GSYNC bit =1, FSG pulses in response to an inactive-to-active transition on the mcbspi_fsr pin. Thus, an external device controls the frame-synchronization period.

- Otherwise, the software program the McBSPi.[MCBSPLP_SRGR2_REG\[11:0\]](#) FPER field, and the resulting frame-synchronization period is (FPER+1)CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 4096 clock periods.

21.4.3.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the SRG, the McBSPi.[MCBSPLP_SRGR2_REG\[15\]](#) GSYNC bit and the `mcbspi_fsr` pin can be used to configure the timing of FSG pulses.

McBSPi.[MCBSPLP_SRGR2_REG\[15\]](#) GSYNC=1 ensures that the McBSP module and an external device are dividing down the input clock with the same phase relationship.

If McBSPi.[MCBSPLP_SRGR2_REG\[15\]](#) GSYNC=1, an inactive-to-active transition on the `mcbspi_fsr` pin triggers a resynchronization of CLKG and generation of FSG.

21.4.3.3 Synchronizing SRG Outputs to an External Clock

The SRG can produce a clock signal (CLKG) and a FSG based on an input clock signal that is either the interface clock signal (McBSPi_ICLK), or the CLKS signal (PRCM functional clock or `mcbsp_clks`), or a signal at the `mcbspi_clk`, or `mcbspi_clkx` pin. When an external clock (`mcbsp_clks`, or `mcbspi_clk`, or `mcbspi_clkx`) is selected to drive the SRG, the McBSPi.[MCBSPLP_SRGR2_REG\[15\]](#) GSYNC bit and the `mcbspi_fsr` pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock. Make GSYNC=1 so that the McBSP module and an external device divide down the input clock with the same phase relationship.

If the McBSPi.[MCBSPLP_SRGR2_REG\[15\]](#) GSYNC bit=1:

- An inactive-to-active transition on the `mcbspi_fsr` pin triggers a resynchronization of CLKG signal and a pulsing of FSG signal.
- CLKG signal always begins with a high state after synchronization.
- FSR signal is always detected at the same edge of the input clock signal that generates CLKG signal, no matter how long the FSR pulse is.
- The McBSPi.[MCBSPLP_SRGR2_REG\[11:0\]](#) FPER field are ignored because the frame-synchronization period on FSG is determined by the arrival of the next frame-synchronization pulse on the `mcbspi_fsr` pin.

If the McBSPi.[MCBSPLP_SRGR2_REG\[15\]](#) GSYNC bit=0, CLKG signal runs freely and is not resynchronized, and the frame-synchronization period on FSG signal is determined by McBSPi.[MCBSPLP_SRGR2_REG\[11:0\]](#) FPER field.

21.4.3.3.1 Operating the Transmitter Synchronously with the Receiver

When the McBSPi.[MCBSPLP_SRGR2_REG\[15\]](#) GSYNC bit = 1, the transmitter can operate synchronously with the receiver, provided that the FSX signal is programmed to be driven by FSG signal (McBSPi.[MCBSPLP_SRGR2_REG\[12\]](#) FSGM = 1 and McBSPi.[MCBSPLP_PCR_REG\[11\]](#) FSXM = 1). If the FSR input signal has appropriate timing so that it can be sampled by the falling edge of CLKG signal, it can be used, instead, by setting McBSPi.[MCBSPLP_PCR_REG\[11\]](#) FSXM=0 and connecting FSR signal to FSX externally.

The SRG clock drives the transmit and receive clocking (McBSPi.[MCBSPLP_PCR_REG\[8\]](#) CLKRM bit and McBSPi.[MCBSPLP_PCR_REG\[9\]](#) CLKXM bit are set to 1). Therefore, the CLK(R/X) pin must not be driven by any other driving source.

21.4.3.3.2 Synchronization Examples

[Figure 21-40](#) and [Figure 21-41](#) show the clock and frame-synchronization operation with various polarities of CLKS (the chosen input clock) and FSR signals. These figures assume McBSPi.[MCBSPLP_SRGR1_REG\[15:8\]](#) FWID = 0x0, for an FSG pulse that is one CLKG cycle wide. The McBSPi.[MCBSPLP_SRGR2_REG\[11:0\]](#) FPER field are not programmed; the period from the start of a frame-synchronization pulse to the start of the next pulse is determined by the arrival of the next inactive-to-active transition on the `mcbspi_fsr` pin.

Each figure shows what happens to CLKG signal when the McBSPi.[MCBSPLP_SRGR2_REG\[15\]](#) GSYNC bit = 1 and if it is initially synchronized or if it is not initially synchronized. [Figure 21-41](#) has a slower CLKG frequency (it has a larger divide-down value in the McBSPi.[MCBSPLP_SRGR1_1_REG\[7:0\]](#) CLKGDV field).

Figure 21-40. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x1)

Figure 21-41. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x3)

21.4.4 McBSP Exception/Error Conditions

21.4.4.1 Introduction

There are several serial port events that can constitute a system error. Any error conditions can be a source of an interrupt:

- Receiver overrun (McBSPi.[MCBSPLP_IRQSTATUS_REG\[5\]](#) ROVFLSTAT bit is set to 1, and legacy mode McBSPi.[MCBSPLP_SPCR1_REG\[2\]](#) RFULL bit is set to 1)

This occurs when RB is full and RSR are full with another new word shifted in from mcbspi_dr. Therefore, McBSPi.[MCBSPLP_IRQSTATUS_REG\[5\]](#) ROVFLSTAT

(McBSPi.[MCBSPLP_SPCR1_REG\[2\]](#) RFULL) indicates an error condition wherein any new data that can arrive at this time on mcbspi_dr replaces the contents of the RSR, and the previous word is lost.

The RSR continues to be overwritten as long as new data arrives on mcbspi_dr and

McBSPi.[MCBSPLP_DRR_REG](#) register is not read. For more details about overrun in the receiver, see [Section 21.4.4.2](#).

- Unexpected receive frame-synchronization pulse (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[0] RSYNCERR bit is set to 1, and legacy mode McBSPi.[MCBSPLP_SPCR1_REG](#)[3] RSYNCERR bit is set to 1).
 This occurs during reception when an unexpected frame-synchronization pulse arrives. An unexpected frame-synchronization pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been received. Such a pulse is ignored by the receiver, but sets the McBSPi.[MCBSPLP_SPCR1_REG](#)[3] RSYNCERR bit. For more details about receive frame-synchronization errors, see [Section 21.4.4.3, Unexpected Receive Frame-Sync Pulse](#).
- Receiver underflow (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[4] RUNDLSTAT bit is set to '1')
 This occurs when sDMA controller or MPU/IVA2.2 subsystem reads data from an empty receive buffer. For more details about underflow in the receiver, see [Section 21.4.4.4](#).
- Transmitter underflow (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[11] XUNDFLSTAT bit is set to '1', and legacy mode McBSPi.[MCBSPLP_SPCR2_REG](#)[2] XEMPTY bit is set to '0')
 If a new frame-synchronization signal arrives when XB is empty, the previous data in the XSR is sent again. This procedure continues for every new frame-synchronization pulse that arrives until McBSPi.[MCBSPLP_DXR_REG](#) register is loaded with new data (and the XB is no longer empty). For more details about underflow in the transmitter, see [Section 21.4.4.5](#).
- Unexpected transmit frame-synchronization pulse (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[7] XSYNCERR bit is set to '1', and legacy mode McBSPi.[MCBSPLP_SPCR2_REG](#)[3] XSYNCERR bit is set to '1')
 This occurs during transmission when an unexpected frame-synchronization pulse arrives. An unexpected pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been transferred. Such a pulse is ignored by the transmitter, but sets the McBSPi.[MCBSPLP_SPCR2_REG](#)[3] XSYNCERR bit. For more details see [Section 21.4.4.6](#).
- Transmitter overflow (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[12] XOVFLSTAT bit is set to '1')
 This occurs when sDMA controller or MPU/IVA2.2 subsystem writes data to a full XB. For more details about underflow in the receiver, see [Section 21.4.4.7](#).

21.4.4.2 Overrun in the Receiver

When McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[5] ROVFLSTAT bit set to '1', and McBSPi.[MCBSPLP_SPCR1_REG](#)[2] RFULL bit set to '1' (legacy mode) indicates that the receiver has experienced overrun and is in an error condition. Receive overrun is set when all of the following conditions are met:

1. McBSPi.[MCBSPLP_DRR_REG](#) is not read even if the McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[3] RRDY bit is set (legacy mode) and DMA or interrupt request has been asserted.
2. RB is full
3. RSR is full

As previously described, data arriving on `mcbspi_dr` is continuously shifted into the Receive Shift Register (RSR). Once a complete word is shifted into the RSR, an RSR-to-RB copy can occur only if the RB is not full.

Either of the following events clears the legacy mode McBSPi.[MCBSPLP_SPCR1_REG](#)[2] RFULL bit and allows subsequent transfers to be read properly:

- The MPU/IVA2.2 subsystems or sDMA controller reads McBSPi.[MCBSPLP_DRR_REG](#).
- The receiver is reset individually (McBSPi.[MCBSPLP_SPCR1_REG](#)[0] RRST bit =0) or as part of a global reset.

Another frame-synchronization pulse is required to restart the receiver.

According to the McBSPi.[MCBSPLP_IRQENABLE_REG](#) register setting, this condition can generate the McBSPi.[IRQ](#) line to be asserted low. Writing 1 to the corresponding bit in McBSPi.[MCBSPLP_IRQSTATUS_REG](#) register clears the interrupt.

[Figure 21-42](#) shows the receive overrun condition.

Figure 21-42. Overrun in the McBSP Receiver

21.4.4.3 Unexpected Receive Frame-sync Pulse

21.4.4.3.1 Possible Responses to Receive Frame-sync Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse, and the receiver sets the receive frame-synchronization error bit [McBSPi.MCBSPPLP_IRQSTATUS_REG\[0\]](#) RSYNCERR (and the legacy [McBSPi.MCBSPPLP_SPCR1_REG\[3\]](#) RSYNCERR bit).

According to the [McBSPi.MCBSPPLP_IRQENABLE_REG](#) register settings this condition can generate the [McBSPi.IRQ](#) line to be asserted low. Writing 1 to the corresponding bit in [McBSPi.MCBSPPLP_IRQSTATUS_REG](#) register clears the interrupt.

Using the legacy mode, [McBSPi.MCBSPPLP_SPCR1_REG\[3\]](#) RSYNCERR bit can be cleared only by a receiver reset or by writing 0 to this bit. If you want the McBSP module to notify the MPU/IVA2.2 subsystem of receive frame-synchronization errors, set the legacy mode receive interrupt with the [McBSPi.MCBSPPLP_SPCR1_REG\[5:4\]](#) RINTM bit field. When RINTM = 0b11, the McBSP module sends a receive interrupt (legacy mode) request to the MPU/IVA2.2 subsystems each time that RSYNCERR is set.

21.4.4.3.2 Example of an Unexpected Receive Frame-sync Pulse

[Figure 21-43](#) shows an unexpected receive frame-synchronization pulse during normal operation of the serial port, with time intervals between data packets.

NOTE: The unexpected receive frame-synchronization pulse does not influence the data receive process, being ignored by the data receive state-machine.

Figure 21-43. Unexpected Frame-sync Pulse During a McBSP Reception

21.4.4.3.3 Preventing Unexpected Receive Frame-sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKR cycles, depending on the value of the [McBSPi.MCBSPPLP_RCR2_REG\[1:0\]](#) RDATDLY field. For each possible data delay, [Figure 21-44](#) shows when a new frame-synchronization pulse on FSR can safely occur relative to the last bit of the current frame.

Figure 21-44. Proper Positioning of Receive Frame-sync Pulses

mcbsp-039

21.4.4.4 Underflow in the Receiver

The McBSP module indicates a receiver underflow condition by setting the McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[4] RUNDLSTAT bit. This error occurs when sDMA controller or MPU/IVA2.2 subsystem reads data from an empty RB this happens only if the MPU/IVA2.2 subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request, or does not check the buffer status before reading data. According to the McBSPi.[MCBSPLP_IRQENABLE_REG](#) register settings this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.[MCBSPLP_IRQSTATUS_REG](#) register clears the interrupt.

21.4.4.5 Underflow in the Transmitter

The McBSP module indicates a transmitter empty (or underflow) condition by setting the McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[11] XUNDLSTAT bit. Also the legacy mode McBSPi.[MCBSPLP_SPCR2_REG](#)[2] XEMPTY bit is cleared. Either of the following events activates XEMPTY bit (XEMPTY = 0):

- McBSPi.[MCBSPLP_DXR_REG](#) has not been loaded and XB is empty, and all bits of the data word in the XSR have been shifted out on the mcbspi_dx pin.
- The transmitter is reset (by forcing McBSPi.[MCBSPLP_SPCR2_REG](#)[0] XRST=0, or by a global reset) and is then restarted.

XEMPTY bit is deactivated (XEMPTY=1) when a new word in McBSPi.[MCBSPLP_DXR_REG](#) is transferred to Transmit Buffer (XB). If McBSPi.[MCBSPLP_PCR_REG](#)[11] FSXM=1 and McBSPi.[MCBSPLP_SRGR2_REG](#)[12] FSGM=0, the transmit frame-sync signal (FSX) is generated when Transmit Buffer (XB) is not empty. When McBSPi.[MCBSPLP_SRGR2_REG](#)[12] FSGM=0, McBSPi.[MCBSPLP_SRGR2_REG](#)[11:0] FPER and McBSPi.[MCBSPLP_SRGR1_REG](#)[15:8] FWID are used to determine the frame-synchronization period and width (external FSX is gated by the buffer empty condition). Otherwise, the transmitter waits for the next frame-synchronization pulse before sending out the next frame on mcbspi_dx.

When the transmitter is taken out of reset (McBSPi.[MCBSPLP_SPCR2_REG](#)[0] XRST=1), it is in a transmitter ready state (McBSPi.[MCBSPLP_SPCR2_REG](#)[1] XRDY bit =1) and transmitter empty (McBSPi.[MCBSPLP_SPCR2_REG](#)[2] XEMPTY=0) state. If McBSPi.[MCBSPLP_DXR_REG](#) is loaded by

the MPU/IVA2.2 subsystem or the sDMA controller before internal FSX goes active high, a valid XB-to-XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-synchronization pulse is generated or detected. Alternatively, if a transmit frame-synchronization pulse is detected before McBSPi.[MCBSPLP_DXR_REG](#) is loaded, zeros are output on mcbspi_dx.

The McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[11] XUNDLSTAT bit indicates a real underflow condition, in which the frame is corrupted due to lack of data availability during transmit process. According to the McBSPi.[MCBSPLP_IRQENABLE_REG](#) register settings this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.[MCBSPLP_IRQSTATUS_REG](#) register clears the interrupt.

21.4.4.6 Unexpected Transmit Frame-sync Pulse

21.4.4.6.1 Possible Responses to Transmit Frame-sync Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse, and the transmitter sets the transmit frame-synchronization error bit McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[7] XSYNCERR (and the legacy McBSPi.[MCBSPLP_SPCR2_REG](#)[3] XSYNCERR bit).

According to the McBSPi.[MCBSPLP_IRQENABLE_REG](#) register settings, this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in status register clears the interrupt.

Using the legacy mode, McBSPi.[MCBSPLP_SPCR2_REG](#)[3] XSYNCERR bit can be cleared only by a transmitter reset or by a write of 0 to this bit. If you want the McBSP module to notify the MPU/IVA2.2 subsystem of frame-synchronization errors, you can set a special transmit interrupt mode with the McBSPi.[MCBSPLP_SPCR2_REG](#)[5:4] XINTM field. When XINTM=0b11, the McBSP module sends a transmit interrupt request to the MPU/IVA2.2 subsystem each time that XSYNCERR is set.

21.4.4.6.2 Example of Unexpected Transmit Frame-Synchronization Pulse

Figure 21-45 shows an unexpected transmit frame-synchronization pulse during normal operation of the serial port with intervals between the data packets.

NOTE: The unexpected transmit frame-synchronization pulse does not influence the data transmit process, being ignored by the data transmit state-machine.

Figure 21-45. Unexpected Frame-sync Pulse During a McBSP Transmission

21.4.4.6.3 Preventing Unexpected Transmit Frame-sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the McBSPi.[MCBSPLP_XCR2_REG](#)[1:0] XDATDLY field. For each possible data delay, Figure 21-46 shows when a new frame-synchronization pulse on FSX can safely occur relative to the last bit of the current frame.

Figure 21-46. Proper Positioning of Transmit Frame-sync Pulses

mcbsp-041

21.4.4.7 Overflow in the Transmitter

The McBSP module indicates a transmitter overflow condition by setting the McBSPi.[MCBSPLP_IRQSTATUS_REG\[12\]](#) XOVFLSTAT bit. This error occurs when sDMA controller or MPU/IVA2.2 subsystem write data to a full XB (this may happen only if the MPU/IVA2.2 subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request or does not check the buffer status before writing data). According to the McBSPi.[MCBSPLP_IRQENABLE_REG](#) register settings this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in status register clears the interrupt.

21.4.5 McBSP DMA Configuration

The McBSP receive and transmit data DMA requests are active after the receive McBSPi.[MCBSPLP_SPCR1_REG\[0\]](#) RRST and transmit McBSPi.[MCBSPLP_SPCR2_REG\[0\]](#) XRST are released. After reset the default DMA threshold (and length) is one.

The receive and transmit DMA requests can be individually disabled by setting the McBSPi.[MCBSPLP_RCCR_REG\[3\]](#) RDMAEN, McBSPi.[MCBSPLP_XCCR_REG\[3\]](#) XDMAEN bits to 0. When disabling the DMA, the DMA request line is de-asserted even if a DMA transfer is pending and the DMA state-machine is not reset.

The DMA threshold and length configuration is done through McBSPi.[MCBSPLP_THRSH1_REG](#) and McBSPi.[MCBSPLP_THRSH2_REG](#) registers as follows:

- (THRSH1_REG + 1) value represents the required receive DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the RB occupied locations level is above or equal to the THRSH1_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH1_REG + 1) number of words, the receive DMA request is de-asserted and reasserted as soon as the conditions are met again.
- (THRSH2_REG + 1) value represents the required transmit DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the XB free locations level is above or equal to the THRSH2_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH2_REG + 1) number of words, the transmit DMA request is de-asserted and reasserted as soon as the conditions are met again.

NOTE: The MPU/IVA2.2 subsystem can decide not to use the DMA to transfer the data. In this case, the DMA must be disabled (or the DMA request can be ignored by MPU/IVA2.2 subsystem) and the common interrupt line (McBSPi_IRQ) can be used. The McBSPi.MCBSPPLP_SPCR1_REG[1] RRDY bit for receive and McBSPi.MCBSPPLP_SPCR2_REG[1] XRDY bit for transmit will indicate when the threshold values are reached. Also, by reading the receive buffer status McBSPi.MCBSPPLP_RBUFFSTAT_REG register and transmit buffer status McBSPi.MCBSPPLP_XBUFFSTAT_REG register, the MPU/IVA2.2 subsystem can decide to transfer data even if the threshold is not reached. This mechanism is useful on the last transfer on receive side when the threshold value is bigger than the occupied locations inside the receive buffer and the MPU/IVA2.2 subsystem needs to read this data. Since no interrupt or DMA request is asserted the only option in this case is to read the RB status register value and to transfer the remaining data without using the DMA or interrupt indication.

21.4.6 Multichannel Selection Modes

21.4.6.1 Channels, Blocks, and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. The McBSP module supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that contain 16 contiguous channels each:

- Block 0: Channels 0–15
- Block 1: Channels 16–31
- Block 2: Channels 32–47
- Block 3: Channels 48–63
- Block 4: Channels 64–79
- Block 5: Channels 80–95
- Block 6: Channels 96–111
- Block 7: Channels 112–127

The blocks are assigned to partitions according to the selected partition mode. In the two-partition mode described in [Section 21.4.6.6](#), you assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) to partition B. In the 8-partition mode [Section 21.4.6.4](#), blocks 0 through 7 are automatically assigned to partitions A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent of each other. For example, it is possible to use two receive partitions (A and B) and eight transmit partitions (A–H).

21.4.6.2 Multichannel Selection

When a McBSP module uses a time-division multiplexed (TDM) data stream while communicating with other McBSP modules or serial devices, the McBSP module may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, use a multichannel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP module has one receive multichannel selection mode [Section 21.4.6.5](#), and three transmit multichannel selection modes [Section 21.4.6.7](#).

21.4.6.3 Configuring a Frame for Multichannel Selection

Before enabling a multichannel selection mode, make sure you properly configure the data frame:

- Select a single-phase frame (McBSPi.MCBSPPLP_RCR2_REG[15] RPHASE bit and McBSPi.MCBSPPLP_XCR2_REG[15] XPHASE bit = 0). Each frame represents a TDM data stream.

- Set a frame length (in McBSPi.[MCBSPLP_RCR1_REG](#)[14:8] RFRLEN1 field and in McBSPi.[MCBSPLP_XCR1_REG](#)[14:8] XFRLEN1 field) that includes the highest-numbered channel to be used. For example, if you plan to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFRLEN1 = 39). If RFRLEN1 = 39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

21.4.6.4 Using Eight Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use eight partitions or two partitions (as previously described). If you choose the 8-partition mode (McBSPi.[MCBSPLP_MCR1_REG](#)[9] RMCME = 1 for reception, McBSPi.[MCBSPLP_MCR2_REG](#)[9] XMCME = 1 for transmission), McBSP channels are activated in the following order: A, B, C, D, E, F, G, H.

In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In the 8-partition mode, the McBSPi.[MCBSPLP_MCR1_REG](#)[6:5] RPABLK and McBSPi.[MCBSPLP_MCR2_REG](#)[6:5] XPABLK, and McBSPi.[MCBSPLP_MCR1_REG](#)[8:7] RPBBLK and McBSPi.[MCBSPLP_MCR2_REG](#)[8:7] XPBBLK bit fields are ignored, and the 16 channel blocks are assigned to the partitions as shown in [Table 21-20](#) through [Table 21-21](#). These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

Table 21-20. Eight Partitions – Receive Channel Assignment and Control

Receive Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: Channels 0 through 15	McBSPi. MCBSPLP_RCERA_REG
B	Block 1: Channels 16 through 31	McBSPi. MCBSPLP_RCERB_REG
C	Block 2: Channels 32 through 47	McBSPi. MCBSPLP_RCERC_REG
D	Block 3: Channels 48 through 63	McBSPi. MCBSPLP_RCERD_REG
E	Block 4: Channels 64 through 79	McBSPi. MCBSPLP_RCERE_REG
F	Block 5: Channels 80 through 95	McBSPi. MCBSPLP_RCERF_REG
G	Block 6: Channels 96 through 111	McBSPi. MCBSPLP_RCERG_REG
H	Block 7: Channels 112 through 127	McBSPi. MCBSPLP_RCERH_REG

Table 21-21. Eight Partitions – Transmit Channel Assignment and Control

Transmit Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: Channels 0 through 15	McBSPi. MCBSPLP_XCERA_REG
B	Block 1: Channels 16 through 31	McBSPi. MCBSPLP_XCERB_REG
C	Block 2: Channels 32 through 47	McBSPi. MCBSPLP_XCERC_REG
D	Block 3: Channels 48 through 63	McBSPi. MCBSPLP_XCERD_REG
E	Block 4: Channels 64 through 79	McBSPi. MCBSPLP_XCERE_REG
F	Block 5: Channels 80 through 95	McBSPi. MCBSPLP_XCERF_REG
G	Block 6: Channels 96 through 111	McBSPi. MCBSPLP_XCERG_REG
H	Block 7: Channels 112 through 127	McBSPi. MCBSPLP_XCERH_REG

Figure 21-47 shows an example of the McBSP using the 8-partition mode. In response to a frame-synchronization pulse, the McBSP module begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

Figure 21-47. McBSP Data Transfer in 8-Partition Mode

21.4.6.5 Receive Multichannel Selection Mode

The McBSPi.[MCBSPLP_MCR1_REG\[0\]](#) RMCM bit determines whether all channels or only selected channels are enabled for reception.

- When RMCM = 0, all 128 receive channels are enabled and cannot be disabled.
- When RMCM = 1, the receive multichannel selection mode is enabled. In this mode:
 - Channels can be individually enabled or disabled. The enabled channels are those selected in the appropriate receive channel enable registers (McBSPi.[MCBSPLP_RCERA_REG](#) to McBSPi.[MCBSPLP_RCERH_REG](#)). The channels are assigned to the McBSPi.[MCBSPLP_RCERA_REG](#) to McBSPi.[MCBSPLP_RCERH_REG](#) registers depends on the number of receive channel partitions (2 or 8), as defined by the McBSPi.[MCBSPLP_MCR1_REG\[9\]](#) RMCME bit.
 - If a receive channel is disabled, any bits received in that channel are not transferred to the RB, and as a result, the receiver ready bit (RRDY) is not set. Therefore, no DMA synchronization event is generated and, if the receiver interrupt mode depends on RRDY (McBSPi.[MCBSPLP_SPCR1_REG\[5:4\]](#) RINTM = 0b00), no interrupt is generated.

As an example of how the McBSP module behaves in the receive multichannel selection mode, suppose you enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP module:

1. Accepts bits shifted in from the mcbspi_dr pin in channel 0
2. Ignores bits received in channels 1–14
3. Accepts bits shifted in from the mcbspi_dr pin in channel 15
4. Ignores bits received in channels 16–38
5. Accepts bits shifted in from the mcbspi_dr pin in channel 39

21.4.6.6 Using Two Partitions (Legacy Only)

For multichannel selection operation in the receiver and/or the transmitter, you can use two partitions or eight partitions. If you choose the 2-partition mode (McBSPi.[MCBSPLP_MCR1_REG\[9\]](#) RMCME = 0 for reception, McBSPi.[MCBSPLP_MCR2_REG\[9\]](#) XMCME = 0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred beginning with the channels in partition A.

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point. Similarly, any two of the eight transmit-channel blocks (up 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the McBSPi.[MCBSPLP_MCR1_REG](#)[6:5] RPABLK field. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register A (McBSPi.[MCBSPLP_RCERA_REG](#)).
 - Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the McBSPi.[MCBSPLP_MCR1_REG](#)[8:7] RPBLBK field. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register B (McBSPi.[MCBSPLP_RCERB_REG](#)).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the McBSPi.[MCBSPLP_MCR2_REG](#)[6:5] XPABLK fields. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register A (McBSPi.[MCBSPLP_XCERA_REG](#)).
 - Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the McBSPi.[MCBSPLP_MCR1_REG](#)[8:7] XPBBLK field. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register B (McBSPi.[MCBSPLP_XCERB_REG](#)).

[Figure 21-48](#) shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0–15 have been assigned to partition A, and channels 16–31 have been assigned to partition B. In response to a frame-synchronization pulse, the McBSP module begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

Figure 21-48. Alternating Between Partitions A and B Channels

Slot	Partition	Block	Channel
1	A	0	0-15
2	B	1	16-31
3	A	0	0-15
4	B	1	16-31
5	A	0	0-15
6	B	1	16-31
7	A	0	0-15
8	B	1	16-31
9	A	0	0-15
10	A	0	0-15

21.4.6.7 Transmit Multichannel Selection Modes

The McBSPi.MCBSPPLP_MCR2_REG[1:0] XMCM field determine whether all channels or only selected channels are enabled and unmasked for transmission. The McBSP module has three transmit multichannel selection modes (XMCM = 0b01, XMCM = 0b10, and XMCM = 0b11), which are described in Table 21-22.

Table 21-22. Selecting a Transmit Multichannel Selection Mode With the XMCM Bit Field

XMCM	Transmit Multichannel Selection Mode
0b00	No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
0b01	All channels are disabled unless they are selected in the appropriate transmit channel enable registers (McBSPi. MCBSPLP_XCERA_REG /McBSPi. MCBSPLP_XCERH_REG). If enabled, a channel in this mode is also unmasked. The McBSPi. MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in the McBSPi. MCBSPLP_XCERA_REG /McBSPi. MCBSPLP_XCERH_REG registers.
0b10	All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (McBSPi. MCBSPLP_XCERA_REG /McBSPi. MCBSPLP_XCERH_REG). The McBSPi. MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in the McBSPi. MCBSPLP_XCERA_REG /McBSPi. MCBSPLP_XCERH_REG registers.
0b11	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (McBSPi. MCBSPLP_RCERA_REG /McBSPi. MCBSPLP_RCERH_REG). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (McBSPi. MCBSPLP_XCERA_REG /McBSPi. MCBSPLP_XCERH_REG). The McBSPi. MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in McBSPi. MCBSPLP_RCERA_REG /McBSPi. MCBSPLP_RCERH_REG registers and McBSPi. MCBSPLP_XCERA_REG /McBSPi. MCBSPLP_XCERH_REG registers.

As an example of how the McBSP module behaves in a transmit multichannel selection mode, suppose that XMCM = 0b01 (all channels disabled unless individually enabled) and that you have enabled only channels 0, 15, and 39. Suppose also that the frame length is 40. The McBSP module:

1. Shifts data to the mcbspi_dx pin in channel 0
2. Places the mcbspi_dx pin in the high impedance state in channels 1–14
3. Shifts data to the mcbspi_dx pin in channel 15
4. Places the mcbspi_dx pin in the high impedance state in channels 16–38
5. Shifts data to the mcbspi_dx pin in channel 39

21.4.6.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The definitions in [Table 21-23](#) explain the channel control options:

Table 21-23. McBSP Channel Control Options

Enabled channel	A channel that can begin transmission by passing data from the data transmit register (McBSPi.MCBSPPLP_DXR_REG) to the XSR through XB.
Masked channel	A channel that cannot complete transmission. The mcbspi_dx pin is held in the high impedance state; data cannot be shifted out on the mcbspi_dx pin. In systems where symmetric transmit and receive provide software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.
Disabled channel	A channel that is not enabled. A disabled channel is also masked. Because no DXR-to-XB copy occurs, the McBSPi.MCBSPPLP_SPCR2_REG[1] XRDY bit is not set. Therefore, no DMA synchronization event is generated, and if the transmit interrupt mode depends on XRDY (McBSPi.MCBSPPLP_SPCR2_REG[5:4] XINTM = 00b), no interrupt is generated. The McBSPi.MCBSPPLP_SPCR2_REG[2] XEMPTY bit is not affected.
Unmasked channel	A channel that is not masked. Data in the XSR(s) is shifted out on the mcbspi_dx pin.

21.4.6.7.2 Activity on McBSP Pins for Different Values of XMCM

[Figure 21-49](#) shows the activity on the McBSP pins for the various McBSPi.[MCBSPLP_MCR2_REG\[1:0\]](#) XMCM values. In all cases, the transmit frame is configured as follows:

- XPHASE=0: Single-phase frame (required for multichannel selection modes)
- XFRLEN1=0b0000011: 4 words per frame
- XWDLEN1=0b000: 8 bits per word
- XMCME=0: 2-partition mode (only partitions A and B used)

In the case where McBSPi.[MCBSPLP_MCR2_REG\[1:0\]](#) XMCM=0b11, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLEN1, and XWDLEN1, respectively.

In [Figure 21-49](#), the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

Figure 21-49. Activity on McBSP Pins When XMCM=0b00

If XMCM = 0b00, all channels are enabled and unmasked. Words W0, W1, W2, and W3 are written to the XB, then, from the XB, there are transferred by mcbspi_dx.

Figure 21-50. Activity on McBSP Pins When XMCM=0b01

In [Figure 21-50](#) if XMCM = 0b01, XPABLK = 0b00, and XCERA = 0b1010, only channels 1 and 3 are enabled and unmasked. Words W1 and W3 are written to the XB, then, from the XB, there are transferred by mcbspi_dx.

Figure 21-51. Activity on McBSP Pins When XMCM=0b10

In [Figure 21-51](#) if XMCM = 0b10, XPABLK = 0b00, and XCERA = 0b1010, all channels are enabled, only 1 and 3 unmasked. Words W0, W1, W2, and W3 are written to the XB, but only W1 and W3, from the XB, there are transferred by mcbspi_dx.

Figure 21-52. Activity on McBSP Pins When XMCM=0b11

mcbsp-047

In Figure 21-52 if XMCM = 0b11, RPABLK = 0b00, XPABLK = 0bX, RCERA = 0b1010 and XCERA = 0b1000, channels 1 and 3 are enabled in receive and transmit mode, but only 3 unmasked. Words W1 and W3 are written to the XB, but only W3, from the XB, there are transferred by mcbspi_dx.

21.4.7 SIDETONE Mode (ALP)

21.4.7.1 Introduction

In multimedia-rich mobile communication devices, loopback signals from audio inputs to audio outputs are renamed. A traditional example is the telephone SIDETONE (that is, the telephone user expects to also hear his own voice in the earpiece).

Some of the features using the loopback have strict delay requirements.

It is required that two of the audio input channels be looped back, filtered, and mixed to the corresponding two audio output channels. The SIDETONE mode filters and applies gain to each sample received.

21.4.7.2 SIDETONE Interface

The data from digital microphone, two (out of four) channels, can be configured to be input in the external SIDETONE core. After filtering, the data from digital microphone data is mixed and sent out to the speaker output channels using two (out of eight) configured output channels (separate configuration bits are used). The McBSP module synchronizes the incoming data (filtered by the external SIDETONE core). The transmit and receive part of the McBSP module are not required to operate on the same functional frequency.

The SIDETONE interface offers the following features:

- Send out two 24-bit data channels for the configured SIDETONE received channels (channels can be the same)
- Send out two control signals to indicate to the SIDETONE module that the data is valid (toggle signals which are changing the value from 0 to 1 or 1 to 0 each time a new data is available)
- Receive two 24-bit filtered data channels from the external SIDETONE module and send these channels to the configured transmit channels after mixing the data with the incoming data (from the L4 interface). The sum between the incoming data and SIDETONE loopback data is a saturated sum.
- Receive two control signals to indicate that the SIDETONE module filtered data is available (toggle signals which are changing the value from 0 to 1 or 1 to 0 each time a new data is available).

Figure 21-53 shows the SIDETONE external module data path:

Figure 21-53. SIDETONE Data Path

mcbsp-048

Before you enable a SIDETONE selection mode, make sure you properly configure the data frame for multichannel and SIDETONE mode:

- Select a single-phase frame (McBSPi.[MCBSPLP_RCR2_REG\[15\]](#) RPHASE bit and McBSPi.[MCBSPLP_XCR2_REG\[15\]](#) XPHASE bit=0). Each frame represents a TDM data stream.
- Set McBSPi.[MCBSPLP_MCR1_REG\[0\]](#) RMCM=1 to select multichannel mode enable.
- Set a frame length (in McBSPi.[MCBSPLP_RCR1_REG\[14:8\]](#) RFRLEN1 bit field and in McBSPi.[MCBSPLP_XCR1_REG\[14:8\]](#) XFRLEN1 bit field) that includes the highest-numbered channel to be used (a maximum of 4 channels can be used in this configuration).
- Set a word length (in McBSPi.[MCBSPLP_RCR1_REG\[7:5\]](#) RWDLEN1 bit field and in McBSPi.[MCBSPLP_XCR1_REG\[7:5\]](#) XWDLEN1 bit field) to be either 16, 24 or 32 (see note).
- Select the input/output channels configured as SIDETONE channels and enable SIDETONE by setting the McBSPi.[MCBSPLP_SSELCR_REG\[1:0\]](#) ICH0ASSIGN/McBSPi.[MCBSPLP_SSELCR_REG\[6:4\]](#) OCH0ASSIGN , McBSPi.[MCBSPLP_SSELCR_REG\[3:2\]](#) ICH1ASSIGN/McBSPi.[MCBSPLP_SSELCR_REG\[9:7\]](#) OCH1ASSIGN fields (2 out of 4 channels external SIDETONE assignment) and McBSPi.[MCBSPLP_SSELCR_REG\[10\]](#) SIDETONEEN bit to 1.

NOTE: Word width in the loop is 24 bits. If input channel word width is less than 24 bits, LSBs of the samples are zero padded. If input channel word width is more than 24 bits, samples are truncated.

Figure 21-54 describes the data exchange protocol between McBSP module and SIDETONE core:

Figure 21-54. McBSP to SIDETONE Data Exchange

mcbsp-049

[Figure 21-55 describes the data exchange protocol between SIDETONE core and McBSP module:](#)

Figure 21-55. SIDETONE to McBSP Data Exchange

mcbsp-050

NOTE: To use the same input channel as source for both SIDETONE output channels the McBSPi.MCBSPPLP_SSELCR_REG[1:0] ICH0ASSIGN should be equal to McBSPi.MCBSPPLP_SSELCR_REG[3:2] ICH1ASSIGN. The McBSP module does not support two input channels to be assigned to only one SIDETONE output channel.

21.4.7.3 Data Processing Path

The SIDETONE core receives the data to be processed through two 24-bits parallel data interfaces, one for each audio channel. When enabled through McBSPi.[ST_SSELCR_REG\[0\]](#) SIDETONEEN bit-field, the module applies the filtering and gain functions to each data item (frame) and outputs it through two similar 24-bits parallel data interfaces.

[Figure 21-56 below describes how the data is sampled and output through the dedicated data interfaces.](#)

Figure 21-56. SIDETONE Processed Data Interfaces

NOTE: The processing time needed is 132 clock cycles (SIDETONE enabled). The total number of cycles needed for outputting the new processed data upon arrival of a sample is maximum 135 (including synchronizations). When not enabled, the data response takes maximum 5 clock cycles.

The ST_CH0_VALIDR and ST_CH1_VALIDR are 1 bit inputs and their toggling information is used to signal that new data is valid for sampling from ST_CH0_DATAR / ST_CH1_DATAR.

The ST_CH0_VALIDX and ST_CH1_VALIDX are 1 bit outputs and their toggling information is used to signal that new data is valid on the output data bus ST_CH0_DATAX / ST_CH1_DATAX.

21.4.7.4 Data Processing

The processing consists in 2 stages filtering and applying gain to signal. The whole process takes 132 clock cycles.

If a new frame comes too early causing the interrupt assertion, the current frame will be completely processed and this new frame will be ignored. Consequent frames will also be ignored until the current frame processing has ended.

21.4.7.4.1 Filtering

A 128 length FIR filter scheme is used. The module must process the two channels in parallel so two instances of filter will work in parallel sharing only the same coefficients.

Samples data are signed values in interval (-1..1) in Q23 format, negative values are expressed in 2's complement. Coefficients are also signed values in interval (-1..1) in Q15 format, negative values are expressed in 2's complement too.

The module handles overflows in the sums of the product but the user should choose the coefficients with the sum of magnitudes in absolute value is smaller than 1, otherwise the user must ensure that gain applying brings the samples value below |1|, to avoid saturation.

$$|C_0| + |C_1| + \dots + |C_{127}| < 1$$

CAUTION

The coefficients cannot be loaded while the filtering is active (SIDETONE enabled).

21.4.7.4.2 Applying Gain

Each output sample will be multiplied with the gain value specified in the McBSPi.[ST_SGAINCR_REG](#). The gain is independent for each channel and can be modified anytime through L4-interface with immediate effect. Gain values are in the interval (-2..2) in Q1.14 format, negative values are expressed in 2's complement.

The user must choose the gain's value according to the magnitude of the samples to avoid overflow in the final product between the FIR data and gain value. If an overflow occurs, the output data is saturated.

21.4.7.4.3 Enabling SIDETONE

When the SIDETONE operation is enabled (McBSPi.[ST_SSELCR_REG\[0\]](#) SIDETONEEN is 1), the module starts collecting samples received through the data interface without returning any sample or toggling any of the ST_CH0/CH1_VALIDX outputs. The first 127 samples for each channel are only accumulated, no processed data is provided. The first processed frame comes after receiving the 128th sample (with the specific delay).

When the SIDETONE operation is disabled, data is output through the data interface as it comes on the data input interface with the resynchronization latency of maximum 5 clock cycles. Re-enabling it requires waiting another 128 samples before providing new processed samples (each transition of McBSPi.[ST_SSELCR_REG\[0\]](#) SIDETONEEN from 0 to 1 triggers this initialization process).

NOTE: After reset, the McBSPi.[ST_SSELCR_REG\[0\]](#) SIDETONEEN bit is 0.

21.4.7.4.4 FIR Accuracy

All the arithmetic inside the module is performed without any truncation/saturation until the last stage – the gain applying, where the result of the product between gain and FIR value is saturated to +/-1 if overflow occurs and the LSBs are truncated.

21.4.7.5 Interrupt Operation

The SIDETONE core has a single interrupt line and a single event that may trigger the interrupt. The event (an error one) occurs when the input interface data rate overflows the processing ability of the module. As described in the data processing path section, the SIDETONE core completes a frame processing in 132 cycles. If the input frame rate for any channel exceeds 1 frame/132 x interface clock period while SIDETONE is enabled , the McBSPi.[ST_IRQSTATUS_REG\[0\]](#) OVRERROR bit in is set and, if McBSPi.[ST_IRQENABLE_REG\[0\]](#) OVRERRROREN bit is set to 1, the interrupt line is asserted.

21.5 McBSP Basic Programming Model

This section describes the programming model of typical McBSP module and SIDETONE core applications.

21.5.1 McBSP Core

CAUTION

For all descriptions in this section, the McBSPi.[MCBSPLP_XCCR_REG\[11\]](#) XFULL_CYCLE bit and the McBSPi.[MCBSPLP_RCCR_REG\[11\]](#) RFULL_CYCLE bit are their reset value (XFULL_CYCLE bit=0 and RFULL_CYCLE bit=1).

21.5.1.1 McBSP Initialization Procedure

This procedure for reset/initialization can be applied in general when the Receiver or Transmitter has to be reset during its normal operation, and also when the Sample Rate Generator is not used for either operation.

Figure 21-57 shows the serial port initialization procedure for master mode.

Figure 21-57. Flow Diagram of McBSP Initialization Procedure for Master Mode

mcbsp-062

Alternatively, on write (step 1 or 4), the transmitter and receiver can be placed in or taken out of reset by modifying the McBSPi.MCBSPPLP_SPCR2_REG[0] XRST bit and the McBSPi.MCBSPPLP_SPCR1_REG[0] RRST bit, respectively.

Figure 21-58 shows the flow diagram of the McBSP initialization procedure for slave mode.

Figure 21-58. Flow Diagram of McBSP Initialization Procedure for Slave Mode

mcbsp-074

NOTE:

- The necessary duration of the active-low period of XRST or RRST is at least two CLKR/CLKX cycles.
- The appropriate bits in serial port configuration registers (McBSPi.[MCBSPLP_SPCR1_REG](#), McBSPi.[MCBSPLP_SPCR2_REG](#), McBSPi.[MCBSPLP_PCR_REG](#), McBSPi.[MCBSPLP_RCR1_REG](#), McBSPi.[MCBSPLP_RCR2_REG](#), McBSPi.[MCBSPLP_XCR1_REG](#), McBSPi.[MCBSPLP_XCR2_REG](#), McBSPi.[MCBSPLP_THRSH2_REG](#), McBSPi.[MCBSPLP_XCCR_REG](#), McBSPi.[MCBSPLP_SYSCONFIG_REG](#), McBSPi.[MCBSPLP_SRGR1_REG](#), and McBSPi.[MCBSPLP_SRGR2_REG](#)) should only be modified when the affected portion of the serial port is in its reset state.
- In most cases, the data transmit register (McBSPi.[MCBSPLP_DXR_REG](#)) should be loaded by the MPU/IVA2 subsystem or the sDMA controller only when the transmitter is enabled (McBSPi.[MCBSPLP_SPCR2_REG](#)[0] XRST = 1). An exception to this rule is when these registers are used for loopback internal data.
- The bits of the channel control registers (McBSPi.[MCBSPLP_MCR1_REG](#), McBSPi.[MCBSPLP_MCR2_REG](#), McBSPi.[MCBSPLP_RCER{A-H}_REG](#) and McBSPi.[MCBSPLP_XCER{A-H}_REG](#)) can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode.
- The SRG is reset by setting McBSPi.[MCBSPLP_SPCR2_REG](#)[6] GRST bit to 0.
- It is not necessary to wait if SRG is not used.
- Modification on-the-fly has no effect if a reset is not done first.

21.5.1.2 Reset and Initialization Procedure for the Sample Rate Generator

To reset and initialize the Sample Rate Generator:

- Place the McBSP Sample Rate Generator in RESET.

During a Global RESET, the Sample Rate Generator, the Receiver, and the Transmitter reset bits (GRST, RRST, and XRST) are automatically forced to '0'. Otherwise, during normal operation, the Sample Rate Generator can be reset by making McBSPi.[MCBSPLP_SPCR2_REG](#)[6] GRST=0, provided that CLKG and/or FSG internal signal is not used by any portion of the McBSP module. Depending on the system needs, the software may also to reset the Receiver (McBSPi.[MCBSPLP_SPCR1_REG](#)[0] RRST=0) and reset the Transmitter (McBSPi.[MCBSPLP_SPCR2_REG](#)[0] XRST bit =0).

- Program the registers that affect the Sample Rate Generator.

Program the Sample Rate Generator registers (McBSPi.[MCBSPLP_SPCR1_REG](#) and McBSPi.[MCBSPLP_SPCR2_REG](#)) as required for your application. Refer to [Figure 21-59](#).

If necessary, other control registers can be loaded with desired values provided the respective portion of the McBSP module (the Receiver or Transmitter) is in reset. [Table 21-24](#) presents the McBSP configuration when one of the clock sources is selected, but others registers can be impacted in function of the user application.

Table 21-24. McBSP Configuration in Function of the SRG Clock Source Selected

SRG Clock Source Selected	Module Configuration	McBSPi. MCBSPLP_PCR_REG Configuration			
		CLKRM bit ⁽¹⁾	CLKXM bit	FSRM bit ⁽¹⁾	FSXM bit
McBSPi_ICLK or CLKS	Master Transmitter and Slave Receiver	0	1	0	1
	Master Receiver and Slave Transmitter	1	0	1	0
	Master Transmitter and Receiver	1	1	1	1
CLKR	Master Transmitter and Slave Receiver	0	1	0	1
CLKX	Master Receiver and Slave Transmitter	1	0	1	0

⁽¹⁾ This configuration is correct if McBSPi.[MCBSPLP_XCCR_REG](#)[5] DLB bit=0x0. When the DLB bit is set to 1, the CLKR clock (not the mcbspi_clk pin) is driven by the CLKX clock, which is based on the CLKXM bit.

After the Sample Rate Generator registers are programmed, wait for 2 CLKSRG cycles. This ensures proper synchronization internally.

- Enable the Sample Rate Generator (take it out of reset).

Set McBSPi.[MCBSPLP_SPCR2_REG](#)[6] GRST bit to1 to enable the Sample Rate Generator.

After the Sample Rate Generator is enabled, wait for 2 CLKG cycles for the Sample Rate Generator logic to stabilize.

On the next rising edge of CLKSRG, the CLKG signal transitions to '1' and starts clocking with a frequency equal to (input clock frequency)/(CLKGDV + 1).

- If necessary, enable the receiver and/or the transmitter.

If necessary, remove the receiver and/or transmitter from reset by setting McBSPi.[MCBSPLP_SPCR1_REG](#)[0] RRST bit and/or McBSPi.[MCBSPLP_SPCR2_REG](#)[0] XRST =1.

Figure 21-59. Flow Diagram for the SRG Registers Programmation

mcbsp-073

The input clock is selected with the McBSPi.[MCBSPLP_PCR_REG\[7\]](#) SCLKME bit and the McBSPi.[MCBSPLP_SRGR2_REG\[13\]](#) CLKSM bit in one of the following configurations (see [Table 21-25](#)):

Table 21-25. Input Clock Selection for Sample Rate Generator

SCLKME bit	CLKSM bit	Input Clock for Sample Rate Generator
0	0	Signal on mcbsp_clks pin
0	1	McBSPi_ICLK clock
1	0	Signal on mcbsp_clk pin
1	1	Signal on mcbsp_clkx pin

21.5.1.3 Data Transfer DMA Request Configuration

To configure the McBSP receive/transmit data DMA requests (McBSPi_DMA_RX and McBSPi_DMA_TX), perform the following procedure:

- Write the receive McBSPi.[MCBSPLP_THRESHOLD1_REG](#) register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the RB occupied locations level is above or equal to the THRSH1_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH1_REG value + 1 number of words, the receive DMA request will be de-asserted and reasserted as soon as the conditions are met again.

NOTE: In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the receive buffer empty condition. When the receive buffer is empty a data transfer access will trigger a receive underflow interrupt, if enabled by McBSPi.[MCBSPLP_IRQENABLE_REG\[4\]](#) RUNDLEN bit.

- Write the transmit McBSPi.[MCBSPLP_THRESHOLD2_REG](#) register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the XB free locations level is above or equal to the THRSH2_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH2_REG value + 1 number of words, the transmit DMA request will be de-asserted and reasserted as soon as the conditions are met again.

NOTE: In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the transmit buffer full condition. When the transmit buffer is full a data transfer access will trigger a transmit overflow interrupt, if enabled by McBSPi.[MCBSPLP_IRQENABLE_REG\[12\]](#) XOVFLEN bit.

21.5.1.4 Interrupt Configuration

The McBSP module offers two interrupt schemes:

- L4 compliant interrupt request scheme using a common receive/transmit interrupt request line
- The legacy interrupt compliant scheme using 3 interrupt lines: one for receive, one for transmit and the common interrupt line.

21.5.1.4.1 L4-Compliant Interrupt Line

The L4-compliant interrupt line can be configured by using the McBSPi.[MCBSPLP_IRQENABLE_REG](#) register. When the McBSPi.[MCBSPLP_IRQSTATUS_REG](#) bit is set and the corresponding McBSPi.[MCBSPLP_IRQENABLE_REG](#) bit is set to one, the interrupt line is asserted. Writing one to a bit in McBSPi.[MCBSPLP_IRQSTATUS_REG](#) register clears the bit.

There are several conditions, which can be configured to generate an interrupt as follows:

- Transmit buffer empty at end of frame (McBSPi.[MCBSPLP_IRQSTATUS_REG\[14\]](#) XEMPTYEOF bit is set to one when a complete frame was transmitted and the transmit buffer is empty).
- Transmit buffer overflow (McBSPi.[MCBSPLP_IRQSTATUS_REG\[12\]](#) XOVFLSTAT bit is set to one when transmit buffer overflow; the data written while overflow condition is discarded).
- Transmit buffer underflow (McBSPi.[MCBSPLP_IRQSTATUS_REG\[11\]](#) XUNDFLSTAT bit is set to one

- when the transmit data buffer is empty, new data needs to be transmitted).
4. Transmit buffer threshold reached (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[10] XRDY bit is set to one when the transmit buffer free locations are equal or above the [THRSH2_REG + 1] value).
 5. Transmit end of frame (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[9] XEOF is set to one when a complete frame was transmitted).
 6. Transmit frame synchronization (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[8] XFSX bit is set to one when a new transmit frame synchronization is asserted).
 7. Transmit frame synchronization Error (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[7] XSYNCERR is set to one when a transmit frame synchronization error is detected).
 8. Receive buffer overflow (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[5] ROVFLSTAT bit is set to one when receive buffer overflow; the data which is written while overflow condition is discarded).
 9. Receive buffer underflow (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[4] RUNDLSTAT bit is set to one when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined).
 10. Receive buffer threshold Reached (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[3] RRDY bit is set to one when the receive buffer occupied locations are equal or above the [THRSH1_REG + 1] value).
 11. Receive end of frame (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[2] REOF is set to one when a complete frame was received).
 12. Receive frame synchronization (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[1] RFSR bit is set to one when a new receive frame synchronization is asserted).
 13. Receive frame synchronization error (McBSPi.[MCBSPLP_IRQSTATUS_REG](#)[0] RSYNCERR is set to one when a receive frame synchronization error is detected).

21.5.1.4.2 Legacy Interrupt Line

McBSPi_IRQ_TX and McBSPi_IRQ_RX are legacy interrupts. Not to be used for new development. McBSPi_IRQ (common interrupt line) should be preferred.

21.5.1.4.2.1 Set the receive interrupt line (legacy only)

The McBSPi.[MCBSPLP_SPCR1_REG](#)[5:4] RINTM bit field determines which event generates a receive interrupt request, McBSPi_IRQ_RX, to the MPU/IVA2.2 subsystem.

The receive interrupt informs the MPU/IVA2.2 subsystem of changes to the serial port status. Four options exist for configuring this interrupt.

- RINTM=0b00: The receive interrupt generated when the McBSPi.[MCBSPLP_SPCR1_REG](#)[1] RRDY bit changes from 0 to 1. Interrupt on every serial word by tracking the McBSPi.[MCBSPLP_SPCR1_REG](#)[1] RRDY bit. Regardless of the value of RINTM, RRDY bit can be read to detect the RRDY=1 condition.
- RINTM = 0b01: The receive interrupt generated by an end-of-frame condition in the receive multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- RINTM = 0b10: The receive interrupt generated by a new receive frame-synchronization pulse. Interrupt on detection of receive frame-synchronization pulses. This generates an interrupt even when the receiver is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the McBSPi_ICLK clock and sending it to the MPU/IVA2.2 subsystem via the receive interrupt .
- RINTM = 0b11: The receive interrupt generated when McBSPi.[MCBSPLP_SPCR1_REG](#)[3] RSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of RINTM, RSYNCERR can be read to detect this condition. For information on using RSYNCERR, see [Section 21.4.4.3](#).

The McBSP module also provides a common interrupt line McBSPi_IRQ, which can be used by setting the McBSPi.MCBSPLP_IRQENABLE register. All the above settings have equivalent enable bits in the McBSPi.MCBSPLP_IRQENABLE register to enable the common interrupt line:

- RRDYEN is equivalent with RINTM = 0 setting

- REOFEN is equivalent with RINTM = 0b01 setting (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode)
- RFSREN is equivalent with RINTM = 0b10 setting
- RSYNCERREN is equivalent with RINTM = 0b11 setting

This interrupt line has its own status register, McBSPi.[MCBSPLP_IRQSTATUS_REG](#).

21.5.1.4.2.2 Set the transmit interrupt line (legacy only)

The McBSPi.[MCBSPLP_SPCR2_REG](#)[5:4] XINTM bit field determines which event generates a transmit interrupt request (McBSPi_IRQ_TX) to the MPU/IVA2.2 subsystem.

The transmit interrupt informs the MPU/IVA2.2 subsystem of changes to the serial port status. Four options exist for configuring this interrupt.

- XINTM = 0b00: The transmit interrupt generated when the McBSPi.[MCBSPLP_SPCR2_REG](#)[1] XRDY bit changes from 0 to 1. Interrupt on every serial word by tracking the XRDY bit. Regardless of the value of XINTM, XRDY bit can be read to detect the XRDY=1 condition.
- XINTM = 0b01: The transmit interrupt generated by an end-of-frame condition in the transmit multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- XINTM = 0b10: The transmit interrupt generated by a new transmit frame-synchronization pulse. Interrupt on detection of transmit frame-synchronization pulses. This generates an interrupt even when the transmitter is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the McBSPi_ICLK clock and sending it to the MPU/IVA2.2 subsystem via transmit interrupt.
- XINTM = 0b11: The transmit interrupt generated when McBSPi.[MCBSPLP_SPCR2_REG](#)[3] XSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of XINTM, XSYNCERR bit can be read to detect this condition. For information on using XSYNCERR bit, see [Section 21.4.4.6](#).

The McBSP module provides also a common interrupt line McBSPi_IRQ, which can be used by setting the McBSPi.MCBSPLP_IRQENABLE register. All the above settings have equivalent enable bits in the McBSPi.MCBSPLP_IRQENABLE register to enable the common interrupt line:

- XDYEN is equivalent with XINTM = 0b00 setting
- XEOFEN is equivalent with XINTM = 0b01 setting (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode)
- XFSXEN is equivalent with XINTM = 0b10 setting
- XSYNCERREN is equivalent with XINTM = 0b11 setting

This interrupt line has its own status register, McBSPi.[MCBSPLP_IRQSTATUS_REG](#).

21.5.1.5 Receiver Configuration

To configure the McBSP receiver, perform the following procedure:

1. Place the McBSP receiver in reset .
2. Program the McBSP registers for the desired receiver operation.
3. Take the receiver out of reset.

These 3 steps are detailed in the following subsections.

21.5.1.5.1 Resetting (Step 1) and Enabling (Step 3) the Receiver

The first step of the receiver configuration procedure is to reset the receiver, and the last step is to enable the receiver (to take it out of reset).

The serial port can be reset in the following 2 ways:

1. A global reset places the receiver, transmitter, and SRG in reset. When the device reset is removed, McBSPi.MCBSPPLP_SPCR2_REG[6] GRST, McBSPi.MCBSPPLP_SPCR2_REG[7] FRST, McBSPi.MCBSPPLP_SPCR1_REG[0] RRST and McBSPi.MCBSPPLP_SPCR2_REG[0] XRST bits = 0, which keeps the entire serial port in the reset state.
2. The serial port receiver can be reset directly using the McBSPi.MCBSPPLP_SPCR1_REG[0] RRST bit. If the SRG needs to be used, SRG must be reset directly using the McBSPi.MCBSPPLP_SPCR2_REG[6] GRST bit. Similar operations with frame synchronization generator also require using the McBSPi.MCBSPPLP_SPCR2_REG[7] FRST bit when the frame-sync signal must be generated.

To enable the receiver, the preceding bits, cleared to 0, must be set to 1.

21.5.1.5.2 Programming the McBSP Registers for the Desired Receiver Configuration (Step 2)

Figure 21-60 and Figure 21-61 lists important tasks to be performed when the software is configuring the McBSP receiver. Each task corresponds to one or more McBSP register bit fields.

Figure 21-60. Important Tasks to Configure the McBSP Receiver (Part 1)

mcbsp-063

Figure 21-61. Important Tasks to Configure the McBSP Receiver (Part 2)

mcbsp-064

21.5.1.5.2.1 Global Behavior

21.5.1.5.2.1.1 Set the Receiver Pins to Operate as McBSP Pins

The McBSPi.[MCBSPLP_PCR_REG](#)[12] RIOEN bit determines whether the receiver pins are McBSP pins (RIOEN bit=0) or general-purpose I/O pins (RIOEN bit=1).

See [Section 21.5.1.7](#) which describes how to use McBSP pins as GPIO pins.

21.5.1.5.2.1.2 Enable/Disable the Digital Loop Back Mode

The McBSPi.[MCBSPLP_XCCR_REG](#)[5] DLB bit determines whether the digital loopback mode is on or off.

In the digital loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals:

- DR signal is connected on DX signal to receive the transmitted data
- FSR is connected to FRX output signal
- CLKR is connected to the CLKX output signal

This mode allows testing of serial port; the McBSP module receives the data it transmits. This loopback mode is not done through pads, all output signals being disabled.

NOTE: That in digital loopback mode the SRG and the frame synchronization generator need to be enabled to generate the CLKX and FSX signals.

21.5.1.5.2.1.3 Enable/Disable the Analog Loopback Mode

The McBSPi.[MCBSPLP_SPCR1_REG](#)[15] ALB bit determines whether the analog loopback mode is on or off.

In the analog loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit loop back signals:

- DR is connected to transmit loop back data on DX input pin
- FSR is connected to FRX input pin
- CLKR is connected to the CLKX input pin

This Analog Loopback mode is also done to test the Input/Output buffers, through pads.

21.5.1.5.2.1.4 Enable/disable the synchronous transmit-receive mode (McBSP1 only)

The control registers of the System Control Module is used to configure the synchronous transmit-receive mode.

The MCBSP1_CLKR bit of the CONTROL_DEVCONF0[3] register is used to select the McBSP1 module CLKR signal source:

- When set to '0', the CLKR source is from the CLKR input signal
- When set to '1', the CLKR source is from the CLKX input signal

The MCBSP1_FSR bit of the CONTROL_DEVCONF0[4] register is used to select the McBSP1 module FSR signal source:

- When set to '0', the FSR source is from the FSR input signal
- When set to '1', the FSR source is from the FSX input signal

21.5.1.5.2.1.5 Enable/Disable the Receive Multichannel Selection Mode

The McBSPi.[MCBSPLP_MCR1_REG](#)[0] RMCM bit determines whether the receive multichannel selection mode is on or off.

For further details, see [Section 21.4.6.5](#).

21.5.1.5.2.2 Data Behavior

21.5.1.5.2.2.1 Choose 1 or 2 Phases for the Receive Frame

The McBSPi.[MCBSPLP_RCR2_REG](#)[15] RPHASE bit determines whether the receive data frame has one (Single phase) or two phases (Dual phase). When dual-phase is selected the number of words per phase must be set to one.

21.5.1.5.2.2.2 Set the Receive Word Length(s)

The McBSPi.[MCBSPLP_RCR1_REG](#)[7:5] RWDLEN1 and McBSPi.[MCBSPLP_RCR2_REG](#)[7:5] RWDLEN2 bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the receive data frame.

If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame.

If a dual-phase frame is selected, RWDLEN1 and RWDLEN2 must be set to select the both length. These both bits can have values different.

21.5.1.5.2.2.3 Set the Receive Frame Length

The receive frame length is the number of serial words in the receive frame.

The McBSPi.[MCBSPLP_RCR1_REG\[14:8\]](#) RFRLEN1 and McBSPi.[MCBSPLP_RCR2_REG\[14:8\]](#) RFRLEN2 bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the receive data frame.

If a dual-phase frame is selected (RPHASE=1), the frame length must be two words (one word for phase 1 plus the one word for phase 2). Others values must not be used.

The 7-bit RFRLEN1 field allows up to 128 words per phase when single-phase frame. See [Table 21-26](#) below for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the RFRLEN fields with [W - 1], where W represents the number of words per phase. For example, to get a phase length of 128 words in phase 1, load 127 words into RFRLEN1.

Table 21-26. How to Calculate the Length of the Receive Frame

RPHASE	RFRLEN1	RFRLEN2	Frame Length
0	0 ≤ RFRLEN1 ≤ 127	Don't care	(RFRLEN1 value +1) words
1	RFRLEN1 = 0	RFRLEN2 = 0	2 words

21.5.1.5.2.2.4 Set the Receive Reverse Mode

The McBSPi.[MCBSPLP_RCR2_REG\[4:3\]](#) RREVERSE bit field determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

For further information about reverse mode, see [Section 21.4.2.2](#).

21.5.1.5.2.2.5 Set the Receive Data Delay

The McBSPi.[MCBSPLP_RCR2_REG\[1:0\]](#) RDATDLY bit field determines the length of the data delay for the receive frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

McBSPi.[MCBSPLP_RCR2_REG\[1:0\]](#) RDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks (RDATDLY = 0b00–0b10), as shown in [Figure 21-62](#) below. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

Figure 21-62. Range of Programmable Data Delay

21.5.1.5.2.2.5.1 0-Bit Data Delay

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR, and thus on mcbsp_dx. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the mcbsp_dx pin.

21.5.1.5.2.2.5.2 2-Bit Data Delay

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in [Figure 21-63](#). In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

Figure 21-63. 2-Bit Data Delay Used to Skip a Framing Bit

mcbsp-053

21.5.1.5.2.2.6 Set the Receive Sign-Extension and Justification Mode

The McBSPi.[MCBSPLP_SPCR1_REG](#)[14:13] RJUST bit field determines whether data received by the McBSP module is sign-extended or not and how it is justified.

RJUST bit selects whether data in RB is right- or left-justified (with respect to the MSB) in McBSPi.[MCBSPLP_DRR_REG](#) register and whether unused bits in McBSPi.[MCBSPLP_DRR_REG](#) are filled with zeroes or with sign bits.

[Table 21-27](#) and [Table 21-28](#) show the effects of various RJUST values; the effect on an example 12-bit receive-data value 0xABC, and the effect on an example 20-bit receive-data value 0ABCDE, respectively.

Table 21-27. Example: Use of RJUST Bit Field With 12-bit Data Value 0xABC

RJUST	Justification	Extension	Value in DRR_REG
0b00	Right	Zero fill MSBs	0x0000 0ABC
0b01	Right	Sign extend data into MSBs	0xFFFF FABC
0b10	Left	Zero fill LSBs	0xABCO 0000
0b11	Reserved	Reserved	Reserved

Table 21-28. Example: Use of RJUST Bit Field With 20-bit Data Value 0xABCD E000

RJUST	Justification	Extension	Value in DRR_REG
0b00	Right	Zero fill MSBs	0x000A BCDE
0b01	Right	Sign extend data into MSBs	0xFFFF BCDE
0b10	Left	Zero fill LSBs	0xABCD E000

Table 21-28. Example: Use of RJUST Bit Field With 20-bit Data Value 0xABCD (continued)

RJUST	Justification	Extension	Value in DRR_REG
0b11	Reserved	Reserved	Reserved

21.5.1.5.2.2.7 Set the Receive Interrupt Mode

Please refer to [Section 21.5.1.4.2.1](#).

21.5.1.5.2.2.8 Set the Receive DMA Mode

The McBSP receive-data DMA requests (McBSPi_DMA_RX) are active after the McBSPi.[MCBSPLP_SPCR1_REG](#) [0] RRST bit is released. After reset, the default DMA threshold (and length) is 1.

The receive DMA requests can be disabled by setting the McBSPi.[MCBSPLP_RCCR_REG](#)[3] RDMAEN bit to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending, and the DMA state-machine is not reset.

To configure the McBSP receive data DMA requests, perform the following:

- Write the receive McBSPi.[MCBSPLP_THRSH1_REG](#) register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1).
- As long as the occupied locations level in the RB is above or equal to the THRSH1_REG value + 1, the DMA request is asserted.
- After transferring the configured (THRSH1_REG value + 1) number of words, the receive DMA request is deasserted, and then reasserted as soon as the conditions are met again.

21.5.1.5.2.3 Frame-Sync Behavior

21.5.1.5.2.3.1 Set the Receive Frame-Sync Mode

McBSPi.[MCBSPLP_PCR_REG](#)[10] FSRM bit, McBSPi.[MCBSPLP_SRGR2_REG](#)[15] GSYNC bit, McBSPi.[MCBSPLP_SPCR1_REG](#)[15] ALB bit and McBSPi.[MCBSPLP_XCCR_REG](#)[5] DLB bit field are used to determine the source for receive frame synchronization and the function of the mcbsp_fsr pin.

[Table 21-29](#) below shows how you can select various sources to provide the receive frame-synchronization signal and the effect on the mcbsp_fsr pin. The polarity of the signal on the mcbsp_fsr pin is determined by the McBSPi.[MCBSPLP_PCR_REG](#)[2] FSRP bit.

Table 21-29. FSRM and GSYNC Effects on Frame-Sync Signal and mcbsp_fsr Pin

FSRM	GSYNC	Source of Receive Frame Synchronization	MCBSPLP.FSR Pin Status
0	0 or 1	An external frame synchronization signal enters the McBSP module through the mcbsp_fsr pin. The signal is then inverted as determined by FSRP bit before being used as internal FSR.	Input
1	0	Internal FSR is driven by the SRG frame-synchronization signal (FSG).	Output. FSG is inverted as determined by FSRP bit before being driven out on the mcbsp_fsr pin.
1	1	Internal FSR is driven by the SRG frame-synchronization signal (FSG).	Input. The external frame-synchronization input on the mcbsp_fsr pin is used to synchronize CLKG and generate FSG pulses.

In digital loop-back mode (DLB=1), the transmit frame-synchronization signal is used as the receive frame-synchronization signal.

Also in the analog loop back mode (ALB=1), the internal receive clock signal (CLKR), and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

For more details on clock and frame-sync configuration, see [Section 21.4.3](#).

21.5.1.5.2.3.2 Set the Receive Frame-Sync Polarity

The McBSPi.[MCBSPLP_PCR_REG](#)[2] FSRP bit determines whether frame-synchronization pulses are active high or active low on the mcbsp_fsr pin.

Receive frame-synchronization pulses can be generated internally by the SRG or driven by an external source. The source of frame synchronization is selected by programming the McBSPi.[MCBSPLP_PCR_REG](#)[10] FSRM bit. FSR is also affected by the McBSPi.[MCBSPLP_SRGR2_REG](#)[15] GSYNC bit. For information about the effects of FSRM and GSYNC, see [Section 21.5.1.5.2.3.1, Set the Receive Frame-Sync Mode](#).

When FSR and FSX are inputs (FSXM = FSRM = 0, external frame-synchronization pulses), the McBSP module detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the mcbspi_dr pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from an external source via CLK(R/X) pins or driven by the SRG clock (CLKG) internal to the McBSP module.

When FSR and FSX are outputs, implying that they are driven by the SRG, they are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X). Similarly, data on the mcbsp_dx pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP bit fields in the pin control register (McBSPi.[MCBSPLP_PCR_REG](#)) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

[Figure 21-64](#) shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

Figure 21-64. Data Externally Clocked on a Rising Edge and Sampled on a Falling Edge

mcbsp-054

21.5.1.5.2.3.3 Set the SRG Frame-Sync Period and Pulse Width

The SRG can produce a clock signal, CLKG, and FSG. If the SRG is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

McBSPi.[MCBSPLP_SRGR2_REG](#)[11:0] FPER bit field is used to set the SRG frame-sync period and McBSPi.[MCBSPLP_SRGR1_REG](#)[15:8] FWID bit field is used to set the SRG pulse width.

On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is (FPER+1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC=1, FPER is a don't care value.

Each pulse on FSG has a width of (FWID+1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0.

Figure 21-65 shows a frame-synchronization period of 16 CLKG periods (FPER=15 or 00001111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID=1).

Figure 21-65. Frame of Period 16 CLKG Periods and Active Width of 2 CLKG Periods

When the SRG comes out of reset, FSG is in its inactive state. Then, when GRST=1 and FSGM=1, a frame-synchronization pulse is generated. The frame width value (FWID+1) is counted down on every CLKG cycle until it reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER+1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

21.5.1.5.2.4 Clock Behavior

21.5.1.5.2.4.1 Set the receive clock mode

McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit, McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit and McBSPi.MCBSPLP_XCCR_REG[5] DLB bit are used to set the receive clock mode.

Table 21-30 shows how to select various sources to provide the receive clock signal and affect the mcbsp_clk pin. The McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit determines the polarity of the signal on the mcbsp_clk pin.

Table 21-30. CLKRM Effect on Receive Clock Signal and mcbsp_clk Pin

CLKRM	Source of Receive Clock	mcbsp_clk Pin Status
0	The mcbsp_clk pin is an input driven by an external clock. The external clock signal is inverted as determined by CLKRP bit before being used.	Input
1	The SRG clock (CLKG) drives internal CLKR.	Output. CLKG, inverted as determined by CLKRP, is driven out on the mcbsp_clk pin.

In the digital loop-back mode (DLB = 1) or analog loop-back mode (ALB = 1), the transmit clock signal is used as the receive clock signal. For more details on clock configuration, see [Section 21.4.3.1](#).

21.5.1.5.2.4.2 Set the Receive Clock Polarity

McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit is used to set the receive clock polarity.

The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the mcbsp_clk pin.

NOTE: CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

21.5.1.5.2.4.3 Set the SRG Clock Divide-Down Value

McBSPi.[MCBSPLP_SRGR1_REG](#)[7:0] CLKGDV bit field is used to set the SRG clock divide-down value.

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to $1/(CLKGDV + 1)$ of SRG input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. The CLKG duty cycle is 50 percent.

21.5.1.5.2.4.4 Set the SRG Clock Synchronization Mode

McBSPi.[MCBSPLP_SRGR2_REG](#)[15] GSYNC bit is used to set the SRG clock synchronization mode.

For more information about the clock synchronization feature, see [Section 21.4.3](#).

21.5.1.5.2.4.5 Set the SRG Clock Mode (Choose an Input Clock)

McBSPi.[MCBSPLP_PCR_REG](#)[7] SCLKME bit and McBSPi.[MCBSPLP_SRGR2_REG](#)[13] CLKSM bit are used to set the SRG clock mode.

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock.

For further details about the clock synchronization feature, see [Section 21.4.3](#).

21.5.1.5.2.4.6 Set the SRG Input Clock Polarity

McBSPi.[MCBSPLP_SRGR2_REG](#)[14] CLKSP bit, McBSPi.[MCBSPLP_PCR_REG](#)[1] CLKXP bit and McBSPi.[MCBSPLP_PCR_REG](#)[0] CLKRP bit are used to set the SRG input clock polarity.

The SRG can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the SRG must be driven by an input clock signal derived from the McBSP_FCLK clock or from an external clock on the mcbsp_clks, mcbsp_clkx, or mcbsp_clkr pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKSP for the mcbsp_clks pin, CLKXP for the mcbsp_clkx pin, CLKRP for the mcbsp_clkr pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

21.5.1.6 Transmitter Configuration

To configure the McBSP transmitter, perform the following procedure:

1. Place the McBSP transmitter in reset
2. Program the McBSP registers for the desired transmitter operation
3. Take the transmitter out of reset

These 3 steps are described in more details in the sub-sections below.

21.5.1.6.1 Resetting (Step 1) and Enabling (Step 3) the Transmitter

The first step of the transmitter configuration procedure is to reset the transmitter, and the last step is to enable the transmitter (to take it out of reset).

The serial port can be reset in the following two ways:

1. A global reset places the receiver, transmitter, and SRG in reset. When the device reset is removed, McBSPi.[MCBSPLP_SPCR2_REG](#)[6] GRST, McBSPi.[MCBSPLP_SPCR2_REG](#)[7] FRST, McBSPi.[MCBSPLP_SPCR1_REG](#)[0] RRST and McBSPi.[MCBSPLP_SPCR2_REG](#)[0] XRST bits = 0, which keeps the entire serial port in the reset state.

2. The serial port receiver can be reset directly using the McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit. If the SRG needs to be used, SRG must be reset directly using the McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit. Similar operation with the Frame Synchronization Generator also requires using the McBSPi.MCBSPLP_SPCR2_REG[7] FRST bit when the frame-sync signal must be generated.

To enable the transmitter, the preceding bits, cleared to 0, must be set to 1.

21.5.1.6.2 Programming the McBSP Registers for the Desired Transmitter Operation (Step 2)

Figure 21-66 and Figure 21-67 list important tasks to be performed when configuring the McBSP transmitter. Each task corresponds to one or more McBSP register bit fields.

Figure 21-66. Important Tasks to Configure the McBSP Transmitter (Part 1)

mcbsp-065

Figure 21-67. Important Tasks to Configure the McBSP Transmitter (Part 2)

mcbsp-066

21.5.1.6.2.1 Global Behavior

21.5.1.6.2.1.1 Set the Transmitter Pins to Operate as McBSP Pins

McBSPi.[MCBSPLP_PCR_REG](#)[13] XIOEN bit determines whether the transmitter pins are McBSP pins (XIOEN=0) or general-purpose I/O pins (XIOEN=1).

See [Section 21.5.1.7](#) which describes how to use McBSP pins as GPIO pins.

21.5.1.6.2.1.2 Enable/Disable the Digital Loop-Back Mode

See [Section 21.5.1.5.2.1.2](#).

21.5.1.6.2.1.3 Enable/Disable the Analog Loop-Back Mode

See [Section 21.5.1.5.2.1.3](#).

21.5.1.6.2.1.4 Enable/Disable the Synchronous Transmit-Receive Mode (McBSP1 only)

See [Section 21.5.1.5.2.1.4](#).

21.5.1.6.2.1.5 Enable/Disable the Transmit Multichannel Selection

McBSPi.[MCBSPLP_MCR2_REG](#)[1:0] XMCM bit field determines whether the transmit multichannel selection mode is on or off.

See [Section 21.4.6.7](#).

21.5.1.6.2.2 Data Behavior

21.5.1.6.2.2.1 Choose 1 or 2 Phases for the Transmit Frame

McBSPi.[MCBSPLP_XCR2_REG\[15\]](#) XPHASE bit determines whether the transmit data frame has one (Single phase) or two phases (Dual phase). When dual-phase is selected the number of words per phase must be set to one.

21.5.1.6.2.2.2 Set the Transmit Word Length(s)

McBSPi.[MCBSPLP_XCR1_REG\[7:5\]](#) XWDLEN1 and McBSPi.[MCBSPLP_XCR2_REG\[7:5\]](#) XWDLEN2 bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the transmit data frame.

If a single-phase frame is selected, XWDLEN1 selects the length for every serial word received in the frame.

If a dual-phase frame is selected, XWDLEN1 and XWDLEN2 must be set to select the both length. These both bits can have values different.

21.5.1.6.2.2.3 Set the Transmit Frame Length

The transmit frame length is the number of serial words in the transmit frame.

McBSPi.[MCBSPLP_XCR1_REG\[14:8\]](#) XFRLEN1 and McBSPi.[MCBSPLP_XCR2_REG\[14:8\]](#) XFRLEN2 bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the transmit data frame.

If a dual-phase frame is selected (XPHASE=1), the frame length is 2 words, the length of phase 1 (one word) plus the length of phase 2 (one word). Others values must not be used.

The 7-bit XFRLEN fields allow up to 128 words per phase. See [Table 21-31](#) for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the XFRLEN fields with [W minus 1], where W represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1.

Table 21-31. How to Calculate the Length of the Transmit Frame

XPHASE	XFRLEN1	XFRLEN2	Frame Length
0	$0 \leq XFRLEN1 \leq 127$	Don't care	(XFRLEN1 value +1) words
1	$XFRLEN1 = 0$	$XFRLEN2 = 0$	2 words

21.5.1.6.2.2.4 Set the Transmit Reverse Mode

McBSPi.[MCBSPLP_XCR2_REG\[4:3\]](#) XREVERSE bit field determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

For additional information about reverse mode, see [Section 21.4.2.2](#).

21.5.1.6.2.2.5 Set the Transmit Data Delay

McBSPi.[MCBSPLP_XCR2_REG\[1:0\]](#) XDATDLY bit field determines the length of the data delay for the transmit frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

XDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks (XDATDLY=00b–10b), as shown in [Figure 21-68](#). In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

NOTE: Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

Figure 21-68. Range of Programmable Data Delay

21.5.1.6.2.2.5.1 0-Bit Data Delay:

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on mcbspi_dx. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the mcbspi_dx pin.

21.5.1.6.2.2.5.2 2-Bit Data Delay:

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in [Figure 21-69](#). The data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

Figure 21-69. 2-Bit Data Delay Used to Skip a Framing Bit

21.5.1.6.2.2.6 Set the Transmit DXENA Mode

McBSPi.[MCBSPLP_SPCR1_REG\[7\]](#) DXENA bit is used to set the transmit DXENA (DX delay enable) mode.

The DXENA bit controls the delay enabler on the mcbsp_dx pin. Set DXENA to enable an extra delay for turn-on time. This bit does not control the data itself, so only the first bit is delayed (the delay is given by a combinatorial delay buffer). The inserted delay: 13 ns, 18 ns (default), 24 ns, or 30 ns can be set using the McBSPi.[MCBSPLP_XCCR_REG\[13:12\]](#) DXENDLY bit field. If you tie together the mcbsp_dx pins of multiple McBSP modules, make sure DXENA = 1, to avoid having more than one McBSP transmitting on the data line at one time.

21.5.1.6.2.2.7 Set the Transmit Interrupt Mode

See [Section 21.5.1.4.2.2](#).

21.5.1.6.2.2.8 Set the Transmit DMA Mode

The McBSP transmit data DMA requests (McBSPi_DMA_TX) are active after the transmit McBSPi.[MCBSPLP_SPCR2_REG\[0\]](#) XRST bit is released. After reset, the default DMA threshold (and length) is 1.

The transmit DMA requests can be disabled by setting the McBSPi.[MCBSPLP_XCCR_REG\[3\]](#) XDMAEN bit to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending, and the DMA state-machine is not reset.

To configure the McBSP transmit data DMA requests, follow this procedure:

- Write the transmit McBSPi.[MCBSPLP_THRSH2_REG](#) register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1).
- As long as the free locations level in XB is above or equal to the THRSH2_REG value + 1, the DMA request is asserted.
- After transferring the configured (THRSH2_REG value + 1) number of words, the transmit DMA request is deasserted, and then reasserted as soon as the conditions are met again.

21.5.1.6.2.3 Frame-Synchronization Behavior

21.5.1.6.2.3.1 Set the Transmit Frame-Sync Mode

McBSPi.[MCBSPLP_PCR_REG\[11\]](#) FSXM bit and McBSPi.[MCBSPLP_SRGR2_REG\[12\]](#) FSGM bit are used to set the transmit frame-sync mode.

[Table 21-32](#) shows how FSXM and FSGM select the source of transmit frame-synchronization pulses. The three choices are:

1. External frame-synchronization input
2. Sample rate generator frame-synchronization signal (FSG)
3. Sample rate generator frame-synchronization signal (FSG) gated by the transmit buffer XB empty condition.

[Table 21-32](#) also shows the effect of each bit setting on the mcbsp_fsx pin. The FSXP bit determines the polarity of the signal on the mcbsp_fsx pin.

Table 21-32. How FSXM and FSGM Select the Source of Transmit Frame-Sync Pulses

FSXM	FSGM	Source of Transmit Frame Synchronization	mcbsp_fsx Pin Status
0	0 or 1	An external FSG enters the McBSP through the mcbsp_fsx pin. The signal is then inverted by FSXP bit before being used as internal FSX.	Input
1	1	Internal FSX is driven by the SRG FSG.	Output. FSG is inverted by FSXP bit before being driven out on mcbsp_fsx pin.
1	0	A XB empty condition causes the McBSP not to generate a transmit frame-synchronization pulse. The frame synchronization is generated taking into account the FWID and FPER bits as long as the transmit buffer is not empty. When the buffer is empty the generated frame synchronization signal is gated.	Output. The generated frame-synchronization pulse is inverted as determined by FSXP bit before being driven out on mcbsp_fsx pin.

If the SRG creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the mcbsp_fsr pin. For more details, see [Section 21.4.3.3](#).

In the digital loopback mode (DLB=1) or analog loopback mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal. For more details on frame-sync configuration, see [Section 21.4.3.2](#).

21.5.1.6.2.3.2 Set the Transmit Frame-Sync Polarity

McBSPi.[MCBSPLP_PCR_REG](#)[3] FSXP bit determines whether frame-synchronization pulses are active high or active low on the mcbsp_fx pin.

Transmit frame-synchronization pulses can be generated internally by the SRG or driven by an external source. The source of frame synchronization is selected by programming the McBSPi.[MCBSPLP_PCR_REG](#)[11] FSXM bit. FSX is also affected by the McBSPi.[MCBSPLP_SRGR2_REG](#)[12] FSGM bit. For information about the effects of FSXM and FSGM, see [Section 21.5.1.6.2.3.1](#).

When FSR and FSX are inputs (FSXM=FSRM=0, external frame-synchronization pulses), the McBSP module detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the mcbsp_dr pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the SRG clock (CLKG) internal to the McBSP module.

When FSR and FSX are outputs, implying that they are driven by the SRG, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the mcbsp_dx pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All FSG (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP=FSXP=1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC=0) is selected and the polarity bit FS(R/X)P=1, the internal active-high FSG are inverted before being sent to the FS(R/X) pin.

21.5.1.6.2.3.3 Set the SRG Frame-Sync Period and Pulse Width

See [Section 21.5.1.5.2.3.3](#).

21.5.1.6.2.4 Clock Behavior

21.5.1.6.2.4.1 Set the Transmit Clock Mode

The McBSPi.[MCBSPLP_PCR_REG](#)[9] CLKXM bit is used to set the transmit clock mode.

[Table 21-33](#) shows how the CLKXM bit selects the transmit clock and the corresponding status of the mcbsp_clkx pin. The CLKXP bit determines the polarity of the signal on the mcbsp_clkx pin.

Table 21-33. CLKXM Bit Effect on Transmit Clock and MCBSPLP.CLKX Pin

CLKXM	Source of Transmit Clock	mcbsp_clkx Pin Status
0	Internal CLKX is driven by an external clock on the mcbsp_clkx pin. CLKX is inverted as determined by CLKXP before being used.	Input
1	Internal CLKX is driven by the SRG clock, CLKG.	Output. CLKG, inverted as determined by CLKXP, is driven out on mcbsp_clkx.

If the SRG creates a clock signal (CLKG) that is derived from an external input clock, the GSYNC bit determines whether CLKG is kept synchronized with pulses on the mcbsp_fsr pin.

In the digital loopback mode (DLB=1) or analog loopback mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal. For more details on clock configuration, see [Section 21.4.3.1](#).

21.5.1.6.2.4.2 Set the Transmit Clock Polarity

The McBSPi.[MCBSPLP_PCR_REG](#)[1] CLKXP bit is used to set the transmit clock polarity.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP=1 and external clocking is selected (CLKXM=0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP=1 and internal clocking is selected (CLKXM=1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the mcbsp_clkx pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP=1 and external clocking is selected (CLKRM=0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP=1 and internal clocking is selected (CLKRM=1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the mcbsp_clkr pin.

NOTE: CLKRP=CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

21.5.1.6.2.4.3 Set the SRG Clock Divide-Down Value

See [Section 21.5.1.5.2.4.3](#).

21.5.1.6.2.4.4 Set the SRG Clock Synchronization Mode

See [Section 21.5.1.5.2.4.4](#).

21.5.1.6.2.4.5 Set the SRG Clock Mode (Choose an Input Clock)

See [Section 21.5.1.5.2.4.5](#).

21.5.1.6.2.4.6 Set the SRG Input Clock Polarity

See [Section 21.5.1.5.2.4.6](#).

21.5.1.7 General-Purpose I/O on the McBSP Pins (Legacy Only)

[Table 21-34](#) summarizes how to use the McBSP pins as general-purpose I/O pins. All the bits mentioned in the table except XRST and RRST bits are in the pin control register (McBSPi.[MCBSPLP_PCR_REG](#)). McBSPi.[MCBSPLP_SPCR2_REG](#)[0] XRST bit and McBSPi.[MCBSPLP_SPCR1_REG](#)[0] RRST bit are in the serial port control registers.

To use receiver pins mcbsp_clkr, mcbsp_fsr, and mcbsp_dr as general-purpose I/O pins rather than as serial port pins, you must set two conditions:

1. The receiver of the serial port is in reset (McBSPi.[MCBSPLP_SPCR1_REG](#)[0] RRST bit =0).
2. General-purpose I/O is enabled for the serial port receiver (McBSPi.[MCBSPLP_PCR_REG](#)[12] RIOEN=1).

The mcbsp_clk and mcbsp_fsr pins can be individually configured as either input or output pins with the CLKRM and FSRM bits, respectively. The mcbsp_dr pin can only be an input pin. [Table 21-34](#) shows, which bits in McBSPi.[MCBSPLP_PCR_REG](#) are used to read from/write to these pins.

For the transmitter pins mcbsp_clkx, mcbsp_fsx, and mcbsp_dx, you must meet two conditions:

1. The transmitter of the serial port is in reset (McBSPi.[MCBSPLP_SPCR2_REG](#)[0] XRST=0).
2. General-purpose I/O is enabled for the serial port transmitter (McBSPi.[MCBSPLP_PCR_REG](#)[12] XIOEN=1).

The mcbsp_clkx and mcbsp_fsx pins can be individually configured as input or output pins with the CLKXM and FSXM bits, respectively. The mcbsp_dx pin can only be an output pin. [Table 21-34](#) shows the bits in McBSPi.[MCBSPLP_PCR_REG](#) used to read from/write to these pins.

For the mcbsp_clks pin (common to all McBSP modules), all of the reset and I/O enable conditions must be met:

1. Both the receiver and transmitter of the serial port are in reset (RRST=0 and XRST=0).
2. General-purpose I/O is enabled for both the receiver and the transmitter (RIOEN=1 and XIOEN=1).

The mcbsp_clks pin can only be an input pin. To read the status of the signal on the mcbsp_clks pin, read the McBSPi.[MCBSPLP_PCR_REG](#)[6] CLKS_STAT bit.

Table 21-34. Using McBSP Pins for General-Purpose I/O

Pin	General-Purpose use enabled by this bit combination	Selected as output when	Output value driven from this bit	Selected as input when	Input value read from this bit
mcbsp_clkx	XRST = 0 XIOEN = 1	CLKXM = 1	CLKXP	CLKXM = 0	CLKXP
mcbsp_fsx	XRST = 0 XIOEN = 1	FSXM = 1	FSXP	FSXM = 0	FSXP
mcbsp_dx	XRST = 0 XIOEN = 1	Always	DX_STAT	Never	Does not apply
mcbsp_clk	RRST = 0 RIOEN = 1	CLKRM = 1	CLKRP	CLKRM = 0	CLKRP
mcbsp_fsr	RRST = 0 RIOEN = 1	FSRM = 1	FSRP	FSRM = 0	FSRP
mcbsp_dr	RRST = 0 RIOEN = 1	Never	Does not apply	Always	DR_STAT
mcbsp_clks	RRST = XRST = 0 RIOEN = XIOEN = 1	Never	Does not apply	Always	CLKS_STAT

21.5.1.8 Data Packing Examples

This section describes two ways to implement data packing in the McBSP: Using frame length and word length, and using word length and ignoring frame sync pulses.

21.5.1.8.1 Data Packing Using Frame Length and Word Length

Frame length and word length can be manipulated to pack data effectively. For example, four 8-bit words are transferred in a single-phase frame, as shown in [Figure 21-70](#). In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 00011b: 4-word frame
- (R/X)WDLEN1 = 101b: 32-bit words

Four 8-bit data words are transferred to and from the McBSP by the MPU/IVA2.2 subsystems or the sDMA controller. Thus, four reads from McBSPi.[MCBSPLP_DRR_REG](#) and four writes to McBSPi.[MCBSPLP_DXR_REG](#) are necessary for each frame.

Figure 21-70. Four 8-bit Data Words Transferred To/From McBSP Module

mcbsp-058

This data can also be treated as a single-phase frame consisting of one 32-bit data word, as shown in [Figure 21-71](#). In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 0000000b: 1-word frame
- (R/X)WDLEN1 = 000b: 8-bit words

Two 16-bit data words are transferred to and from the McBSP by the MPU/IVA2.2 subsystems or the sDMA controller. Thus, two reads from McBSPi.[MCBSPLP_DRR_REG](#) and two writes to McBSPi.[MCBSPLP_DXR_REG](#) are necessary for each frame. This results in only half the number of transfers, as compared to the previous case. This manipulation reduces the percentage of bus time required for serial port data movement.

Figure 21-71. One 32-bit Data Word Transferred To/From McBSP Module

mcbsp-059

21.5.1.8.2 Data Packing Using Word Length and the Frame-Sync Ignore Function

When there are multiple words per frame, data can be packed by increasing the word length (defining a serial word with more bits) and by ignoring frame-sync pulses. [Figure 21-72](#) shows the McBSP operating at the maximum packet frequency. Here, each frame has only one 8-bit word. Notice the frame-sync pulse that initiates each frame transfer for reception and for transmission. For reception, this configuration requires one read operation for each word. For transmission, this configuration requires one write operation for each word.

Figure 21-72. 8-bit Data Words Transferred at Maximum Packet Frequency

mcbsp-060

Figure 21-73 shows the McBSP configured to treat this data stream as a continuous 32-bit word. In this example, the McBSP responds to an initial frame-sync pulse. However, the McBSP ignores subsequent pulses. Only one read transfer or one write transfer is required every 32 bits. This configuration effectively reduces the required bus bandwidth to one-fourth the bandwidth needed to transfer four 8-bit words.

Figure 21-73. Configuring the Data Stream as a Continuous 32-bit Word

mcbsp-061

21.5.2 SIDETONE Feature

21.5.2.1 SIDETONE Activation Procedure

Before you enable a SIDETONE selection mode, make sure you properly configure the data frame for multichannel mode of the McBSP module:

- Select a single-phase frame (McBSPi.[MCBSPLP_RCR2_REG](#)[15] RPHASE bit and McBSPi.[MCBSPLP_XCR2_REG](#)[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set to 1 the McBSPi.[MCBSPLP_MCR1_REG](#)[0] RMCM bit, to select multichannel mode enable.
- Set a frame length (McBSPi.[MCBSPLP_RCR1_REG](#)[14:8] RFRLEN1 bit field and McBSPi.[MCBSPLP_XCR1_REG](#)[14:8] XFRLEN1 bit field) that includes the highest-numbered channel to be used (a maximum of 4 channels can be used in this configuration).
- Set a word length (McBSPi.[MCBSPLP_RCR1_REG](#)[7:5] RWDLEN1 bit field and McBSPi.[MCBSPLP_XCR1_REG](#)[7:5] XWDLEN1 bit field) to be either 16, 24 or 32 (see the note)

below).

- Select the input/output channels configured as SIDETONE channels by setting the following bit fields listed in [Table 21-35](#):

Table 21-35. Selection of the SIDETONE Input and Output Channels

Bit field	Description
McBSPi. MCBSPLP_SSELCR_REG [9:7] OCH1ASSIGN	Map the CH1 data for the speaker out channels to one of the McBSP channels (1 out of 8 channels)
McBSPi. MCBSPLP_SSELCR_REG [6:4] OCH0ASSIGN	Map the CH0 data for the speaker out channels to one of the McBSP channels (1 out of 8 channels)
McBSPi. MCBSPLP_SSELCR_REG [3:2] ICH1ASSIGN	Map the CH1 data from the digital microphone channels to one of the McBSP channels (1 out of 4 channels)
McBSPi. MCBSPLP_SSELCR_REG [1:0] ICH0ASSIGN	Map the CH0 data from the digital microphone channels to one of the McBSP channels (1 out of 4 channels)

- Enable SIDETONE by setting 2 bits to 1:
 1. In McBSP module, the McBSPi.[MCBSPLP_SSELCR_REG](#)[10] SIDETONEEN bit
 2. In SIDETONE core, the McBSPi.[ST_SSELCR_REG](#)[0] SIDETONEEN bit

NOTE: Word width in the loop is 24 bits. If input channel word width is less than 24 bits, LSBs of the samples are zero padded. If input channel word width is more than 24 bits, samples are truncated.

21.5.2.2 SIDETONE Initialization Procedure

The SIDETONE core initialization procedure is as follows:

1. Write 1 in McBSPi.[ST_SSELCR_REG](#)[1] COEFFWREN bit to enable loading of the FIR coefficients.
2. Load one by one the FIR coefficients performing 128 write accesses to McBSPi.[ST_SFIRCR_REG](#)[15:0] FIRCOEFF bit field, the McBSPi.[ST_SFIRCR_REG](#)[0] FIRCOEFF bit is loaded first. To ensure the completion of loading, check the status bit-field, McBSPi.[ST_SSELCR_REG](#)[2] COEFFWRDONE bit.
3. Set-up gain values for both channels writing desired values inside McBSPi.[ST_SGAINCR_REG](#)[31:16] CH1GAIN bit field for the second sidetone channel and McBSPi.[ST_SGAINCR_REG](#)[15:0] CH0GAIN bit field for the first sidetone channel.

21.5.2.3 SIDETONE FIR Coefficients Writing

Writing the coefficients is only possible when the SIDETONE is disabled.

1. Write 1 in McBSPi.[ST_SSELCR_REG](#)[1] COEFFWREN bit to enable writing of the FIR coefficients, or write 0, and then write 1 in the COEFFWREN bit to reset the write process.
2. Perform 128 write accesses in 32/16 LSB bit mode on the McBSPi.[ST_SFIRCR_REG](#)[15:0] FIRCOEFF bit field. The first write action following the previous step sets the coefficient index 0.
3. Check that the write is done by reading McBSPi.[ST_SSELCR_REG](#)[2] COEFFWRDONE bit (it becomes 1 after the 128th coefficient is written).

21.5.2.4 SIDETONE FIR Coefficients Reading

Reading the coefficients is only possible when the SIDETONE is disabled.

- Write 0 in McBSPi.[ST_SSELCR_REG](#)[1] COEFFWREN bit to enable reading of the FIR coefficients, or write 1, and then write 0 in the COEFFWREN bit to reset the read process.
- Perform 128 read accesses from McBSPi.[ST_SFIRCR_REG](#)[15:0] FIRCOEFF bit field. Each read returns coefficients one by one. The first read following previous step returns coefficient index 0.

21.6 McBSP Register Manual

[Table 21-36](#) shows the base address and address space for the McBSP module instances.

Table 21-36. McBSP Instance Summary

Module Name	Base Address (hex)	Size
McBSP1	0x4807 4000	4K bytes
McBSP5	0x4809 6000	4K bytes
McBSP2	0x4902 2000	4K bytes
McBSP3	0x4902 4000	4K bytes
McBSP4	0x4902 6000	4K bytes
SIDETONE_McBSP2	0x4902 8000	4K bytes
SIDETONE_McBSP3	0x4902 A000	4K bytes

21.6.1 McBSP Register Mapping Summary

CAUTION

The McBSP data registers (that is, DXR_REG for data transmit and DRR_REG for data receive) support 8-, 16-, and 32-bit data accesses. All other McBSP registers are limited to 32-bit data accesses; 16- and 8-bit data accesses are not allowed and can corrupt register contents.

Table 21-37. McBSP1 Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address

RESERVED																FREE	SOFT	FRST	GRST	XINTM	XSYNCERR	XEMPTY	XRDY	XRST							

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Read returns 0x0.	R	0x000000
9	FREE	Free Running Mode (When this bit is set, the module ignores the Msuspend input) 0x0: Free running mode is disabled 0x1: Free running mode is enabled	RW	0x0
8	SOFT	Soft Bit 0x0: SOFT Mode is disabled: the McBSP module stops its activity immediately following MSuspend assertion. 0x1: SOFT Mode is enabled: the McBSP module freezes its state after completion of the current operation when MSuspend is asserted.	RW	0x0
7	FRST	Frame-Sync Generator Reset 0x0: Frame-synchronization logic is reset. Frame-sync signal FSG is not generated by the sample-rate generator 0x1: Frame-sync signal FSG is generated after (FPER+1) number of CLKG clocks; i.e., all frame counters are loaded with their programmed values	RW	0x0
6	GRST	Sample-Rate Generator Reset 0x0: SRG is reset 0x1: SRG is pulled out of reset. CLKG is driven as per programmed value in SRG registers (SRGR[1,2])	RW	0x0
5:4	XINTM	Transmit Interrupt Mode (legacy) 0x0: Transmit interrupt is driven by XRDY 0x1: Transmit interrupt generated by end-of-frame 0x2: Transmit interrupt generated by a new frame synchronization 0x3: Transmit interrupt generated by XSYNCERR	RW	0x0
3	XSYNCERR	Transmit Synchronization Error (writing 0 to this bit clear the legacy transmit interrupt if asserted due to XSYNCERROR condition) 0x0: No synchronization error 0x1: Synchronization error detected by McBSP	RW	0x0
2	XEMPTY	Transmit Shift Register XSR Empty 0x0: XSR is empty 0x1: XSR is not empty	R	0x0
1	XRDY	Transmitter ready 0x0: Transmitter is not ready. 0x1: Transmitter is ready for new data in DXR	R	0x0
0	XRST	Transmitter reset. This resets and enables the transmitter. 0x0: The serial port transmitter is disabled and in reset state. 0x1: The serial port transmitter is enabled.	RW	0x0

RESERVED																GSYNC	CLKSP	CLKSM	FSGM	FPER											

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Read returns 0x0.	R	0x0000
15	GSYNC	Sample Rate Generator Synchronization Only used when the external clock (CLKS) drives the SRG clock (CLKSM=0) 0x0: The SRG clock (CLKG) is free running. 0x1: The SRG clock (CLKG) is running. But CLKG is resynchronized and frame-sync signal (FSG) is generated only after detecting the receive frame-synchronization signal (FSR). Also, frame period, FPER, is a don't care because the period is dictated by the external frame-sync pulse.	RW	0x0
14	CLKSP	CLKS Polarity Clock Edge Select Only used when the external clock CLKS drives the SRG clock (CLKSM=0). 0x0: Rising edge of CLKG and FSG. 0x1: Falling edge of CLKG and FSG.	RW	0x0
13	CLKSM	McBSP SRG Clock Mode 0x0: SCLKME=0: SRG clock derived from the CLKS pin. SCLKME=1: SRG clock derived from the CLKR input pin. 0x1: SCLKME=0: SRG clock derived from the McBSPi_ICLK clock. SCLKME=1: SRG clock derived from the CLKX input pin.	RW	0x1
12	FSGM	Sample Rate Generator Transmit Frame-Synchronization Mode Used when FSXM=1 in the PCR. 0x0: Transmit frame-sync signal (FSX) is generated when transmit buffer is not empty. When FSGM=0, FPER and FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition). 0x1: Transmit frame-sync signal driven by the SRG frame-sync signal, FSG.	RW	0x0
11:0	FPER	Frame Period. This value + 1 determines when the next frame-sync signal becomes active. Range: 1 to 4096 CLKG periods	RW	0x000

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Read returns 0x0.	R	0x00000
14	IDLE_EN	Idle enable. This bit allows stopping all the clocks in the McBSP module. (legacy) 0x0: The McBSP is running 0x1: The clocks in the McBSP are shut off when both IDLE_EN=1 and his power domain is in idle mode (Force idle or Smart idle)	RW	0x0
13	XIOEN	Transmit General Purpose I/O Mode only when XRST=0 in SPCR[1,2] (legacy) 0x0: DX, FSX and CLKX are configured as serial port pins and do not function as general-purpose I/Os. 0x1: DX pin is a general purpose output. FSX and CLKX are general purpose I/Os. These serial port pins do not perform serial port operation.	RW	0x0
12	RIOEN	Receive General Purpose I/O Mode when RRST=0 in SPCR[1,2] (legacy) 0x0: DR, FSR, CLKR and CLKS are configured as serial port pins and do not function as general-purpose I/Os. 0x1: DR and CLKS pins are general purpose inputs; FSR and CLKR are general purpose I/Os. These serial port pins do not perform serial port operation. The CLKS pin is affected by a combination of RRST and RIOEN signals of the receiver.	RW	0x0
11	FSXM	Transmit Frame-Synchronization Mode 0x0: Frame-synchronization signal derived from an external source 0x1: Frame synchronization is determined by the SRG frame-synchronization mode bit FSGM in SRGR2.	RW	0x0
10	FSRM	Receive Frame-Synchronization Mode 0x0: Frame-Synchronization pulses generated by an external device. FSR is an input pin. 0x1: Frame synchronization generated internally by SRG. FSR is an output pin except when GSYNC=1 in SRGR.	RW	0x0

Bits	Field Name	Description	Type	Reset
9	CLKXM	<p>Transmitter Clock Mode</p> <p>When digital loop-back mode set (McBSPi.MCBSPLP_XCCR_REG[5] DLB=1), CLKXM bit is ignored. The internal transmit clock (not the mcbspi_clkx pin) is driven by the internal SRG and mcbspi_clkx pin is in high-impedance.</p> <p>0x0: Transmitter clock is driven by an external clock with CLKX as an input pin.</p> <p>0x1: CLKX is an output pin and is driven by the internal SRG.</p>	RW	0x0
8	CLKRM	<p>Receiver Clock Mode</p> <p>When digital loop-back mode set (McBSPi.MCBSPLP_XCCR_REG[5] DLB=1), CLKRM bit is ignored. The internal receive lock (not the mcbsp1_clkr pin) is driven by the internal SRG and mcbsp1_clkr pin is in high-impedance.</p> <p>0x0: Receive clock is an input driven by an external clock with CLKR as an input pin.</p> <p>0x1: CLKR is an output pin and is driven by the internal SRG.</p>	RW	0x0
7	SCLKME	<p>The frequency of CLKG is: $\text{CLKG frequency} = (\text{Input clock frequency}) / (\text{CLKGDV} + 1)$</p> <p>SCLKME is used in conjunction with the CLKSM bit to select the input clock:</p> <p>0x0: CLKSM = 0: Signal on CLKS pin CLKSM = 1: McBSPi_ICLK clock</p> <p>0x1: CLKSM = 0: Signal on CLKR pin CLKSM = 1: Signal on CLKX pin</p>	RW	0x0
6	CLKS_STAT	<p>CLKS pin status. Reflects value on CLKS pin when selected as a general purpose input. <small>(legacy)</small></p> <p>0x0: The signal on the CLKS pin is low</p> <p>0x1: The signal on the CLKS pin is high</p>	R	0x0
5	DX_STAT	<p>DX pin status. Reflects value driven on to DX pin when selected as a general purpose output. <small>(legacy)</small></p> <p>0x0: Drive the signal on the DX pin low</p> <p>0x1: Drive the signal on the DX pin high</p>	RW	0x0
4	DR_STAT	<p>DR pin status. Reflects value on DR pin when selected as a general purpose input. <small>(legacy)</small></p> <p>0x0: The signal on DR pin is low</p> <p>0x1: The signal on DR pin is high</p>	R	0x0
3	FSXP	<p>Transmit Frame-Synchronization Polarity</p> <p>0x0: Frame-synchronization pulse FSX is active high</p> <p>0x1: Frame-synchronization pulse FSX is active low</p>	RW	0x0
2	FSRP	<p>Receive Frame-Synchronization Polarity</p> <p>0x0: Frame-synchronization pulse FSR is active high</p> <p>0x1: Frame-synchronization pulse FSR is active low</p>	RW	0x0
1	CLKXP	<p>Transmit Clock Polarity</p> <p>0x0: Transmit data driven on rising edge of CLKX</p> <p>0x1: Transmit data driven on falling edge of CLKX</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
0	CLKRP	Receive Clock Polarity 0x0: Receive data sampled on falling edge of CLKR 0x1: Receive data sampled on rising edge of CLKR	RW	0x0

RESERVED			XTHRESHOLD

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Read returns 0x0.	R	0x000000
10:0 ⁽¹⁾	XTHRESHOLD	Transmit buffer threshold value. The DMA request (if enabled) of interrupt assertion (if enabled) is triggered if the number of free locations in the transmit buffer are above or equal to the XTHRESHOLD value + 1. Also, this value (XTHRESHOLD value + 1) indicates the number of words transferred during a transmit data DMA request, if transmit DMA is enabled.	RW	0x00

⁽¹⁾ XTHRESHOLD is an 11-bit field for McBSP2 only. For other McBSPs, XTHRESHOLD is an 8-bit field (bits 7 to 10 are reserved). In other words, the other McBSPs are limited to a FIFO width of 0x7F.

RESERVED																RTHRESHOLD															

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Read returns 0x0.	R	0x000000
10:0 ⁽¹⁾	RTHRESHOLD	Receive buffer threshold value. The DMA request (if enabled) of interrupt assertion (if enabled) is triggered if the number of occupied locations in the receive buffer are above or equal to the RTHRESHOLD value + 1. Also, this value (RTHRESHOLD value + 1) indicates the number of words transferred during a receive data DMA request, if receive DMA is enabled.	RW	0x00

⁽¹⁾ RTHRESHOLD is an 11-bit field for McBSP2 only. For other McBSPs, RTHRESHOLD is an 8-bit field (bits 7 to 10 are reserved). In other words, the other McBSPs are limited to a FIFO width of 0x7F.

RESERVED																EXTCLKGATE	PPCONNECT	DXENDLY	XFULL_CYCLE	RESERVED				DLB	RESERVED	XDMAEN	RESERVED	XDISABLE			

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Read returns 0x0.	R	0x0000
15	EXTCLKGATE	<p>External clock gating enable (CLKX and FSX master only). When this bit is set and the transmit clock and FSX are set as output, the CLKX is enabled when FSX is active plus 3 clock cycles after (clock is provided for FWID + 4 clock cycles, assuming that the FSX width, active, is FWID + 1 clock cycles); outside this window the external transmit clock is gated. The receive use the same gated transmit clock and transmit frame synchronization signals regardless of the CLKRM/FSRM settings. When using this mode the frame synchronization signal must be active during reception of the entire frame (FWID must be programmed accordingly) to ensure the proper receive process, which requires at least 3 cycles after the frame complete to transfer the data into the receive buffer.</p> <p>0x0: External clock gating disabled. 0x1: External clock gating enable.</p>	RW	0x0
14	PPCONNECT	<p>Pair to pair connection. When set the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output.</p> <p>0x0: non Pair-to-pair connection. The DX pin will go to high-impedance state when there is no frame to transmit.</p> <p>0x1: Pair-to-pair connection. When set, the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output. This means the DX pin will be driven outside valid frame window. In that case, data sent by McBSP module during inactive channel are not guaranteed.</p>	RW	0x0
13:12	DXENDLY	<p>When McBSPi.MCBSPLP_SPCR1_REG[7] DXENA bit is set to one, this field selects the added delay as follow:</p> <p>0x0: 13 ns 0x1: 18 ns (default) 0x2: 24 ns 0x3: 30 ns</p>	RW	0x1
11	XFULL_CYCLE	<p>Transmit full cycle mode select:</p> <p>0x0: McBSP module operates in transmit half-cycle mode (transmit frame synchronization is sampled by the opposite edge of the clock used to drive transmit data)</p> <p>0x1: McBSP module operates in transmit full-cycle mode (transmit frame synchronization is sampled by the same edge of the clock used to drive transmit data)</p>	RW	0x0
10:6	RESERVED	Read returns 0x0.	R	0x00
5	DLB	Digital Loop-Back	RW	0x0
		0x0: No DLB 0x1: DLB		
4	RESERVED	Read returns 0x0.	R	0x0

Bits	Field Name	Description	Type	Reset
3	XDMAEN	Transmit DMA Enable bit. When set to zero this bit will gate the external transmit DMA request, without resetting the DMA state machine. It is recommended to change this bit value only during transmit reset. 0x0: When set to zero this bit will gate the external transmit DMA request, 0x1: When set to one this bit will NOT gate the external transmit DMA request,	RW	0x1
2:1	RESERVED	Read returns 0x0.	R	0x0
0	XDISABLE	Transmit Disable bit. When this bit is set the transmit process will stop at the next frame boundary. 0x0: The transmit process will NOT stop at the next frame boundary. 0x1: The transmit process will stop at the next frame boundary.	RW	0x0

10:0 ⁽¹⁾	RBUFFSTAT	Receive Buffer Status (indicates the number of occupied locations in the receive buffer). The RBUFFSTAT value reflects the buffer status on the L4 clock domain and it can be smaller than the real number of the occupied locations which are seen by the receive state machine.	R	0x00

⁽¹⁾ RBUFFSTAT is an 11-bit field in McBSP2. For other McBSPs, RBUFFSTAT is an 8-bit field (bits 8 to 10 are reserved).

High-Speed USB Host Subsystem and High-Speed USB OTG Controller

This chapter describes the high-speed universal serial bus (USB) host subsystem and the high-speed USB On-The-Go (OTG) controller of the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
22.1 High-Speed USB OTG Controller	3239
22.2 High-Speed USB Host Subsystem	3262

Overview

The device contains two USB modules:

- A High-Speed USB OTG Controller (see [Section 22.1, High-Speed USB OTG Controller](#))
- A High-Speed USB Host Subsystem (see [Section 22.2, High-Speed USB Host Subsystem](#))

Figure 22-1. USB Modules Overview

usb-035

22.1 High-Speed USB OTG Controller

NOTE: The High-Speed USB OTG Controller is an instantiation of the MUSBMHDRC from Mentor Graphics Corporation.

This document contains materials that are ©2003-2007 Mentor Graphics Corporation.

Mentor Graphics is a registered trademarks of Mentor Graphics Corporation or its affiliated companies in the United States and other countries.

22.1.1 High-Speed USB OTG Controller Overview

The High-Speed USB OTG dual-role-device (DRD) link controller supports the following modes:

- USB 2.0 peripheral (function controller) in high/full speed (480/12 Mbps, respectively)
- USB 2.0 host in high/full/low speed (480/12/1.5 Mbps respectively), with one downstream port but multipoint capability when a hub is connected to it (split transaction support, etc.)
- USB 2.0 OTG DRD in high/full speed, with HNP and SRP support.

The high-speed USB controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode).

Figure 22-2 highlights the high-speed USB controller.

Figure 22-2. High-Speed USB Controller Highlight

22.1.1.1 Main Features

The high-speed USB controller has the following features:

- Operates either as the function controller of a high-/full-speed USB peripheral or as the host/peripheral in point-to-point or multipoint communications with other USB functions

- Complies with the USB 2.0 standard for high-speed (480 Mbps) functions and with the OTG supplement (Revision 1.0a)
- Includes all transfer types: Control, bulk, isochronous, interrupt
- Supports SRP and HNP
- Supports suspend/resume and remote wakeup
- Supports high-bandwidth isochronous and interrupt transfers
- Contains one PHY (physical layer) interface: ULPI interface (12/8-pin version)
- 15 transmit endpoints and 15 receive endpoints in addition to control endpoint 0
- Each endpoint has its own FIFO, with the following properties:
 - Implemented within a single, 16K-byte internal RAM
 - Can be dynamically sized by software
 - Can be configured to hold multiple packets (up to 8192 bytes per FIFO)
 - Can be accessed either by direct access or by DMA controller
- Software connect/disconnect option for peripheral
- Performs all transaction scheduling in hardware

22.1.2 High-Speed USB OTG Controller Environment

Figure 22-3 shows a typical application using the high-speed USB controller.

Figure 22-3. High-Speed USB Controller Typical Application System

usb-002

The high-speed USB controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode). A mini A-B external receptacle allows the connection of an external device.

The current implementation of ULPI includes a method for manual, software-controlled generation of PHY-side register accesses supporting the following features:

- Access to vendor-specific or optional PHY-side registers
- Carkit operation (including interrupt, PHY-side registers)
- Access to vendor ID, product ID, scratch and debug registers

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY clock (SDR mode); the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edge (DDR mode).

The TI high-speed USB controller supports only the 12-pin, 8-bit version ULPI interface.

The 12-pin/8-bit data SDR ULPI interface is selected through the USBOTG.OTG_INTERFSEL[1:0] PHYSEL field and must be set to 0x1.

22.1.2.1 High-Speed USB Controller Functional Interfaces

22.1.2.1.1 Basic High-Speed USB Controller Pins

Figure 22-4 shows the high-speed USB controller functional interface.

Figure 22-4. High-Speed USB Controller Functional Interface Signals

usb-003

22.1.2.1.2 High-Speed USB Controller Interface Description

Table 22-1 describes the I/O of the high-speed USB controller interface.

Table 22-1. Input/Output Description

Signal Name	I/O ⁽¹⁾	Description	Reset Value

hsusb0_data7	I/O	Bidirectional DATA7	N/A

⁽¹⁾ I = Input; O = Output

22.1.3 High-Speed USB OTG Controller Integration

The high-speed USB controller is connected to L3 interconnect master (initiator) and slave (target) interfaces and L4-Core interconnect. The L3 interconnect generates data traffic within the device. The L4-Core interconnect is a configuration port for register setting.

Figure 22-5 highlights the high-speed USB controller integration in the device.

Figure 22-5. High-Speed USB Controller Integration

usb-004

22.1.3.1 Clocking, Reset, and Power-Management Scheme

22.1.3.1.1 Clocks

22.1.3.1.1.1 Module Clocks

Three clocks are provided to the high-speed USB controller, as shown in Table 22-2.

Table 22-2. USB Clocks

Attributes	Frequency	Name	Mapping	Comments
Functional clock	60 MHz	USBHS_FCLK	hsusb0_clk	Source is external transceiver (ULPI)
Master Interface clock	Depending on PRCM register settings	USBHS_MICLK	CORE_L3_ICLK	Source is PRCM module

Table 22-2. USB Clocks (continued)

Attributes	Frequency	Name	Mapping	Comments
Slave Interface clock	Depending on PRCM register settings	USBHS_SICLK	CORE_L4_ICLK	Source is PRCM module

22.1.3.1.1.2 Master Interface Clock

The master interface clock USBHS_MICLK comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN1_CORE[4]:

- 0: Disabled
- 1: Enabled

and PRCM.CM_AUTOIDLE1_CORE[4] (enables/disables automatic control of the interface clock)-see Table 22-3.

Table 22-3. High-Speed USB Interface Clock

PRCM.CM_AUTOIDLE1_CORE[4]	PRCM.CM_ICLKEN1_CORE[4]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

22.1.3.1.1.3 Functional Clock

The functional clock (60MHz), USBHS_FCLK, comes from the external ULPI transceiver through the hsusb0_clk input pin.

22.1.3.1.2 Resets

The high-speed USB controller can be reset either by the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in the module.

22.1.3.1.2.1 Hardware Reset

The high-speed USB controller is attached to the CORE power domain: The CORE_RST signal resets the module (see [Chapter 3, Power, Reset, and Clock Management](#)). The hardware reset signal has a global reset action on the high-speed USB controller.

22.1.3.1.2.2 Software Reset

The high-speed USB controller has a software reset through the USBOTG.OTG_SYSConfig[1] SOFTRESET bit (0: Normal mode, 1: Module is reset).

This bit controls the software reset. Writing 1 to this bit resets the module. The bit value 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.

22.1.3.1.3 Power-Management Scheme

22.1.3.1.3.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB controller power management is applied only to the interface clock domain. The USB functional clock (60 MHz), USBHS_FCLK, is controlled by the transceiver and is responsible only for a very small percentage of the module overall power consumption.

The high-speed USB controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

22.1.3.1.3.2 System Power Management

Master Interface Power Management

The high-speed USB controller can choose to go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB controller has a MSTANDBY handshake mechanism with the PRCM module (see Figure 22-5).

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when there is no USB activity and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module to go to standby state based on the [USBOTG.OTG_SYSCONFIG\[13:12\]](#) MIDLEMODE field.

- Smart standby

The high-speed USB controller is configured in smart-standby mode ([USBOTG.OTG_SYSCONFIG\[13:12\]](#) MIDLEMODE field = 0x2). The module is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

- Force standby

The high-speed USB controller is configured in force-standby mode ([USBOTG.OTG_SYSCONFIG\[13:12\]](#) MIDLEMODE field = 0x0).

- When the high-speed USB controller operates as a host: The [USBOTG.POWER\[1\]](#) SUSPENDMODE bit is set to 1 to bring the module to low-power mode (suspend mode). After this setting, the high-speed USB controller waits for its idle state. The [USBOTG.OTG_FORCESTDBY\[0\]](#) ENABLEFORCE bit must be set to 1 to assert MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the following two cases:

- Remote wakeup causes a RESUME interrupt
- Set the [USBOTG.POWER\[3\]](#) RESET bit to 1.
- Write 0 to the [USBOTG.OTG_FORCESTDBY\[0\]](#) ENABLEFORCE bit.
OR
- Set the [USBOTG.POWER\[3\]](#) RESET bit to 1.
- Write 0 to the [USBOTG.OTG_FORCESTDBY\[0\]](#) ENABLEFORCE bit.

- When the high-speed USB controller operates as a peripheral: When the USB bus is idle for 3 ms, a SUSPEND interrupt is generated by the high-speed USB controller. The [USBOTG.OTG_FORCESTDBY\[0\]](#) ENABLEFORCE bit must be set to 1 to enable the MSTANDBY signal. The high-speed USB controller then asserts MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the

following two cases:

- Set the USBOTG.POWER[2] RESUME bit to 1.
- Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit.
OR
- RESET interrupt is generated by the high-speed USB controller.
- Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit.

When MSTANDBY is deasserted as a consequence of the previous register access, the module waits for MWAIT deassertion before a DMA transfer is started.

- No standby

The high-speed USB controller is configured in no-standby mode (USBOTG.OTG_SYSConfig[13:12] MIDLEMODE field = 0x1). The module never enters standby mode (that is, MSTANDBY is never asserted).

Table 22-4 describes the high-speed USB master interface power management modes.

Table 22-4. High-Speed USB Master Interface Power Management Modes

Power Management Mode Requested by the PRCM	USBOTG.OTG_SYSConfig[13:12] MIDLEMODE Field
Force-standby	0x0
No-standby	0x1
Smart-standby	0x2
Reserved	0x3

Slave Interface Power Management

The high-speed USB controller can be configured through the USBOTG.OTG_SYSConfig[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- Smart-Idle Mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock USBHS_ICLK is disabled (PRCM register bit PRCM.CM_ICLKEN1_CORE[4] set to 0) or under automatic control (PRCM register bits PRCM.CM_ICLKEN1_CORE[4] and PRCM.CM_AUTOIDLE1_CORE[4] both set to 1)
- L4 interface clock idle transitions:

Configured in smart-idle mode (USBOTG.OTG_SYSConfig[4:3] SIDLEMODE field = 0x2), the high-speed USB controller checks for no ongoing activity. The idle acknowledge then is asserted and the module waits for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the module is ready to issue a wake-up request. If a wake-up condition occurs, the high-speed USB controller exits from idle mode if the USBOTG.OTG_SYSConfig[2] ENABLEWAKEUP bit is set to 1 (wake-up capability enabled) and the PRCM register bit PRCM.PM_WKEN1_CORE[4] is also set to 1.

- Force-Idle Mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock USBHS_ICLK is disabled (PRCM register bit PRCM.CM_ICLKEN1_CORE[4] set to 0) or under automatic control (PRCM register bits PRCM.CM_ICLKEN1_CORE[4] and PRCM.CM_AUTOIDLE1_CORE[4] both set to 1)
- The L4 interface clock idle transitions:

Configured in force-idle mode (USBOTG.OTG_SYSConfig[4:3] SIDLEMODE field = 0x0), the high-speed USB controller waits unconditionally for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the wake-up feature is

totally inhibited.

- No-Idle Mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock(s) USBHS_ICLK are disabled (PRCM register bit PRCM.CM_ICLKEN1_CORE[4] set to 0) or under automatic control (PRCM register bits PRCM.CM_ICLKEN1_CORE[4] and PRCM.CM_AUTOIDLE1_CORE[4] both set to 1)
 - L4 interface clock idle transitions
- Configured in no-idle mode (USBOTG.OTG_SYS CONFIG[4:3] SIDLEMODE field = 0x1), the high-speed USB controller module does not go to idle mode and the idle acknowledge is never sent.

[Table 22-5](#) describes the high-speed USB slave interface power management modes.

Table 22-5. High-Speed USB Slave Interface Power Management Modes

Power Management Mode Requested by the PRCM	USBOTG.OTG_SYS CONFIG[4:3] SIDLEMODE Field
Force-idle	0x0
No-idle	0x1
Smart-idle	0x2
Reserved	0x3

NOTE: The high-speed USB controller standby status can be checked by the PRCM module register bit CM_IDLEST1_CORE[4].

- 0: High-Speed USB is active.
- 1: High-Speed USB is in standby mode.

The high-speed USB controller wake-up status can be checked by the PRCM module register bit PM_WKST1_CORE[4].

- Read 0: Wakeup has not occurred or was masked.
- Read 1: Wakeup has occurred.
- Write 0: Status bit unchanged.
- Write 1: Status bit is cleared to 0.

22.1.3.1.3.3 Local Power Management

The high-speed USB controller has local power management by internal clock gating features:

- Internal interface clock autogating: Clock for the L3 interconnect logic can be gated when the module is not accessed, if the USBOTG.OTG_SYS CONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock. This bit is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

22.1.3.1.4 Power Domain

The high-speed USB controller is attached to the CORE power domain (see [Chapter 3, Power, Reset, and Clock Management](#)).

22.1.3.2 Hardware Requests

22.1.3.2.1 Interrupt Requests

[Table 22-6](#) lists the interrupt lines that are driven out from the high-speed USB controller to the MPU subsystem INTC.

Table 22-6. High-Speed USB Interrupts

Name	Mapping	Comments
HS USB Controller Interrupt		
HSUSB_MC_NINT	M_IRQ_92	Destination is MPU subsystem interrupt controller
HS USB DMA Controller Interrupt		
HSUSB_DMA_NINT	M_IRQ_93	Destination is MPU subsystem interrupt controller

22.1.3.2.2 *IDLE Handshake Protocol*

The PRCM handles an IDLE handshake protocol for the high-speed USB controller. The IDLE handshake protocol allows the PRCM requiring the high-speed USB controller to enter idle mode. The high-speed USB controller acknowledges when it is ready.

22.1.3.2.3 *MSTANDBY Handshake Protocol*

The PRCM module handles an MSTANDBY handshake protocol for the high-speed USB controller, which initiates the MSTANDBY handshake to inform the PRCM module when it enters standby mode and does not generate traffic on interconnect.

22.1.3.2.4 *Wake-Up Request*

The high-speed USB controller generates a wake-up request signal (UBSHS_SWAKEUP) to the PRCM module.

22.1.4 High-Speed USB OTG Controller Functional Description

22.1.4.1 Inventra™ MUSBMHDRC

The core functionality of the module is provided by a third-party IP, the Inventra MUSBMHDRC from Mentor Graphics Corporation.

The high-speed USB controller is basically the appropriate adaptation/integration of this IP to comply with TI requirements.

The high-speed USB controller includes the following:

- MUSBMHDRC (USB 2.0 controller)
- Master and slave bridges for conversion AHB to L3 interconnect and L3 interconnect to AHB
- Two memories (total of 16Kbytes; available for various endpoints)
- Reset and clock generation

[Figure 22-6](#) shows the high-speed USB controller.

Figure 22-6. High-Speed USB Controller

usb-005

22.1.4.2 Configuration

The Mentor Graphics IP RTL MUSBMHDRC can be configured to generate some customized hardware. Those options are all hard-wired and cannot be reprogrammed in the case of the TI High-Speed USB controller.

The following options are selected:

- 8-bit internal data path processing width (mandated by the use of ULPI)
- 32-bit vcontrol/vstatus support
- External charge pump: Hacked
- Software connect/disconnect supported
- Little-endian and big-endian byte ordering
- Eight DMA channels (with internal DMA initiator implemented)
- Dynamic FIFO sizing enabled
- 16K bytes RAM buffer
- 15 IN/OUT endpoints in addition to control endpoint 0
- IN/OUT bulk packet splitting/combining enabled
- High-bandwidth IN/OUT isochronous support enabled (see *Universal Serial Bus Specification Revision 2.0*)

22.1.4.3 Basic Operation

This section provides an overview of the module basic operation.

To implement the most time-critical functions in hardware, the module provides all of the encoding, decoding, and checking required to send and receive USB packets-interrupting the MPU only when endpoint data is successfully transferred. Generally, the following steps are performed:

22.1.4.3.1 Module Initialization

First, the firmware must do the overall initialization of the module by configuring the interrupts, the DMA controller, and the individual endpoints.

The specific items of a configuration are for each endpoint:

- Direction TX/RX
- Speed: High/full/low
- Special host settings when used in host mode (function address/hub parameters, etc.)
- Transaction protocol: Control/isochronous/bulk/interrupt
- Maximum packet size, that can be transferred through the endpoint
- Whether DMA is required (DMA enable)
- DMA mode
- Start address of the endpoint FIFO within the RAM block
- Maximum packet size allowed
- Whether double-buffering is required. This and the previous option define the amount of space that must be allocated to the FIFO. In the case of double-buffering, the FIFO size is doubled; therefore, the maximum supported size is 8196 bytes for the endpoint FIFOs.

NOTE: On the system level, it must be ensured that the reset and the interface are selected before the 60-MHz functional clock (USBHS_FCLK) is applied to the module. Correct functionality is not ensured if either a reset deassertion or a change in the interface selection occurs when the functional clock USBHS_FCLK is already running.

22.1.4.3.1.1 MSTANDBY Deassertion

MSTANDBY is asserted during reset and continues to be 1 after reset. The high-speed USB controller does not perform master interface transactions until this signal is deasserted. Firmware must follow these steps to begin normal operations on the master interface bus:

- Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit.
- Put the high-speed USB controller into no-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x1) and no-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDLEMODE field = 0x1).

Even though ENABLEFORCE is 0, MSTANDBY remains asserted until the high-speed USB controller core is out of idle state.

22.1.4.3.2 Transaction Handling

Depending on whether the module is in the host or peripheral mode, an RX endpoint is assigned to IN or OUT transactions, respectively. Similarly, a TX endpoint is used for IN transactions in the peripheral mode and for OUT transactions in the host mode. When a transaction is complete, the appropriate endpoint interrupt is generated (if enabled).

When a transaction is handled through an RX endpoint, the received packet is placed in the RX FIFO, and the appropriate RX endpoint interrupt is generated. The packet can then be unloaded from the FIFO either manually (that is, by the MPU) or by the DMA. Although an RX endpoint is always active for a peripheral, in host mode the transaction must first be initiated by setting the appropriate request flag (REQPKT). This indicates to the transaction scheduler that there is an active transaction on this endpoint, which requires an IN token to be sent to the target function.

When a transaction is handled through a TX endpoint, the packet to send is loaded into the TX FIFO either manually (that is, by the MPU) or by the DMA. The transaction then must be initiated by setting the appropriate ready flag (TXPKTRDY) to indicate the availability of the new packet. When the packet is successfully sent (scheduled according to the protocol rules), the appropriate TX interrupt is generated.

22.1.4.4 Optional Features

This section gives a quick overview of the optional features that are available, depending on the endpoint configuration.

22.1.4.4.1 Double Packet Buffering

When double packet buffering is enabled (by setting the MSB of the FIFOSZ register two data packets can be stored in the FIFO. This option can be set for both the TX and RX endpoints in both the peripheral and host mode. For a TX endpoint, double-buffering means that up to two packets can be loaded into the FIFO awaiting transmission; for an RX endpoint, one packet can be received while another is being read.

Double packet buffering is especially advisable for isochronous transactions to avoid underrun or overrun errors.

The high-speed USB controller provides dynamic FIFO sizing with an overall RAM size of 16K bytes, which can then be allocated to the different endpoints when the module is initialized. The maximum size of an endpoint FIFO is 4096 bytes for single packet buffering and 8192 bytes for double packet buffering.

The firmware must ensure that a block of RAM is properly assigned to all TX and RX endpoints, considering the total RAM size and the maximum packet size set for the endpoint.

22.1.4.4.2 High-Speed USB OTG Support for Big Endian

In the example in [Figure 22-7](#), the high-speed USB OTG controller module is configured as a USB device and is connected to a standard USB host. The two interconnect interfaces of the high-speed USB OTG controller connect it to the system bus. The register read/write is performed through the interconnect slave interface (control path). The data transfer to/from system memory takes place through the interconnect master interface (data path).

The data transfer on the USB is always in little-endian mode, but on interconnect it can be in little- or big-endian mode, as shown in [Figure 22-7](#).

Figure 22-7. High-Speed USB OTG Controller Endianess

usb-036

Big-endian support in the high-speed USB OTG controller may or may not require byte-swapping in the data path. Byte-swapping is performed based on the unit size of data. For example, if multiple bytes are packed into one 32-bit word, these bytes must be swapped in a big-endian interconnect. On the other hand, if the data is only a 32-bit word (for example, a 32-bit descriptor pointer in a memory buffer), the bytes in the word must not be swapped in big-endian mode.

In the high-speed USB OTG controller, the unit size of descriptors(descriptor pointers is 32 bits and that of the USB data is 8 bits. Four 8-bit USB data are packed to form a 32-bit word. This 32-bit data requires byte-swapping, whereas the descriptorsdescriptor pointers do not require the same.

NOTE: Byte-swapping is not required in the control path (slave interface).

The OCP master interface (a submodule within the OCP wrapper) supports big-endian conversion by setting the OTG_BIGENDIAN[0] BIG_ENDIAN bit to 0x1.

For interconnect write transactions, the data word is swapped as shown in [Table 22-7](#) before its output on the interconnect master interface. In case of an interconnect read transaction, the received data is swapped before its output on the AHB master interface of the MUSBMHDRC core. The OCP MByteEn is swapped before the command is issued on the OCP master interface. The OCP MAddr is always aligned to the interconnect data size (32 bits). Therefore, the OCP MAddr is always word-aligned.

Table 22-7. Interconnect Data and MByteEn in Little- and Big-Endian Modes

Unit Size of Data	AHB Size (of Packed/Nonpacked Data)	AHB Start Address Offset (Always in Little-Endian Mode)	OCP MByteEn in Little-Endian Mode	OCP MByteEn in Big-Endian Mode	OCP Data in Little-Endian Mode	OCP Data in Big-Endian Mode
Byte	Byte	0	0001	1000	xxxb0	b0xxx
Byte	Byte	1	0010	0100	xxb0x	xb0xx
Byte	Byte	2	0100	0010	xb0xx	xxb0x
Byte	Byte	3	1000	0001	b0xxx	xxxb0
Byte	Half-word	0	0011	1100	xxb1b0	b0b1xx

Table 22-7. Interconnect Data and MByteEn in Little- and Big-Endian Modes (continued)

Unit Size of Data	AHB Size (of Packed/Nonpacked Data)	AHB Start Address Offset (Always in Little-Endian Mode)	OCP MByteEn in Little-Endian Mode	OCP MByteEn in Big-Endian Mode	OCP Data in Little-Endian Mode	OCP Data in Big-Endian Mode
Byte	Half-word	2	1100	0011	b1b0xx	xxb0b1
Byte	Word	0	1111	1111	b3b2b1b0	b0b1b2b3
Half-word	Half-word ⁽¹⁾	0	0011	1100	xxb1b0	b1b0xx
Half-word	Half-word ⁽¹⁾	2	1100	0011	b1b0xx	xxb1b0
Half-word	Word ⁽¹⁾	0	1111	1111	b3b2b1b0	b1b0b3b2
Word	Word ⁽²⁾	0	1111	1111	b3b2b1b0	b3b2b1b0

⁽¹⁾ Not a likely scenario for high-speed USB OTG controller

⁽²⁾ Corresponds to descriptor and descriptor pointer. No bytes are packed to form a word; therefore, no byte-swapping is done in this case.

22.1.4.4.3 DMA

The high-speed USB controller has an internal DMA controller for efficient loading/unloading of the endpoint FIFOs.

If the DMA is enabled for a TX endpoint, a DMA transfer occurs whenever the endpoint can accept another packet in its FIFO (that is, the DMA controller loads the packets into the FIFO without processor intervention).

If the DMA is enabled for an RX endpoint, a DMA transfer occurs whenever the endpoint has a packet in its FIFO (that is, the DMA CONTROLLER unloads the packets from the FIFO without processor intervention).

The high-speed USB controller supports two DMA request modes, which also affects the generation of endpoint interrupts.

- DMA request mode 0 is especially advisable for isochronous transfers but can also be used for bulk and interrupt transfers.
- DMA request mode 1 is mainly valuable for bulk transfers, where typically a large block of data is split into a series of packets of the maximum size.

22.1.4.4.3.1 DMA Request Mode 0

For RX endpoints, the DMA transfer is initiated when a data packet is available in the endpoint FIFO. The appropriate endpoint interrupt is also generated after the packets are received.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is also generated to prompt the loading of the packets.

22.1.4.4.3.2 DMA Request Mode 1

For RX endpoints the DMA transfer is initiated only when the received packet is the maximum packet size (as set in the RXMAXP register for the corresponding endpoint). The appropriate endpoint interrupt is generated only when the received packet is a short packet (that is, one less than the maximum packet size); otherwise, it is suppressed.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is suppressed.

22.1.4.4.3.3 Internal DMA Controller

The high-speed USB controller has an internal DMA controller to perform DMA transfers acting as host on the L3 interconnect. The DMA controller has eight channels, which can be independently programmed based on the following configuration options:

- DMA enable

- Direction (DMA write/DMA read)
- DMA mode (transfer one or more packets)
- Interrupt enable
- Endpoint number
- L3 interconnect memory address (32 bits)
- Byte count

The DMA controller can issue single accesses (8-, 16-, or 32-bit) and also bursts ($4 \times 32\text{-bit}$, $8 \times 32\text{-bit}$, or $16 \times 32\text{-bit}$) on the L3 interconnect. The start address provided to the DMA controller must be 32-bit aligned.

22.1.4.5 Automatic Packet Splitting/Combining for Bulk Transfers

The high-speed USB controller offers the facility for bulk endpoints to store larger amounts of data in their FIFOs than can be transferred in a single USB operation. In other words, the module includes a configuration option that, if selected, allows larger data packets to be written to bulk TX endpoints, which are then split into packets of an appropriate size for transfer across the USB. A similar option exists for bulk RX endpoints, which, if selected, causes the module to combine the packet received across the USB into larger data packets before being read by the application software.

The firmware can enable these options by setting the corresponding bits (MPRXE and MPTXE) in the CONFIGDATA register. The necessary packet size information contains the payload size for one transaction and a multiplier defining the maximum number of USB packets. The payload is required to be either 8, 16, 32, 64, or (in case of high-speed transfers) 512 bytes; the multiplier can be any value up to 32.

22.1.4.6 High-Bandwidth Isochronous Endpoints

In the high-speed mode, isochronous endpoints can transfer up to three USB packets in any microframe with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per microframe (see *Universal Serial Bus Specification Revision 2.0*).

For TX endpoints, the high-speed USB controller supports this by allowing loading data packets of up to 3072 bytes (that is, 3×1024 bytes) into the associated endpoint FIFO, which is then automatically split into USB packets of the maximum payload, or smaller to be transmitted in one microframe.

For RX endpoints, the module automatically combines all the USB packets received during a microframe into a single packet of up to 3072 bytes (that is, 3×1024 bytes) within the RX FIFO.

The number of USB packets transferred per microframe and the maximum payload in each packet is defined through the appropriate registers (RXMAXP and TXMAXP).

22.1.5 High-Speed USB OTG Controller Basic Programming Model

This section describes only the TI-specific programming model details.

22.1.5.1 High-Speed USB Controller Interface Selection

The TI High-Speed USB controller supports only the 12-pin/8-bit data version ULPI interface (see [Table 22-16](#)).

The 8-pin, 4-bit version ULPI interface and 8-bit UTMI+ Level 3 interface are not supported.

The 12-pin/8-bit data SDR ULPI interface is selected through the USBOTG.[OTG_INTERFSEL\[1:0\]](#) PHYSEL field set to 0x1.

22.1.5.2 Enable Simulation Acceleration Features

The USBOTG.[OTG_SIMENABLE](#) register is dedicated solely for simulation (see [Table 22-18](#)) and is used to reduce timer length and, hence, the time taken for the test bench to run.

This special mode can be active only during simulation and must be disabled for normal operation. The firmware must keep TM1 inactive (reset value) during normal operation. An accidental write to this register can cause a malfunction.

22.1.5.3 Enabling MSTANDBY in Force-Standby Mode

The USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit controls MSTANDBY behavior in force-standby mode only (see [Table 22-20](#)). In this mode, only when the internal core is idle (the module has no activity; that is, the USB is in suspend state) and when 1 is written to this bit, MSTANDBY goes high. Similarly, when ENABLEFORCE is 0 and the internal core is also in a non-idle state, MSTANDBY is deasserted. This bit does not influence MSTANDBY behavior in all other modes, such as no-standby and smart-standby.

22.1.5.4 Power Management Basic Programming Model

This section describes the settings for optimal High-Speed USB controller power management, depending on the use of this module in the application.

Two registers are involved in power management: USBOTG.OTG_SYSCONFIG and USBOTG.OTG_FORCESTDBY.

On reset, the high-speed USB controller has the following configuration:

- Master interface power management is in force-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDLEMODE field = 0x0).
- Slave interface power management is in force-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x0).
- Internal clock autogating feature is disabled (USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit = 0).
- MSTANDBY signal assertion is enabled (USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit = 1).

22.1.5.4.1 High-Speed USB Controller Not Used for Application

In this scenario, the high-speed USB controller is not used by the system software. Default settings must be changed to reduce power consumption. Enabling the internal clock autogating feature cuts off the module internal interface clock as soon as it is no longer required. This is done by setting the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 1.

The optimal configuration when the high-speed USB controller is not used by the application is as follows:

- Master interface power management is in force-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDLEMODE field = 0x0).
- Slave interface power management is in force-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x0).
- Internal clock autogating feature is enabled (USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit = 1).
- MSTANDBY signal assertion enabled (USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit = 1)

22.1.5.4.2 High-Speed USB Controller in Host Mode

When used as a host, the high-speed USB controller must be programmed as follows:

- Master interface power management in smart-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion disabled

The programming sequence must be as follows:

1. Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit to disable the MSTANDBY assertion before programming to smart-standby and smart-idle modes.

2. Set the USBOTG.OTG_SYSConfig[13:12] MIDLEMODE field to 0x2, the USBOTG.OTG_SYSConfig[4:3] SIDLEMODE field to 0x2, and the USBOTG.OTG_SYSConfig[0] AUTOIDLE bit to 0 to program the smart-standby and smart-idle modes. Ensure that internal clock autogating is not enabled while programming smart-idle mode.
3. Set the USBOTG.OTG_SYSConfig[0] AUTOIDLE bit to 1 to cut off the internal clocks to save power.

NOTE: The internal clock autogating feature and smart-idle mode must not be programmed simultaneously.

22.1.5.4.3 High-Speed USB Controller in Peripheral Mode

When used as a peripheral, the high-speed USB controller must be programmed as follows:

- Master interface power management in smart-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion disabled

The programming sequence must be as follows:

1. Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit to disable the MSTANDBY assertion before programming to smart-standby mode.
2. Set the USBOTG.OTG_SYSConfig[13:12] MIDLEMODE field to 0x2, the USBOTG.OTG_SYSConfig[4:3] SIDLEMODE field to 0x2, and the USBOTG.OTG_SYSConfig[0] AUTOIDLE bit to 0 to program the smart-standby and smart-idle modes. Ensure that the internal clock autogating is not enabled while programming the smart-idle mode..
3. Set the USBOTG.OTG_SYSConfig[0] AUTOIDLE bit to 1 to cut off the internal clocks to save power.

NOTE: The internal clock autogating feature and smart-idle mode must not be programmed simultaneously.

22.1.5.4.4 High-Speed USB Controller in Host/Peripheral Mode

When used as a host/peripheral, the high-speed USB controller must be programmed as follows:

- Master interface power management in smart-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion disabled

See [Section 22.1.5.4.2](#) and [Section 22.1.5.4.3](#) for the programming sequence.

As an application required to disable the master interface, the high-speed USB controller can also be programmed as follows:

- Master interface power management in force-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion enabled

The programming sequence must be as follows:

1. Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit to disable the MSTANDBY assertion before programming to smart-standby mode.
2. Set the USBOTG.OTG_SYSConfig[13:12] MIDLEMODE field to 0x0, the USBOTG.OTG_SYSConfig[4:3] SIDLEMODE field to 0x2, and the USBOTG.OTG_SYSConfig[0] AUTOIDLE bit to 0 to program the force-standby and smart-idle modes. Ensure that the internal clock autogating is not enabled while programming smart-idle mode.

3. Set the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit to 1 to enable the MSTANDBY assertion before enabling internal clock autogating feature.
4. Set the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 1 to cut off the internal clocks to save power.

NOTE: The internal clock the autogating feature and smart-idle mode must not be programmed simultaneously.

22.1.6 High-Speed USB OTG Controller Register Manual

As this chapter describes only the TI-specific details, this section presents only the TI-specific registers of the high-speed USB controller.

[Table 22-8](#) lists the base address and address space for the high-speed USB controller.

Table 22-8. High-Speed USB Controller Instance Summary

Module Name	Base Address	Size
USBHS	0x480A B000	4KB

CAUTION

The high-speed USB registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

22.1.6.1 High-Speed USB OTG Controller Registers

22.1.6.1.1 High-Speed USB Register Summary

Table 22-9. High-Speed USB Controller Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	USBHS Physical Address

22.2 High-Speed USB Host Subsystem

NOTE: Copyright ©2004,2005, 2006, 2007, 2008 Synopsys, Inc. All rights reserved. Used with permission.

22.2.1 High-Speed USB Host Subsystem Overview

The high-speed universal serial bus (USB) host subsystem is composed of the high-speed multiport USB host controller and the USBTLL module.

The USB controller is a high-speed multiport USB2.0 host controller. It contains two independent, 3-port host controllers that operate in parallel:

- The EHCI controller, based on the *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*, is in charge of high-speed traffic (480M bit/s), over the ULPI/UTMI interface
- The OHCI controller, based on the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*, is in charge of full-speed/low-speed traffic (12/1.5M bit/s, respectively), over a serial interface

Each of the three device external ports is owned by exactly one and only one of the controllers at any time.

The USBTLL module is a high-speed USB UTMI low-pin interface (ULPI) transceiverless link logic (TLL) adapter. It implements a TLL compatible with a number of USB standard interface protocols. It consists of three channels, defined as independent USB path through the TLL module, which always converts the UTMI+ PHY interface protocol coming from the high-speed USB host controller.

Each USB port (1, 2, and 3) can connect either to an external-to-device chip USB transceiver or directly using a transceiverless link to an external integrated circuit (IC) supporting the same TLL protocol.

[Figure 22-8](#) highlights the high-speed USB host subsystem.

Figure 22-8. High-Speed USB Host Subsystem Highlight

usb-007

22.2.1.1 Main Features

The high-speed USB host subsystem includes the following features:

- **Multiport high-speed USB host controller:**
 - Complies with the USB 2.0 standard for high-speed (480 Mbps) functions
 - USB 2.0 low-speed (1.5M bit/s), full-speed (12M bit/s), and high-speed (480M bit/s) operations
 - Three downstream ports (3-port root hub)
 - Complies with EHCI (high-speed host controller)
 - Complies with OHCI (low-speed/full-speed host controller)
 - Supports suspend/resume and remote wakeup
 - Interface with USBTLL port A on all ports (UTMI+)
 - 8-bit datapath
 - 60-MHz synchronous (on-chip) interface
 - Interface with ULPI PHYs (transceivers) on all ports (only two mapped)
 - 12-pin/8-bit data single data rate (SDR) mode
 - 60-MHz clock input, provided by the host not the PHY (see TLL module below)

CAUTION

The HS USB host subsystem can only support the external charge pump of PHY (no support of internal charge pump for ULPI PHY)

- Hardware-driven save-and-restore of the suspended host hardware context
- Two interrupt lines
- USBTLL module
 - Three channels
 - Three ports (A, C, and D) by channel
- Port A: PHY-side UTMI+ port. Connects to the local link controller. The UTMI "local" port is used in all configurations, (that is, the entire channel can be seen as a protocol converted from that port to one of the other, "remote" ports).
 - Compliant with UTMI+ (USB 2.0 Transceiver Macrocell Interface) version 1.0
 - 8-data-bit, 60-MHz UTMI (HS/FS/LS-capable)
 - UTMI+ Level 3 extensions
 - Vcontrol/Vstatus (from UTMI)
 - Serial FS/LS "6-pin" mode
- Port C: PHY-side ULPI port. Connects to a remote (off-chip) ULPI link controller through I/O pads.
 - SDR and dual data rate (DDR) ULPI capable (resp 8/4-bit data width modes)
 - Supports optional 6-pin/3-pin serial modes
- Port D: Serial multimode port. Connects to either a serial link controller (TLL modes) or a serial PHY (PHY interface modes).
 - Supports 6-pin unidirectional, 4-pin bidirectional, 3-pin bidirectional, 2-pin bidirectional modes
 - All modes are supported for TLL or PHY interface configuration.
 - Supports sideband signals (pullup/down control, speed/suspend enable, etc)
- An interrupt line
- USB port signal pins interface supporting:
 - External USB transceivers
 - ULPI interface: 12-pin/8-bit data SDR version; ULPI clock provided by the device
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
 - TLL mode
 - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode, (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode) and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

Table 22-24. USB Connectivity Modes

USB Connectivity Modes	Port 1	Port 2	Port 3
ULPI interface	✓	✓	
Serial 6-pin transceiver interfaces	✓	✓	✓
ULPI TLL interfaces	✓	✓	✓
Serial 6-pin TLL interfaces	✓	✓	✓

NOTE: Only FS/LS USB transceivers can be connected to port 3; HS ULPI transceivers are not supported on port 3.

WARNING

The three channels when in ULPI mode are always ULPI clock providers, an input clock is not accepted.

22.2.2 High-Speed USB Host Subsystem Environment

The high-speed USB host controller provides two kinds of interfaces for connection:

- ULPI interfaces for high-speed data transactions (up to 480M bit/s)
- Serial interfaces (with the use of the USBTLL module) for full- and low-speed data transactions (up to 12M bit/s)

The high-speed USB host controller connects to either controllers (TLL modes) and/or transceivers. It supports the following configurations with the serial interfaces and ULPI interfaces:

- External USB transceiver configurations
 - ULPI interface: 12-pin/8-bit data SDR version
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode) and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL configurations
 - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

22.2.2.1 Standard USB Implementation: Transceiver Connection

From a logical point of view, a point-to-point USB connection is composed of several blocks, organized in protocol layers, and shown in [Figure 22-9](#).

Figure 22-9. USB Connection

The host system (USB master) and the peripheral system (USB slave) connected through the USB cable include a link or controller (link layer) and a PHY or transceiver (physical layer). Each system talks to its own controller, which talks to its own transceiver, which is connected to the opposite side (transceiver) through an assembly of connectors, receptacles, and cable.

22.2.2.2 TLL Connection

The TLL feature enables connection of the high-speed USB host subsystem to an external, onboard USB peripheral controller, without using USB transceivers or associated circuitry. When TLL is used, the following components are removed:

- Both USB transceivers
- The series resistors
- Pullup and pulldown resistors
- VBUS switching components
- USB connectors and cables, typically used between a USB host controller and the downstream USB peripheral controller

The TLL signaling system is not suitable for use across a cable. It is intended only for use when the device is used with an external USB integrated circuit (IC) that is on the same board.

When using the TLL, signals of the external USB IC pins, which typically connect to a USB transceiver, instead directly connect to the device pins. Signaling on these pins use CMOS levels. TLL logic can be used with external devices that support ULPI TLL interface and serial 6-pin TLL interface connectivity.

The TLL function in the device interprets the transmit control signals from the external USB IC and similar signals from the device USB host controller, and computes the equivalent USB differential-pair state. The computed differential-pair state is interpreted and the appropriate transceiver output signals are provided to the external USB IC and to the device USB host controller.

Figure 22-10 shows the device and how TLL can be compared to a typical USB implementation. The top portion of Figure 22-10 shows the a transceiver-based solution, and the bottom portion shows a transceiverless solution using TLL.

Figure 22-10. High-Speed USB Host Controller Connection-With and Without TLL

usb-009

NOTE: The USB bus lines (D+/D-) no longer appear in subsequent figures: They are emulated by the TLL.

22.2.2.3 ULPI Interfaces

The high-speed USB host subsystem supports the following configurations with the ULPI interfaces:

- External USB transceiver
 - ULPI interfaces: 12-pin/8-bit data SDR version
- TLL
 - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions

The high-speed USB host subsystem supports USB ports, which use the ULPI interface mode to connect to an off-chip high-speed ULPI transceiver (12-pin/8-bit data SDR mode) for high- and full-speed data transactions (up to 480M bit/s). Using the ULPI interfaces in 12-pin/8-bit data version, the device and the transceiver achieve the USB function. A mini A-B external receptacle allows the connection of an external device.

The device supports TLL logic interfaces on its ports in the ULPI TLL interface mode. TLL modes enable glueless interconnect to another USB device port without a costly transceiver.

Figure 22-11 and Figure 22-12 show typical applications using the high-speed USB host subsystem with the ULPI, and the ULPI TLL, respectively.

Figure 22-11. High-Speed USB Host Controller Typical Application System - ULPI Interfaces

usb-010

NOTE: ULPI interfaces: USBTLL is bypassed and high-speed USB host controller ports 1 and 2 are connected directly to external transceivers.

Figure 22-12. High-Speed USB Host Subsystem Typical Application System - ULPI TLL Interfaces

usb-032

NOTE: ULPI TLL interfaces: The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The current implementation of the ULPI includes a method for manual, software-controlled generation of PHY-side register accesses. This implies support of the following features:

- Access to vendor-specific or optional PHY-side registers
- Access to vendor ID, product ID, and scratch and debug registers

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY (transceiver) clock (SDR mode), whereas the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edges (DDR mode).

22.2.2.3.1 Transceiver Interface Configurations

The high-speed USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI interface mode.

NOTE: In the device, only the ULPI ports 1 and 2 of the high-speed USB host controller are mapped and can be connected directly to external transceivers.

Figure 22-13 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI interface mode.

Figure 22-13. ULPI Interfaces - 12-Pin/8-Bit Data SDR Version

usb-011

22.2.2.3.2 TLL Configurations

The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The high-speed USB host subsystem supports the 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions of the ULPI TLL interface mode.

Figure 22-14 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

ULPI (PHY) Interfaces and ULPI TLL Interfaces can not be used together: Either the ULPI (PHY) Interfaces or the ULPI TLL Interfaces are selected.

22.2.2.4 Serial Interfaces

The high-speed USB host subsystem supports the following configurations with the serial interfaces:

- External USB transceiver
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

Figure 22-17 shows a typical application using the high-speed USB host subsystem with the serial interfaces.

Figure 22-17. High-Speed USB Host Subsystem Typical Application System

usb-015

The high-speed USB host controller is coupled with the USBTLL module to compose the serial interface modes. The USBTLL module translates the parallel, synchronous UTMI+ (Level 3) protocol to a serial, asynchronous one. The benefit of the conversion is a simplified interface to the transceiver.

CAUTION

Only full- and low-speed data transactions are possible in serial mode. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

CAUTION

It is possible to change the polarity of the TXEN signal for each USB port using the following bits:

- CONTROL.[CONTROL_WKUP_CTRL\[2\]](#)
M_FSUSB3_TXEN_N_OUT_POLARITY_CTRL

Whether in TLL or transceiver configuration, the serial interface follows the same principles. It is limited to full/low speed, and that high speed requires a parallel interface.

22.2.2.4.1 Encoding in Serial Mode**22.2.2.4.1.1 Unidirectional**

When a USB transceiver is connected to the device and used in 6-pin unidirectional DAT/SE0 encoding mode, the encoding described in [Table 22-26](#) is used.

Table 22-26. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DAT/SE0 Signaling)

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description					
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.					
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D- when TXEN is low/high; ignored when TXEN is high/low (depending on the TXEN signal polarity; see CONTROL. CONTROL_WKUP_CTRL[2, 1 and/or 0] MM_FSUSBi_TXEN_N_OUT_POLARITY_CTRL bit).	TXEN	DAT	SE0	D+	D-
				0	0	0	0	1
				0	1	0	1	0
				0	X	1	0	0
				1	X	X	Undriven	Undriven
RCV	Input	Output	Output from transceiver differential receiver					
			D+		D-		RCV	
			0		0		X	
			0		1		0	
			1		0		1	
			1		1		X	
DP	Input	Output	Output from transceiver single-ended D+ signal receiver					
			D+			DP		
			0			0		
			1			1		
DM	Input	Output	Output from transceiver single-ended D- signal receiver					
			D-			DM		
			0			0		
			1			1		

When a USB transceiver is connected to the device and used in 6-pin unidirectional DP/DM encoding mode, the encoding described in [Table 22-27](#) is used.

Table 22-27. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling)

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description							
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.							
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D- when TXEN is low/high; ignored when TXEN is high/low (depending on the TXEN signal polarity; see the CONTROL. CONTROL_WKUP_CTRL [2, 1 and/or 0] MM_FFSUBI_TXEN_N_OUT_POLARITY_CTRL bit).							
			TXEN	DAT	SE0	D+	D-			
			0	0	1	0	1			
			0	1	0	1	0			
			0	0	0	0	0			
			1	X	X	Undriven	Undriven			
RCV	Input	Output	Output from transceiver differential receiver							
			D+	D-	RCV					
			0	0	X					
			0	1	0					
			1	0	1					
			1	1	X					
DP	Input	Output	Output from transceiver single-ended D+ signal receiver							
			D+	DP						
			0	0						
			1	1						
DM	Input	Output	Output from transceiver single-ended D- signal receiver							
			D-	DM						
			0	0						
			1	1						

22.2.2.4.1.2 Bidirectional

When a USB or USB OTG transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 encoding mode, the encoding described in [Table 22-28](#) is used.

Table 22-28. Signaling Between High-Speed USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description	
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.	

Table 22-28. Signaling Between High-Speed USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling (continued)

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description					
DAT and SE0	Output	Input	When TXEN is low/high (depending on the TXEN signal polarity; see the CONTROL. CONTROL_WKUP_CTRL [2, 1 and/or 0] MM_FSUSBi_TXEN_N_OUT_POLARITY_CTR bit), the device drives DAT and SE0 and the transceiver drives D+ and D- based on the values of DAT and SE0.					
			TXEN	DAT	SE0	D+	D-	
			0	0	0	0	1	
	Output	Input	1	0	1	0	0	
			X	1	0	0	0	
			TXEN	D+	D-	DAT	SE0	
				1	0	0	1	
				0	1	0	0	
				1	0	1	0	
				1	1	Undefined	0	

NOTE: The device does not support 3-wire bidirectional signaling using DP/DM signals.

When a USB or USB OTG transceiver is connected to the device and is used in 4-pin bidirectional DP/DM encoding mode, the encoding described in [Table 22-29](#) is used.

Table 22-29. Signaling Between High-Speed USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description		
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.		
DM	Output	Input	Value driven to or received from D-		
			TXEN	DM	D-
			0	0	0
			0	1	1
	Input	Output	TXEN	D-	DM
			1	0	0
			1	1	1
			Value driven to or received from D+		
			TXEN	DP	D+
DP	Output	Input	0	0	0
			0	1	1
	Input	Output	TXEN	D+	DP
			1	0	0
			1	1	1
RCV	Input	Output	Output from transceiver differential receiver		
			D+	D-	RCV
			0	0	X
			0	1	0
			1	0	1
			1	1	X

NOTE: The device does not support 4-pin bidirectional signaling using DAT/SEO signals.

22.2.2.4.2 Sideband Signals for Serial Modes

Serial interfaces only carry the USB data information. Sideband control and status (respectively, to/from the transceiver/TLL or to the bus lines themselves) require additional signals, which are usually implemented in a case-by-case, ad hoc way.

- Sideband control examples: FS/LS (slew rate control), transceiver suspend, connect (D+/D– pullup), pulldown enable, VBUS drive, etc.
- Sideband status example: VBUS level (VBUS valid, session valid, session end), etc.
- Sideband signal implementations: Dedicated lines (one per sideband information bit), serial bus + interrupt line with register-mapped control/status (I²C, UART, etc.)

Figure 22-18 and Figure 22-19 show system integration for sideband signals for two logically identical USB connections: One in transceiver configuration, and one in TLL configuration. Although the sideband (purple) arrows are all oriented from controller to transceiver in the two figures, the sideband information flow is bidirectional (that is, it flows from controller to transceiver [control] but also from transceiver to controller [status]).

Figure 22-18 shows the transceiver configuration, where each side connects the sideband signals to its own transceiver. On the device (containing the USBTLL module), the sideband is decoded/re-encoded. The sideband signals available at the device boundary (and the USBTLL module) are decoded from the standard UTMI+ interface.

- Sideband output signals from the USBTLL module (speed, suspend, puen, etc.)
- The software-driven VBUS reporting procedure is described in [Section 22.2.4.2.4.1.1, VBUS Management in Serial Transceiver Configurations](#).

Figure 22-18. Serial Interface Sideband Integration - Transceiver Configuration

usb-016

Figure 22-19 shows the TLL configuration, where both transceivers are actually emulated inside the USBTLL module.

- The transceiver of the local controller (left) is working with the sideband information to/from the UTMI+ port. This is internal to the USBTLL module.
- The transceiver of the remote controller (right) must communicate with its controller, located on another IC. This is done in two ways:
 - Sideband input signals at the TLL module boundary (tllpuen, tlldrvvbus, tlvbustvalid, etc.)

- The software-driven VBUS control procedure is described in [Section 22.2.4.2.4.2.2, VBUS Emulation for TLL Configurations](#)

Figure 22-19. Serial Interface Sideband Integration - TLL Configuration

22.2.2.4.3 Transceiver Interface Configurations

An external USB transceiver is required for each USB port used in the system. It converts between appropriate signaling for the high-speed USB host subsystem and appropriate signaling for the USB wire.

The serial interface mode of the high-speed USB host subsystem includes support for several types of USB transceivers. It provides signaling to up to three external USB transceivers.

Several types of external transceiver signaling are supported. Signaling between the high-speed USB subsystem in the serial-interface mode and the external USB transceiver for monitoring and controlling the differential USB signal can be done through a 6-, 4-, or 3-wire signaling interface, with two or more control signals provided either by additional signals or through an I²C link.

The following subsections describe the transceiver interface modes supported by the high-speed USB host subsystem in the serial interface mode. In each case, the subsystem is connected to external transceivers, on the other side of which are the actual USB lines (D+/D-).

22.2.2.4.3.1 Unidirectional Transceiver Interface Modes: 6-Pin

The 6-pin modes are the "natural" transceiver interface modes for the full-speed transceivers in the sense that they mirror the internal makeup of the transceivers.

Two encodings exist for TX: DAT/SE0 or DP/DM.

When a USB is connected to the device and used in 6-pin unidirectional DAT/SE0 signaling mode, the signaling described in [Table 22-26](#) is used.

[Figure 22-20](#) shows a USB port using DAT/SE0 encoding.

Figure 22-20. 6-Pin Unidirectional Using DAT/SE0 Signaling

x is the USB port number (1, 2 or 3)

usb-018

When a USB is connected to the device and used in 6-pin unidirectional DP/DM signaling mode, the signaling described in [Table 22-27](#) is used.

[Figure 22-21](#) shows a USB port using DP/DM encoding.

Figure 22-21. 6-Pin Unidirectional Using DP/DM Signaling

x is the USB port number (1, 2 or 3)

usb-019

22.2.2.4.3.2 Bidirectional Transceiver Interface Modes: 3-Pin, 4-Pin

The bidirectional transceiver interface modes are pin-count optimizations of the unidirectional modes. They take advantage of the fact that a USB port is either sending or receiving at any given time, but never both. The TX and RX paths of the unidirectional mode can be multiplexed on bidirectional lines. To prevent glitches at TX/RX turnaround, the same encoding is used for both directions (DAT/SE0 or DP/DM).

The signaling listed in [Table 22-28](#) is used when a USB transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 signaling mode.

NOTE: The device does not support 3-wire bidirectional signaling using DP/DM signals.

Figure 22-22 shows a USB port using DAT/SE0 encoding.

Figure 22-22. 3-Pin Bidirectional Using DAT/SE0 Signaling

x is the USB port number (1, 2 or 3)

usb-020

The signaling listed in [Table 22-29](#) is used when a USB transceiver is connected to the device and is used in 4-pin bidirectional DP/DM signaling mode.

NOTE: The device does not support 4-pin bidirectional signaling using DAT/SE0 signals.

Figure 22-23 shows a USB port using DP/DM encoding.

Figure 22-23. 4-Pin Bidirectional Using DP/DM Signaling

x is the USB port number (1, 2 or 3)

usb-021

22.2.2.4.4 TLL Configurations

The high-speed USB host subsystem supports unidirectional and bidirectional TLL logic interfaces on its ports. The TLL modes enable glueless interconnect to the USB device port of another device without needing a costly transceiver.

Serial interface modes are full- or low-speed only. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

22.2.2.4.4.1 Unidirectional TLL Modes

The 6-pin TLL configurations are mirror images of the 6-pin transceiver configurations presented above. The same signals are mapped on the same physical pins, but in the opposite directions.

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 22-24 shows an external device using DAT/SE0 encoding.

Figure 22-24. 6-Pin Unidirectional TLL Using DAT/SE0 Signaling

usb-022

Figure 22-25 shows an external device using DP/DM encoding.

Figure 22-25. 6-Pin Unidirectional TLL Using DP/DM Signaling

usb-023

22.2.2.4.4.2 Bidirectional TLL Modes

The 3-pin/4-pin TLL configurations are mirror images of the 3-pin/4-pin transceiver configurations presented above. The same signals are mapped on the same physical pins, but in the opposite directions (bidirectional lines remain bidirectional).

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 22-26 shows an external device using DAT/SE0 encoding.

Figure 22-26. 3-Pin Bidirectional TLL Using DAT/SE0 Signaling

usb-024

Figure 22-27 shows an external device using DP/DM encoding.

Figure 22-27. 4-Pin Bidirectional TLL Using DP/DM Signaling

usb-025

The 2-pin TLL configurations have unique specifications:

- They require pullups/pulldowns to operate, because the bidirectional lines are not driven at all times like the other serial transceiver interfaces described above. The connection of pull resistors depends on the speed of the controller.
- The module supports explicit 2-pin TLL modes, with either DAT/SE0 or DP/DM encoding.
- Non-TLL modes (that is, transceiver configuration mode) can be used to implement the 2-pin functionality, using a specific connectivity.

Figure 22-28 shows USB port using DP/DM encoding.

Figure 22-28. 2-Pin Bidirectional TLL Using DP/DM Encoding, With 4-Pin Bidirectional USB Device

22.2.3 High-Speed USB Host Subsystem Integration

This section describes the integration of the high-speed USB host subsystem.

The high-speed USB host controller is connected to the L3 interconnect master (initiator) and L4-Core interconnect slave (target) interfaces. The USBTLL module is connected to the L4-Core interconnect slave (target) interface. The L3 interconnect is used to generate data traffic within the device. The L4-Core interconnect is a configuration port for register setting.

Three interrupts, M_IRQ_[78:76], are connected to the system.

The system control module (SCM) offers complementary settings for USB port connectivity modes.

[Figure 22-30](#) highlights the high-speed USB host subsystem integration in the device.

Figure 22-30. High-Speed USB Subsystem Integration

usb-028

22.2.3.1 Reset, Clocking, and Power-Management Scheme

The high-speed USB host controller belongs to the USBHOST power domain. As part of the USBHOST power domain, it is sensible to the USBHOST_RST reset signal issued by the PRCM and to USBHOST power domain-related transitions. For further details about USBHOST power domain implementation and USBHOST_RST signal, see [Chapter 3, Power, Reset, and Clock Management](#).

The USBTLL module belongs to the CORE power domain. As part of the CORE power domain, it is sensible to the asynchronous USBTLL_RST reset signal issued by the PRCM and to CORE power domain-related transitions. For further details about CORE power domain implementation and USBTLL_RST signal, see [Chapter 3, Power, Reset, and Clock Management](#).

22.2.3.1.1 High-Speed USB Host Subsystem Resets

[Table 22-33](#) lists and describes all the high-speed USB host subsystem resets:

Table 22-33. High-Speed USB Host Subsystem Reset Description

Type	Name	Source	Polarity	Description
Software	USBHOST. UHH_SYSCONF1 G[1] SOFTRESET bit	High-speed USB host controller internal software reset	Active high	Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.
Software	USBHOST. USBTLL_SYSSCO NFIG[1] SOFTRESET bit	USBTLL module internal software reset	Active high	Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.
Hardware	USBHOST_RESET	PRCM USBHOST_RST signal	Active low	The USBHOST_RST signal resets the module. The hardware reset signal has a global reset action on the high-speed USB host controller (see Chapter 3, Power, Reset, and Clock Management).
Hardware	USBTLL_RESET	PRCM USBTLL_RST signal	Active low	The USBTLL_RST signal resets asynchronously the module. The hardware reset signal has a global reset action on the USBTLL module (see Chapter 3, Power, Reset, and Clock Management).

22.2.3.1.1.1 Hardware Resets

The high-speed USB host controller is attached to the USBHOST power domain: The USBHOST_RST signal resets the module. The USBTLL module is attached to the CORE power domain: The USBTLL_RST signal resets asynchronously the module (see [Chapter 3, Power, Reset, and Clock Management](#)). The hardware reset signal has a global reset action on the modules.

22.2.3.1.1.2 Software Resets

The high-speed USB host controller and the USBTLL module have their own software-reset functionality through the USBHOST.[UHH_SYSCONFIG](#)[1] SOFTRESET bit (0: Normal mode; 1: Module is reset) for the high-speed USB host controller, and through the USBHOST.[USBTLL_SYSCONFIG](#)[1] SOFTRESET bit (0: Normal mode; 1: Module is reset) for the USBTLL module.

Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.

22.2.3.1.2 High-Speed USB Host Subsystem Clocks

The high-speed USB host controller operates from four clock domains:

- USBHOST_FCLK1 is a high-speed USB host controller functional clock. It is used to clock the OHCI and EHCI controller internal logic of the high-speed USB host controller. Its source is the PRCM USBHOST_48M_FCLK output clock. USBHOST_FCLK1 is controlled by the PRCM.PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1 bit (0: Disabled; 1: Enabled).
- USBHOST_FCLK2 is a high-speed USB host controller functional clock. It is used to clock EHCI controller internal logic of the high-speed USB host controller. Its source is the PRCM USBHOST_120M_FCLK output clock. USBHOST_FCLK2 is controlled by the PRCM.PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2 bit (0: Disabled; 1: Enabled).
- USBHOST_MICLK is the high-speed USB host controller L3 master interface clock. It is used to synchronize the high-speed USB host controller L3 port to L3 interconnect. All accesses from the interconnect are synchronous to USBHOST_MICLK. Its source is the PRCM USBHOST_L3_ICLK output clock. USBHOST_MICLK is controlled by the PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST bit (0: Disabled; 1: Enabled) and the PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit (enables/disables automatic control of the interface clock).
- USBHOST_SICLK is a high-speed USB host controller L4 slave interface clock. It is used to synchronize the high-speed USB host controller L4 port to L4 interconnect. All accesses from the interconnect are synchronous to USBHOST_SICLK. Its source is the PRCM USBHOST_L4_ICLK output clock.

The USBTLL module operates from two clock domains:

- USBTLL_FCLK is the USBTLL module functional clock. It is used to clock the USBTLL module internal logic. Its source is the PRCM CORE_120M_FCLK output clock. UBTLL_FCLK is controlled by the PRCM.CM_FCLKEN3_CORE[2] EN_USBTLL bit (0: Disabled; 1: Enabled).
- USBTLL_ICLK is the USBTLL module interface clock. It is used to synchronize USBTLL module L4 port to L4 interconnect. All accesses from the interconnect are synchronous to USBTLL_ICLK. Its source is the PRCM CORE_L4_ICLK output clock. USBTLL_ICLK is controlled by the PRCM.CM_ICLKEN3_CORE[2] EN_USBTLL bit (0: Disabled; 1: Enabled) and the PRCM.CM_AUTOIDLE3_CORE[2] AUTO_USBTLL bit (enables/disables automatic control of the interface clock).

Table 22-34 summarizes the high-speed USB host subsystem clocks.

Table 22-34. High-Speed USB Host Subsystem Clocks

Attributes	Frequency	Name	Module	Mapping	Comments
Functional clock	48 MHz	USBHOST_FCLK1	High-speed USB Host controller	USBHOST_48M_FCLK	Source is PRCM module
Functional clock	120 MHz	USBHOST_FCLK2	High-speed USB Host controller	USBHOST_120M_FCLK	Source is PRCM module
L3 master interface clock	Depending on PRCM register settings	USBHOST_MICLK	High-speed USB Host controller	USBHOST_L3_ICLK	Source is PRCM module
L4 slave interface clock	Depending on PRCM register settings	USBHOST_SICLK	High-speed USB Host controller	USBHOST_L4_ICLK	Source is PRCM module
Functional clock	120 MHz	USBTLL_FCLK	USBTLL	CORE_120M_FCLK	Source is PRCM module
L4 interface clock	Depending on PRCM register settings	USBTLL_ICLK	USBTLL	CORE_L4_ICLK	Source is PRCM module

22.2.3.1.2.1 L3 Master Interface Clock

The L3 master interface clock (USBHOST_L3_ICLK) is used only by the high-speed USB host controller (USBHOST_MICLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN_USBHOST[0]:

0: Disabled
1: Enabled

and PRCM.CM_AUTOIDLE_USBHOST[0] (enables/disables automatic control of the interface clock)-see Table 22-35.

Table 22-35. High-Speed USB Controller L3 Master Interface Clock

PRCM.CM_AUTOIDLE_USBHOST[0]	PRCM.CM_ICLKEN_USBHOST[0]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

CAUTION

The L3 master interface clock should not be below 30 MHz, ULPI clock divided by 2 (this can occur during DPLL3 relocking).

22.2.3.1.2.2 L4 Slave Interface Clock

The L4 slave interface clock (USBHOST_L4_ICLK) is used only by the high-speed USB host controller (USBHOST_SCLK) in the subsystem, and comes from the PRCM module.

22.2.3.1.2.3 L4 Interface Clock

The L4 interface clock (CORE_L4_ICLK) is used only by the USTLL module (USTLL_ICLK) in the subsystem, and comes from the PRCM module.

This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN3_CORE[2]:

- 0: Disabled
- 1: Enabled

and PRCM.CM_AUTOIDLE3_CORE[2] (enables/disables automatic control of the interface clock), see Table 22-36.

Table 22-36. USTLL Module Interface Clock

PRCM.CM_AUTOIDLE3_CORE[2]	PRCM.CM_ICLKEN3_CORE[2]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

22.2.3.1.2.4 Functional Clocks

Two functional clocks are provided by the PRCM module to the high-speed USB host controller: USBHOST_FLCK1 running at 48 MHz (USBHOST_48M_FCLK) and USBHOST_FLCK2 running at 120 MHz (USBHOST_120M_FCLK).

The USBHOST_FLCK1 functional clock is controlled by the PRCM register bit PRCM.CM_FCLKEN_USBHOST[0]:

- 0: Disabled
- 1: Enabled

The USBHOST_FCLK2 functional clock is controlled by the PRCM register bit PRCM.CM_FCLKEN_USBHOST[1]:

- 0: Disabled
- 1: Enabled

The CORE_120M_FCLK functional clock is used only by the USBTLL module (USBTLL_FCLK) in the subsystem, and comes from the PRCM module.

This clock is controlled by the PRCM register bit

PRCM.CM_FCLKEN3_CORE[2]:

- 0: Disabled
- 1: Enabled

22.2.3.1.3 Power-Management Scheme

22.2.3.1.3.1 High-Speed USB Host Controller Power-Management Scheme

22.2.3.1.3.1.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB host controller power management is applied only to the interface clock domain.

The high-speed USB host controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB host controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB host controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

Table 22-37 details the high-speed USB host controller module PRCM clock control bits.

Table 22-37. High-Speed USB Host Controller PRCM Clock Control Bits

Module Clock	Associated PRCM Clock Output	Enabled Bit	Autoidle Bit
USBHOST_FCLK1	USBHOST_48M_FCLK	PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1 bit	N/A
USBHOST_FCLK2	USBHOST_120M_FCLK	PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2 bit	N/A
USBHOST_MCLK	USBHOST_L3_ICLK	PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST bit	PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit

NOTE:

- The PRCM USBHOST_48M_FCLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM USBHOST_120M_FCLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM USBHOST_L3_ICLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit is used to link/unlink the high-speed USB host controller from USBHOST_L3_ICLK-related clock domain transitions.
- For further details about source clocks gating and domain transitions, see [Chapter 3, Power, Reset, and Clock Management](#).

22.2.3.1.3.1.2 L3 Master Interface Power Management

The high-speed USB host controller can go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB host controller has a MSTANDBY/WAIT handshake mechanism with the PRCM module (see [Figure 22-30](#)).

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when there is no USB activity and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The whole module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module go to standby mode based on the USBHOST.UHH_SYSConfig[13:12] MIDLEMODE field.

Table 22-38. High-Speed USB Host Controller MIDLEMODE Settings

MIDLEMODE Value	Selected Mode	Description
0x0	Force-standby	The high-speed USB host controller enters standby mode unconditionally (MSTANDBY is asserted unconditionally).
0x1	No-standby	The high-speed USB host controller never enters standby mode (MSTANDBY is never asserted).
0x2	Smart-standby	The high-speed USB host controller is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

22.2.3.1.3.1.3 L4 Slave Interface Power Management

At PRCM level, when all the conditions to shut off the high-speed USB host controller output clocks are met (see [Chapter 3, Power, Reset, and Clock Management](#) for details), the PRCM module automatically launches a hardware handshake protocol to ensure the high-speed USB host controller is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the high-speed USB host controller. Although this handshake is completely hardware and out of any software control, the way in which the high-speed USB host controller acknowledges the PRCM IDLE request is configurable through the USBHOST.UHH_SYSConfig[4:3] SIDLEMODE bit field. [Table 22-39](#) details SIDLEMODE settings and the related acknowledgment modes.

Table 22-39. High-Speed USB Host Controller SIDLEMODE Settings

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The high-speed USB host controller acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. Because such a mode does not prevent any loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The high-speed USB host controller never acknowledges any IDLE request from the PRCM. This mode is safe from a module point of view as it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The high-speed USB host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the high-speed USB host controller also offers an additional granularity on its interface clock gating. The USBHOST.UHH_SYSConfig[9:8] CLOCKACTIVITY bit is used to control the interface clock internal gating while module is idle. [Table 22-40](#) details the CLOCKACTIVITY settings.

Table 22-40. High-Speed USB Host Controller CLOCKACTIVITY Settings

CLOCKACTIVITY Value	Interface Clock Effect	Description
0	OFF	Interface clock is considered for generating the acknowledgment. This setting also means the interface clock is shut down upon PRCM IDLE request.
1	ON	Interface clock is not shut down upon PRCM IDLE request. The high-speed USB host controller can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clock.

CAUTION

The PRCM does not have any hardware means to read CLOCKACTIVITY settings. Software ensures a consistent programming between the high-speed USB host controller CLOCKACTIVITY and PRCM interface clock control bit. Indeed, if the USBTLL module is disabled in the PRCM.CM_ICLKEN_USBHOST register while CLOCKACTIVITY is set to 1, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated to the USBTLL module interface clock. This may lead to unpredictable behaviors.

22.2.3.1.3.2 USBTLL Module Device Power-Management Scheme

From a global system power-management perspective, when one or both of the USBTLL module clocks are no longer required, the USBTLL module can be deactivated at PRCM level in the corresponding registers.

[Table 22-41](#) details the USBTLL module PRCM clock control bits.

Table 22-41. USBTLL Module PRCM Clock Control Bits

Module Clock	Associated PRCM Clock Output	Enabled Bit	Autoidle Bit
USBTLL_FCLK	CORE_120M_FCLK	PRCM.CM_FCLKEN3_CORE[2] EN_USBTLL bit	N/A
USBTLL_ICLK	CORE_L4_ICLK	PRCM.CM_ICLKEN3_CORE[2] EN_USBTLL bit	PRCM.CM_AUTOIDLE3_CORE [2] AUTO_USBTLL bit

NOTE:

- The PRCM CORE_120M_CLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the USBTLL module is a necessary but not sufficient condition.
- The PRCM CORE_L4_ICLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the USBTLL module is a necessary but not sufficient condition.
- The PRCM.CM_AUTOIDLE3_CORE[2] AUTO_USBPLL bit is used to link/unlink the USBTLL module from CORE_L4_ICLK-related clock domain transitions.
- For further details about source clocks gating and domain transitions, see [Chapter 3, Power, Reset, and Clock Management](#).

At PRCM level, when all the conditions to shut off the USBTLL_FCLK or USBTLL_ICLK output clocks are met (see [Chapter 3, Power, Reset, and Clock Management](#) for details), the PRCM module automatically launches a hardware handshake protocol to ensure the USBTLL module is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the USBTLL module. Although this handshake is completely hardware and out of any software control, the way in which the USBTLL module acknowledges the PRCM IDLE request is configurable through the USBHOST.USBTLL_SYSConfig[4:3] SIDLEMODE bit field. [Table 22-42](#) details SIDLEMODE settings and the related acknowledgment modes.

Table 22-42. USBTLL Module SIDLEMODE Settings

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The USBTLL module acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. Because such a mode does not prevent any loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The USBTLL module never acknowledges any IDLE request from the PRCM. This mode is safe from a module point of view as it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The USBTLL module acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the USBTLL module also offers an additional granularity on USBTLL_ICLK gating. The USBHOST.USBTLL_SYSConfig[9:8] CLOCKACTIVITY bit is used to control the USBTLL_ICLK clock internal gating while the module is idle. [Table 22-43](#) details the CLOCKACTIVITY settings.

Table 22-43. USBTLL Module CLOCKACTIVITY Settings

CLOCKACTIVIT Y Value	USBPLL_ICLK Effect	Description
0	OFF	USBPLL_ICLK is considered for generating the acknowledgment. This setting also means USBPLL_ICLK is shut down upon PRCM IDLE request.
1	ON	USBPLL_ICLK is not shut down upon PRCM IDLE request. The USBPLL module can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clock.

CAUTION

The PRCM does not have any hardware means to read CLOCKACTIVITY settings. Software ensures a consistent programming between the USBTLL module CLOCKACTIVITY and PRCM USBTLL_ICLK control bit. Indeed, if the USBTLL module is disabled in the PRCM.CM_ICLKEN3_CORE register while CLOCKACTIVITY is set to 1, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated to the USBTLL module interface clock. This may lead to unpredictable behaviors.

22.2.3.2 Hardware Requests**22.2.3.2.1 Interrupt Requests**

Table 22-44 lists the interrupt lines that are driven out from the high-speed USB host controller to the microprocessor unit (MPU) subsystem interrupt controller (INTC).

Table 22-44. High-Speed USB Host Subsystem Interrupts

Name	Mapping	Comments
HS USB OHCI Host Controller Interrupt		
OHCI_IRQ	M_IRQ_76	Destination is MPU subsystem interrupt controller
HS USB EHCI Host Controller Interrupt		
EHCI_IRQ	M_IRQ_77	Destination is MPU subsystem interrupt controller
USBTLL Module Interrupt		
TLL_IRQ	M_IRQ_78	Destination is MPU subsystem interrupt controller

22.2.3.2.2 IDLE Handshake Protocol

The PRCM handles an IDLE handshake protocol for the high-speed USB host controller and the USBTLL module. The IDLE handshake protocol allows the PRCM requiring the high-speed USB host controller to enter idle mode. The module acknowledges when it is ready.

22.2.3.2.3 MSTANDBY Handshake Protocol

The PRCM module handles an MSTANDBY handshake protocol for the high-speed USB host controller, which initiates the MSTANDBY handshake to inform the PRCM module when it enters standby mode and does not generate traffic on interconnect.

22.2.3.2.4 Wake-Up Request

Wake-up request signal USBHOST_SWAKEUP is generated by the high-speed USB host controller to the PRCM module. Wake-up request signal USBTLL_SWAKEUP is generated by the USBTLL module to the PRCM module.

22.2.4 High-Speed USB Host Subsystem Functional Description

This section describes the functionality of the high-speed USB host subsystem by describing the high-speed USB host controller and the USBTLL module.

22.2.4.1 High-Speed USB Host Controller Functionality

The full details of the standard OHCI and EHCI host controller APIs (implemented by the current module) are not repeated here. For more information, see the following public specifications:

- *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*
- *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*

22.2.4.1.1 High-Speed USB Host Controller Architecture

Figure 22-31 shows an overview of the high-speed USB host controller internal architecture: It contains two independent, 3-port host controllers that operate in parallel: EHCI and OHCI. Each of the three external ports is owned by exactly one of the controllers at any point in time. Each port can work in several modes:

- When the port is owned by the OHCI (full-speed) host controller, the serial 6-pin interface mode is used.
- When the port is owned by the EHCI (high-speed) host controller, either the ULPI or the UTMI modes are used.

The L4-Core interconnect is used to configure the two controllers, as well as a general, TI-specific register bank. The L3 interconnect merges and arbitrates between the transactions generated by the controller respective DMA engines.

Figure 22-31. High-Speed USB Host Controller Architecture

usb-029

22.2.4.1.2 OHCI Implementation Specifications

Some features of the OHCI API are optional and/or implementation-specific. The choices made in the current implementation, the high-speed USB host controller, are described below, and are reflected in the register descriptions (see [Section 22.2.6.4.3, OHCI Registers](#)). For all standard features, see the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*.

- **USBHOST.HCFMINTERVAL[30:16]** FSMPS field (FullSpeedMaxPacketSize) = 0x0000: Host will stop scheduling new packets 0 bit times before the end of the frame (that is, there is no scheduling overrun protection by default). To be updated by the software driver.
- **USBHOST.HCRHDESCRIPTORA[7:0]** NDP field (NumberDownstreamPorts) = 0x03 = 3 ports.
- **USBHOST.HCRHDESCRIPTORA[9]** NPS bit (NoPowerSwitching) = 0: Ports are power-switched by default.
- **USBHOST.HCRHDESCRIPTORA[8]** PSM bit (PowerSwitchingMode) = 1: Per-port power switching is supported, although PPCM default setup has all ports controlled globally (default must be = OCPM).
- **USBHOST.HCRHDESCRIPTORA[31:24]** POTPG field (PowerOnToPowerGood) = 0x0A = 10: Power

rampup time is $10 \times 2 \text{ ms} = 20 \text{ ms}$.

- **USBHOST.HCRHDESCRIPTORB[15:0]** DR field (DeviceRemovable) = 0x0000: By default, no nonremovable devices (that is, devices attached to any of the ports) are removable.
- **USBHOST.HCRHDESCRIPTORB[31:16]** PPCM field (PortPowerControlMask) = 0x0000: By default, all ports are affected only by global power control.

22.2.4.1.3 UTMI Ports

The high-speed USB host controller supports N "downstream" ports, numbered from 1 through N. (In USB terminology, port 0 is necessarily an "upstream" port, and because the host is on "top" of the USB topological tree it has none). In the current implementation N = 3 (that is, available ports are 1, 2, 3).

The high-speed USB host controller is configured to be either in UTMI or in ULPI mode (see each port configuration with the **USBHOST.UHH_HOSTCONFIG[12]** P3_ULPI_BYPASS, **USBHOST.UHH_HOSTCONFIG[11]** P2_ULPI_BYPASS, and **USBHOST.UHH_HOSTCONFIG[0]** P1_ULPI_BYPASS bits).

In UTMI mode (see *USB 2.0 Transceiver Macrocell Interface specification Release 1.05*), all ports are in UTMI mode (that is, each port has its UTMI signal set broadcast the "outgoing" packets - from the host to the peripherals) and gather the "incoming" ones (that is, from the addressed peripheral to the host). ULPI signal sets are undefined/don't care on all ports.

In the device, the UTMI ports connect to the USBTLL module. The UTMI ports between the high-speed USB host controller and the USBTLL module are on-chip and remain invisible.

22.2.4.1.4 ULPI Ports

The high-speed USB host controller supports N "downstream" ports, numbered from 1 through N. (In USB terminology, port 0 is necessarily an "upstream" port, and because the host is on "top" of the USB topological tree it has none). In the current implementation N = 3 (that is, available ports are 1, 2, 3).

The high-speed USB host controller is configured to be either in UTMI or in ULPI mode (see each port configuration with the **USBHOST.UHH_HOSTCONFIG[12]** P3_ULPI_BYPASS, **USBHOST.UHH_HOSTCONFIG[11]** P2_ULPI_BYPASS, and **USBHOST.UHH_HOSTCONFIG[0]** P1_ULPI_BYPASS bits).

In ULPI mode , all ports are in ULPI mode (that is, each port has its ULPI signal set broadcast the "outgoing" packets - from the host to the peripherals) and gather the "incoming" ones (that is, from the addressed peripheral to the host). UTMI signal sets are undefined/don't care on all ports.

When in ULPI mode, the high-speed USB host controller is in charge of generating the (nominally 60-MHz) clock to the transceiver on the ULPI interface. This is called ULPI "input" clocking mode, because the ULPI protocol is transceiver-centric. The opposite mode, "output mode" (that is, the host receives the ULPI clock from the transceiver), is not supported and there is consequently no ULPI clock input.

In the device, the ULPI ports can only be connected directly to external transceivers. The USBTLL module is bypassed. USB traffic can be monitored directly on the USB lines.

22.2.4.1.5 Port Status

The USB port status is given through the **USBHOST.UHH_HOSTCONFIG[10:8]** bit field. The default value of the following bits is 1:

- **USBHOST.UHH_HOSTCONFIG[8]** P1_CONNECT_STATUS
- **USBHOST.UHH_HOSTCONFIG[9]** P2_CONNECT_STATUS
- **USBHOST.UHH_HOSTCONFIG[10]** P3_CONNECT_STATUS

CAUTION

These bits show the port status as connected after power on even though no USB device is connected. The USB host controller has operational status registers (for example, `USBHOST.HCRHPORTSTATUS_1` for OHCI port 1) that indicate the correct port connect status. The USB driver software must read these status bits and check whether or not a port is connected. If the port is not connected, the USB driver software must reprogram the `USBHOST.UHH_HOSTCONFIG` bits to indicate the correct port connect status.

22.2.4.1.6 Save and Restore

The save-and-restore (SAR) mechanism can extract the hardware context of the high-speed USB host controller (after all USB activity has been suspended) before switching off (=save), save it to an external always-on memory, and reinject it later after the module has been switched on again and reset (=restore) seamlessly for the USB. Part of that context is composed of the register fields described in the current chapter. The rest of the context is composed of the "buried" flip-flops and memories (not accessible by software) like finite state-machine (FSM) states, buffer contents, and miscellaneous random logic bits.

The `PRCM.PM_PWSTCTRL_USBHOSTE[4]` `SAVEANDRESTORE` bit enables the SAR mechanism for the high-speed USB host controller (see [Chapter 3, Power, Reset, and Clock Management](#)). When set, the PRCM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

22.2.4.1.7 L3 Burst Control

To avoid buffer underflow, bursts must be enabled by writing 0x7 in the `USBHOST.UHH_HOSTCONFIG[4:2]` bit field and by setting the `USBHOST.UHH_HOSTCONFIG[5]` `ENA_INCR_ALIGN` bit to 1.

22.2.4.2 USBTLL Module Functionality

The USBTLL module implements a TLL compatible with a number of USB standard interface protocols. Once the interface protocol has been selected during an initial configuration phase, USB operation should take place seamlessly (that is, as if actual transceivers were present). To ensure maximum compatibility, as many features as possible have been included, as described in the rest of this document. The basic principle is that all the software "handles" should be available and behave in a proper way, even if there is no actual functionality underneath.

The USBTLL module is integrated with the high-speed USB host controller in the device. The transceiver interfaces (UTMI ports) between the high-speed USB host controller and the USBTLL module are on-chip and remain invisible. The other transceiver interfaces go off-chip, where they can be connected to the other controllers (for example, peripherals) on another IC.

22.2.4.2.1 Channels and Ports

Following the same convention than UTMI and ULPI, the current specification is consistently PHY-centric (that is, directions are always given with respect to the transceiver emulated here by the TLL), and not with respect to the link controller: An "input" goes from the link controller to the TLL (transceiver emulator) (that is, it is an input for the USBTLL module. Reciprocally, an "output" goes from TLL (transceiver) to the link controller (that is, it is an output for the USBTLL module).

By convention, the local link controller is the controller integrated on the same IC as the USBTLL module: This is the high-speed USB host controller in the device. The remote link controller is the other controller, located off-chip (that is, on another IC). One controller is always the USB host, the other the USB peripheral, and they communicate through the USBTLL module.

A channel is defined as an independent USB path through the USBTLL module, which always converts the UTMI+ transceiver interface protocol coming from the local link controller (the high-speed USB host controller in the device). The number of channels of the USBTLL module is three in the device.

A USB port is a set of I/O signals that carry the data and control information from/to a USB line. Several port formats exist, with different capabilities. A channel has three ports. If the channel is active, two ports are active at a time, depending on the channel configuration. The mode remains static throughout USB operation. [Table 22-45](#) summarizes the ports features.

22.2.4.2.2 Channel Architecture

[Figure 22-32](#) shows the architecture of a single channel (of three) of the USBTLL module, and its integration in a USB system. The ports are indicated by the circled letters (A, C, and D). See the following descriptions:

- Full arrows represent parallel, synchronous, high-speed-capable interfaces.
- Line arrows represent serial, combinatorial, full-speed/low-speed-only interfaces.
- Arrows always point toward the PHY layer (actual transceiver or TLL, in yellow), away from the link controller.
- The arrow marked ULPI* represents the entire ULPI protocol (synchronous or not) except the 3-/6-pin serial TLL modes which are reoriented toward the serial TLL block.
- The USBTLL module cannot interface with a ULPI transceiver. This functionality is provided by the high-speed USB host controller.
- Top-level multiplexing is shown only for information. It is static and does not add functionality. The figure shows ULPI and serial ports implemented on different I/O pads for clarity, but a real implementation would typically reuse the same pads, because the interfaces cannot be active simultaneously

Figure 22-32. USBTLL Channel

[Table 22-45](#) summarizes the properties of each port.

Table 22-45. USBTLL Channel USB Ports

USBTLL Port	Port Description	Connect to Controller	Connect to Transceiver	Serial (Full-Speed/ Low-Speed only)	Parallel (High-Speed/ Full-Speed/Low-Speed)
A	PHY-side UTMI+	UTMI+ (L3)	No	6-pin	60-MHz UTMI
C	PHY-side ULPI	ULPI TLL	No	6-pin	60-MHz UTMI
D	Multimode Serial	6-/4-/3-/2-pin TLL	6-/4-/3-/2-pin	6-/4-/3-/2-pin TLL	No

22.2.4.2.2.1 Port A: PHY-side UTMI+ Port

Connects to the high-speed USB host controller in the device. The UTMI "local" port is used in all configurations (that is, the entire channel can be seen as a protocol converted from that port to one of the remote ports C or D).

- Compliant with UTMI+ version 1.0
- 8-data-bit, 60 MHz UTMI (HS/FS/LS-capable)
- UTMI+ Level 3 extensions
- Vcontrol/Vstatus (from UTMI)
- Serial FS/LS "6-pin" mode

22.2.4.2.2.2 Port C: PHY-Side ULPI Port

Connects to a remote (off-chip) ULPI controller through I/O pads.

- Compliant with ULPI version 1.1
- SDR and DDR ULPI capable (respectively, 8-bit/4-bit data width modes)
- Supports optional 6-pin/3-pin serial modes

22.2.4.2.2.3 Port D: Serial Multimode Port

Connects to either a serial controller (TLL modes) or a serial transceiver (transceiver interface modes).

- Supports 6-pin (TX: DAT/SE0 or TX: DP/DM) unidirectional, 4-pin bidirectional, 3-pin bidirectional, 2-pin bidirectional modes
- All modes are supported for TLL or transceiver interface configuration.
- Supports sideband signals (pullup/down control, speed/suspend enable, etc.)

22.2.4.2.3 Channel Configuration

A channel configuration is a set of software settings that specifies the connection of two of the channel ports through the USBTLL module. USB data and control injected on one side (or port) comes out on the other side (or port) after a certain amount of processing, depending on the mode. [Table 22-46](#), lists the modes.

All configurations connect the PHY UTMI port (attached to the high-speed USB host controller) to one of the other two ports (attached to a variety of transceivers or controllers on the pads side).

[Table 22-46](#) describes the available modes and the software settings required for each. Channel i has the following settings:

- CHANMODE: `USBHOST.TLL_CHANNEL_CONF_i[2:1]` CHANMODE field
- FSLSMODE: `USBHOST.TLL_CHANNEL_CONF_i[27:24]` FSLSMODE field
- FSLSSERIALMODE_3PIN/6PIN: Either the ULPI PHY-side `USBHOST.ULPI_INTERFACE_CTRL_i[1]` FSLSSERIALMODE_3PIN bit or the `USBHOST.ULPI_INTERFACE_CTRL_i[0]` FSLSSERIALMODE_6PIN bit (only one can be set to 1 at a time)

Table 22-46. USBTLL Channel Configuration

Configuration	Mode	CHAN MODE	FSLSMODE	Other Settings	Ports	Speed	Remote Port Connection
2	ULPI synchronou s TLL	0	N/A	FSLSSERIALMODE_3PIN/6PIN = 0	A-C	HFL	ULPI link (peripheral controller)
4	Serial UTMI to serial ULPI TLL	0	N/A	FSLSSERIALMODE_3PIN/6PIN = 1	A-C	FL	ULPI link (peripheral controller) supporting 3-/6-pin mode
6	Serial UTMI to serial TLL	1	0x4 to 0x7; - 0xA to 0xB		A-D	FL	Serial link (2-/3-/4-/6-pin)

Table 22-46. USBTLL Channel Configuration (continued)

Configuration	Mode	CHAN MODE	FSLSMODE	Other Settings	Ports	Speed	Remote Port Connection
6	Serial UTMII to serial PHY	1	0x0 to 0x3	-	A-D	FL	Serial transceiver (2-/3-/4-/6-pin)

Figure 22-33. Per-Configuration Datapath Through USBTLL

usb-031

22.2.4.2.4 VBUS Management and Emulations

In transceiver configurations, an actual USB cable is present, including an actual 5 V VBUS supply line. On the other hand, in TLL configurations, the physical USB lines are emulated and have no physical existence. This is especially true for the VBUS line, which distributes the 5-V power provided by the default host (or A-device) to the entire bus. VBUS is also used for signaling purposes, and those features must be emulated:

- A peripheral detects the presence of a host by detecting the presence of VBUS.
- USB OTG defines an elaborate voltage-sensing scheme to dynamically switch on and off VBUS (start and stop sessions). In the context of TLL, this brings no power saving compared to simple suspend.
- In particular, USB OTG uses VBUS as a wake-up source (VBUS-pulsing SRP) for the default peripheral (or B-device).

For more information on how sideband controls are integrated, see [Figure 22-18](#) and [Figure 22-19](#) and the related explanations.

22.2.4.2.4.1 VBUS Control and Status for Transceiver (Non-TLL) Configurations

In non-TLL modes, VBUS exists, and the problem is to propagate control and status to/from the actual VBUS manager IC (typically the transceiver itself).

Only serial transceiver configurations are concerned in the case of the high-speed USB host subsystem in the device.

22.2.4.2.4.1.1 VBUS Management in Serial Transceiver Configurations

VBUS management is not standardized in transceiver configurations. The chosen implementation is described below. See also [Figure 22-18](#).

- VBUS control required for host and OTG operation (VBUS drive, VBUS pullup "charge", VBUS pulldown "discharge") is assumed to be taken care of separately from the USBTLL module (that is, by software and straight to the power IC, which can be the transceiver itself, especially in OTG cases).
- VBUS status must be sampled by the appropriate hardware (again, most of the time the transceiver itself) and reported by software to the USBTLL module, using the USBHOST.TLL_CHANNEL_CONF_i.DRVVBUS and CHRGVBUS bits, as indicated in [Table 22-47](#).

[Table 22-47](#) lists the values to write to the USBHOST.TLL_CHANNEL_CONF_i register depending on the VBUS status observed by the transceiver on the actual VBUS line. The same register fields are also used in TLL configuration, and have been named according to that second configuration. In transceiver configurations the fields actual signification is:

- DRVVBUS: Set to 1 to report a VBUS level greater than *VBUS valid*.
- CHRGVBUS: Set to 1 to report a VBUS level greater than *Session valid*

Table 22-47. VBUS Level Software Reporting for Serial Transceiver Configuration

VBUS Status	USBHOST.TLL_CHANNEL_CONF_i[16] DRVVBUS Bit	USBHOST.TLL_CHANNEL_CONF_i[15] CHRGVBUS Bit
VBUS valid	1	1
Session valid (A/B)	0	1
Session not valid	0	0
Session end	0	0

22.2.4.2.4.2 VBUS Emulation for TLL Configurations

The TLL VBUS emulation sums up all actions on the VBUS line, obtains a voltage level, reported in the VBUS status bits following the protocol. The level depends on the immediate VBUS actions and has no memory of previous levels, whereas a real VBUS line behaves like an RC circuit and takes time to charge and discharge. This causes the following differences:

- The TLL level always jumps abruptly from session valid to session end (and back) with no transient time in between (where session is neither valid nor ended) as in real life.

- The Charge feature is used for VBUS-pulsing SRP, and is enabled long enough to go over the Session valid threshold, but without reaching VBUS valid. In the TLL the transition to Session valid is immediate, and VBUS valid is never reached even if the Charge is intentionally kept active.
- The Discharge feature is used in real life to accelerate the voltage drop of an undriven VBUS towards the session-end level. For TLL, this is therefore useless (although the UTMI input/ULPI register bit do exist, for compatibility), and always a "don't care"

22.2.4.2.4.2.1 VBUS Emulation in ULPI TLL Modes

Table 22-48 summarizes the VBUS emulation in ULPI TLL modes. VBUS controls are writable, static PHY-side registers on the ULPI side, and input signals on the ULPI ports (port A). VBUS status bits are read-only, volatile PHY-side registers on the ULPI, and output signals on the ULPI ports (port A).

Table 22-48. Emulation of VBUS Levels for UTMI-to-ULPI TLL Mode

VBUS Controls (Actions)			VBUS Level	VBUS Status		
USBHOST.ULPI_OTG_CTRL[5]	USBHOST.ULPI_OTG_CTRL[4]	USBHOST.ULPI_OTG_CTRL[3]	USBHOST.ULPI_USB_VALID	USBHOST.ULPI_USB_INT_STATUS[1]	USBHOST.ULPI_USB_INT_STATUS[2]	USBHOST.ULPI_USB_INT_STATUS[3]
DRVVBUS Bit	CHRGVBUS Bit	DISCHRGVBUS Bit	Bit	Bit	SESSVALID Bit	SESEND Bit
1	X	X	VBUS valid	1	1	0
0	1	X	VBUS valid	0	1	0
0	0	X	Session end	0	0	1

22.2.4.2.4.2.2 VBUS Emulation in Serial TLL Modes

In serial TLL modes, VBUS status and control is implemented with ad-hoc sideband signals. See [Figure 22-19](#).

VBUS control can be done in software, by writing to the following fields of the [USBHOST.TLL_CHANNEL_CONF_i](#) register:

- DRVVBUS: Set to 1 to drive VBUS to 5 V (for A-device or host)
- CHRGVBUS: Set to 1 to pullup VBUS (for SRP)
- There is no pulldown (discharge) control, because the emulated VBUS has no latency and VBUS level goes to the session end level as soon as it is neither driven nor pulled up.

Alternatively, VBUS drive can also be hardware-controlled through a dedicated input. (DRVVBUS register bit and input signal are actually ORed internally.)

VBUS status is available on dedicated output signals. If those outputs are not available at top level, a software alternative is to use the voltage status reported on the local controller (the high-speed USB host controller in the device) interface (through the standard UTMI+ sideband signals) and to pass it to the remote controller (a peripheral controller), by means of an ad hoc software-controller interface other than the USB itself. This is based on the fact that the level of VBUS is the same on both extremities of the bus (that is, it does not matter which side does the measurement).

22.2.4.2.5 Multimode Serial Port

The multimode serial port requires six bidirectional I/O pads to support all eight defined modes (selected in the [USBHOST.TLL_CHANNEL_CONF_i\[27:24\]](#) FSLSMODE field when field CHANMODE = 0x1 = UTMI-to-serial). Those modes are full-speed/low-speed only (that is, high-speed is not supported over a serial interface).

The pads are named TXEN, TXDAT, TXSE0, RXRCV, and RXDM after their functionality in standard 6-pin mode (mode 0). Each pad has an input, output, and output enable signal associated to it on the USBTLL entity.

[Table 22-49](#) shows the functionality of each pad in each mode. USBTLL outputs are shown in yellow, inputs in blue, and bidirectional pads in green.

Table 22-49. Serial Mode Description, Signal Functionality

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL (Alt) Mode	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode
USBHOST.TLL_CH_ANNEL_CONF_i[27:24] FSLSMODE field	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7	0xA	0xB
TX encoding	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM
RX encoding	DP/DM/R CV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DAT/SE0	DP/DM
Pin usage	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Bidirectional	Bidirectional
Pin count	6	6	3	4	6 or 5 ⁽¹⁾	6 or 5 ⁽¹⁾	3	4 or 3 ⁽²⁾	2	2
I/O Pad Function Per Mode										
TXEN	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	N/C	N/C
TXDAT	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX SE Plus Data	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX SE Plus Data
TXSE0	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX SE Minus Data	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX force SE0	TX/RX force SE0	TX/RX SE Minus Data
RXRCV	RX Diff Data	RX Diff Data	N/C	RX Diff Data	RX Diff Data	RX Diff Data	N/C	RX Diff Data	N/C	N/C
RXDM	RX SE Plus Data	RX SE Plus Data	N/C	N/C	RX SE Plus Data	RX SE Plus Data	N/C	N/C	N/C	N/C
RXDM	RX SE Minus Data	RX SE Minus Data	N/C	N/C	RX SE Minus Data	RX SE Minus Data	N/C	N/C	N/C	N/C

⁽¹⁾ RXRCV and RXDM carry the same info: RXDM can drive both inputs of the remote controller and RXRCV kept unused

⁽²⁾ Same remark on TXDAT (for outputs) and RXRCV: TXDAT only is enough

22.2.4.2.6 Attach/Connect Emulation for Serial TLL Modes

This section applies to all serial TLL modes:

- In UTMI-to-serial mode (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x1) for all TLL values of USBHOST.TLL_CHANNEL_CONF_i[27:24] FSLSMODE field (0x4 to 0x7; 0xA to 0xB)
- In UTMI-to-ULPI TLL mode (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x0) when the ULPI bus is switched to 6-pin serial or 3-pin serial modes

In those modes, the USB bus lines are emulated by USBTLL internal logic, and are never available on the outside. The pullup/pulldown actions described in the USB specification cannot be applied directly, and the USB cable cannot be physically attached.

Because serial modes do not specify a standard format for those sideband settings, a custom software-controlled one was implemented:

- USBHOST.TLL_CHANNEL_CONF_i[4] TLLATTACH bit emulates the physical attachment of the two controllers through a TLL cable.
 - When this bit is cleared, the local controller RX path only shows the local controller (the high-speed USB host controller) actions on the bus: TX driving, pullups, pulldowns (see below). The same thing applies for the remote controller RX path (except that test override is not available).
 - As soon as the bit is set, the actions of both sides are applied to the same bus and are resolved, similar to a real bus. The RX path for both sides shows the same bus state.
- USBHOST.TLL_CHANNEL_CONF_i[5] TLLCONNECT bit emulates the USB electrical connect (that is,

the pullup by the USB peripheral of one of the two USB lines [by a 1.5KOhm resistor], which causes the linestate to transition from SE0 to J, which is detected by the USB host. The register bit is ORed with a USBTLL module input signal - the connect control can be software (L4-Core interconnect write access) or hardware (input level). The speed of the connection is determined by the TLLFULLSPEED bit below.

- **USBHOST.TLL_CHANNEL_CONF_i[6]** TLLFULLSPEED bit determines the speed (full or low) of the USB connect to be emulated. The connect enable (controlled as defined above) results in the pulling-up of either D+ (1 = full speed) or D- (0 = low speed): See [Table 22-50](#).
- The 15kOhm pulldowns are implicit: Because they are supposed to be turned on at least on the host side of the bus, they do not require an additional control.

NOTE: Sideband control and status actions like pullups are included in parallel (that is, nonserial) standards (UTMI, ULPPI), and do not require any custom additions.

Table 22-50. Pullup Enable Emulation in Serial TLL Modes

USBHOST.TLL_CHANNEL_CONF_i Fields		Input Signal	Resulting TLL Pullup Emulation	
TLLFULLSPEED	TLLCONNECT	USB State	D+ Pullup	D- Pullup
1	0	Full-speed unconnected	Off	Off
1	1	Full-speed connected	on	Off
0	0	Low-speed unconnected	Off	Off
0	1	Low-speed connected	Off	On

22.2.4.2.7 Save and Restore

The SAR mechanism can extract the hardware context of the USBTLL module (after all USB activity has been suspended) before switching off (=save), save it to an external always-on memory, and reinject it later after the module has been switched on again and reset (=restore) seamlessly for the USB. Part of that context is composed of the register fields described in the current chapter. The rest of the context is composed of the buried flip-flops and memories (not accessible by software) like FSM states, buffer contents, and miscellaneous random logic bits.

The PRCM.PM_PWSTCTRL_CORE[4] SAVEANDRESTORE bit enables the SAR mechanism for the USBTLL module (see [Chapter 3, Power, Reset, and Clock Management](#)). When set, the PRCM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

[Table 22-51](#) lists the USBTLL registers impacted by the SAR context.

NOTE: Because all addresses give access to the same physical register (that is, to the same piece of context), the ULPPI registers with multiple accesses (write, set, clear) are listed only once in the table.

Table 22-51. USBTLL Registers Impacted by the SAR Context

Register Name	Comments on SAR Policy
USBTLL_SYSCONFIG	Except the SOFTRESET bit (write-only)

22.2.5 High-Speed USB Host Subsystem Basic Programming Model

22.2.5.1 Selecting and Configuring USB Connectivity

Perform the following steps to select the desired USB connectivity and configure the device accordingly.

The high-speed USB host subsystem provides three kinds of interfaces for connection:

- ULPI PHY interfaces for high-speed data transactions (up to 480 Mbps)
- Serial interfaces for full- and low-speed data transactions (up to 12 Mbps)
- ULPI TLL interfaces for high-speed data transactions (up to 480 Mbps)

[Figure 22-34](#) shows how to select and configure the high-speed USB host subsystem connectivity.

Figure 22-34. Selecting and Configuring High-Speed USB Host Subsystem Connectivity

usb-034

Table 22-52. Register Call Summary for Selecting and Configuring High-Speed USB Host Subsystem Connectivity

Register Name
UHH_HOSTCONFIG
TLL_CHANNEL_CONF_i

Table 22-53. Subprocess Call Summary for Selecting and Configuring High-Speed USB Host Subsystem Connectivity

Subprocess Name	Cross reference
UHH_HOSTCONFIG[12] Pi_ULPI_BYPASS	Section 22.2.4.1.3, UTMI Ports
TLL_CHANNEL_CONF_i[2:1] CHANMODE	Section 22.2.4.2.3, Channel Configurations
TLL_CHANNEL_CONF_i[27:24] FSLSMODE	Section 22.2.4.2.6, Attach/Connect Emulation for Serial TLL Modes
TLL_CHANNEL_CONF_i[8] ULPIDDRMODE	Section 22.2.5.1.1, ULPI Interface Selection

NOTE:

- When the USBHOST.UHH_HOSTCONFIG[12] P3_ULPI_BYPASS bit is 0 (the port 3 ULPI transceiver interface selection), only the 12-pin/8-bit data SDR version of the ULPI interface mode is supported for port 3.
- When the USBHOST.UHH_HOSTCONFIG[11] P2_ULPI_BYPASS bit is 0, (the port 2 ULPI transceiver interface selection), only the 12-pin/8-bit data SDR version of the ULPI interface mode is supported for port 2.
- When the USBHOST.UHH_HOSTCONFIG[0] P1_ULPI_BYPASS bit is 0 (the port 1 ULPI transceiver interface selection), only the 12-pin/8-bit data SDR version of the ULPI interface mode is supported for port 1.
- When the USBHOST.UHH_HOSTCONFIG[12] P3_ULPI_BYPASS bit is 1, (the ULPI TLL interface selection and serial interface selection), there is no restriction and port 3 can be configured in any ULPI TLL or serial mode.
- When the USBHOST.UHH_HOSTCONFIG[11] P2_ULPI_BYPASS bit is 1 (the ULPI TLL interface selection and serial interface selection), there is no restriction and port 2 can be configured in any ULPI TLL or serial mode.
- When the USBHOST.UHH_HOSTCONFIG[0] P1_ULPI_BYPASS bit is 1 (ULPI TLL interface selection and serial interface selection), there is no restriction and port 1 can be configured in any ULPI TLL or serial mode.

22.2.5.1.1 ULPI Interface Selection

The high-speed USB host subsystem supports the following modes with the ULPI interfaces:

- External USB transceiver
 - ULPI interfaces: 12-pin/8-bit data version
- TLL
 - ULPI TLL interfaces: 12-pin/8-bit data version or 8-pin/4-bit data version

22.2.5.1.1.1 Transceiver Interfaces

The USBTLL module is bypassed and the high-speed USB host controller ports 1 and 2 are connected directly to external transceivers.

The high-speed USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI interface mode. The high-speed USB host controller uses its ULPI ports (UTMI ports cannot be used). The USBHOST.UHH_HOSTCONFIG[12] P3_ULPI_BYPASS, USBHOST.UHH_HOSTCONFIG[11] P2_ULPI_BYPASS, or USBHOST.UHH_HOSTCONFIG[0] P1_ULPI_BYPASS bit must be cleared to 0, depending on the port used in ULPI mode.

22.2.5.1.1.2 TLL

The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The high-speed USB host controller uses its UTMI ports (bypassing the ULPI ports). The USBHOST.UHH_HOSTCONFIG[12] P3_ULPI_BYPASS, USBHOST.UHH_HOSTCONFIG[11] P2_ULPI_BYPASS, or USBHOST.UHH_HOSTCONFIG[0] P1_ULPI_BYPASS bit must be set to 1, depending on the port used in UTMI mode.

At the USBTLL module level, a channel configuration for ULPI TLL interfaces must be set (see [Section 22.2.4.2.3, Channel Configurations](#)).

Two configurations are supported for ULPI TLL interfaces in the device:

- Configuration 2: ULPI synchronous TLL mode
- Configuration 4: Serial UTMI to serial ULPI TLL mode

In both configurations, the USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field must be cleared to 0x0 (UTMI-to-ULPI TLL mode).

The selection of the ULPI TLL interface version, 12-pin/8-bit data version (SDR mode) or 8-pin/4-bit data version (DDR mode) is done through the USBHOST.TLL_CHANNEL_CONF_i[8] ULPIDDRMODE bit (0: SDR mode; 1: DDR mode).

22.2.5.1.2 Serial Interface Selection

The high-speed USB host subsystem supports the following modes with the serial interfaces:

- External USB transceiver configurations
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin unidirectional (TX: DAT/SE0 or TX: DP/DM), 4-pin bidirectional and 3-pin bidirectional modes
- TLL configurations
 - Serial 6-pin TLL interfaces: 6-pin unidirectional (TX: DAT/SE0 or TX: DP/DM), 4-pin bidirectional, 3-pin bidirectional, and 2-pin bidirectional modes

The high-speed USB host controller is coupled with the USBTLL module to compose the serial interface modes.

The high-speed USB host controller uses its UTMI ports (bypassing the ULPI ports). The USBHOST.UHH_HOSTCONFIG[12] P3_ULPI_BYPASS, USBHOST.UHH_HOSTCONFIG[11] P2_ULPI_BYPASS, or USBHOST.UHH_HOSTCONFIG[0] P1_ULPI_BYPASS bit must be set to 1, depending on the port. In UTMI mode, all ports of the high-speed USB host controller are in UTMI mode.

At the USBTLL module level, a channel configuration for serial interfaces must be set (see [Section 22.2.4.2.3, Channel Configurations](#)).

One configuration is supported for serial interfaces in the device, the Configuration 6 including two modes:

- Serial UTMI to serial TLL
- Serial UTMI to serial PHY

The multimode-mode serial interface mode selection is done through the USBHOST.TLL_CHANNEL_CONF_i[27:24] FSLSMODE field only when the main channel mode is serial (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x1 = UTMI-to-serial mode).

Table 22-54. USB Connectivity Mode Description

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL Mode (Alt)	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode
USBHOST.TLL_CHANNEL_CONF_i[27:24] FSLSMODE field	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7	0xA	0xB
TX encoding	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM

Pin count	6	6	3	4	6 or 5 ⁽¹⁾	6 or 5 ⁽¹⁾	3	4 or 3 ⁽²⁾	2	2

⁽¹⁾ RxRCV and RxDP carry the same info: RxDP can drive both inputs of the remote controller and RxRCV kept unused

⁽²⁾ Same remark on TXDAT (for outputs) and RxRCV: TXDAT only is enough

22.2.5.2 USBTLL Registers

The USBTLL module contains two types of software-programmable registers.

22.2.5.2.1 TLL Control and Status Registers

These 32-bit registers configure the various channels. These registers are accessed by the MPU through the L4-Core interconnect. They are used mostly before the actual USB activity starts. These registers are:

-
- Standard registers for revision number, IRQ, clocking management, etc.
 - TLL-specific registers

22.2.5.2.2 ULPI PHY-side Registers

Each TLL channel emulates a ULPI transceiver and accordingly contains this set of 8-bit PHY-side registers, per ULPI specification. Those registers are:

- All ULPI-mandatory standard registers and fields
- A selection of ULPI-optional standard registers and fields, when relevant to the TLL context
- Vendor-specific registers, mapped at the addresses specified for that purpose in ULPI specification

Those registers are accessed by the external (that is, off-chip) link controller over the ULPI port of each channel, in the 0x100-byte ULPI address space, using the ULPI register access protocol.

Those registers are accessible by the L4-Core interconnect: The ULPI register sets of all channels are mapped side by side in the upper part of the L4-Core interconnect address space, where they can be accessed through byte accesses. In case of conflict between the two access modes, the access over ULPI will have priority, but both accesses will eventually complete correctly. For normal USB activity, all register accesses are expected to go over ULPI, and register changes caused by L4-Core interconnect accesses could compromise proper USB operation. The L4-Core interconnect access port is intended for:

- Miscellaneous test and debug
- Nonintrusive observation of ongoing USB operations (test)
- Context restore: During USB suspend periods, the USBTLL module can be switched off to save power. Upon resume, the ULPI register contents have been lost and can be restored over L4-Core interconnect before USB operations restarts, provided they have been saved elsewhere beforehand.

22.2.6 High-Speed USB Host Subsystem Register Manual

22.2.6.1 USBTLL ULPI PHY-Side Register Space

Each ULPI port emulates a separate ULPI transceiver and as such gives access to a single set of ULPI PHY-side registers, mapped in a separate ULPI register space as specified in the ULPI specification. The ULPI protocol defines two register access methods: Immediate and extended.

- The immediate space maps ULPI PHY-side registers in a 0x400- (64-) byte space (address is 6 bits wide). All ULPI PHY-side registers implemented in the USBTLL implementation are in the immediate space.
- The extended register space maps all ULPI PHY-side registers in a 0x1000- (256-) byte space (address is 8 bits wide). The immediate space is remapped at the bottom of the extended space (that is, the extended access method can be used to access any ULPI register).

An access is recognized as extended by first pointing to a reserved dummy address 0x2F (EXTENDED_SET_ACCESS in [Table 22-56](#)). Immediate-mode accesses to this address over the ULPI interface are forbidden by the protocol and the USBTLL behavior is then undefined. Extended accesses to this address have no effect.

Some physical registers are accessible at more than one address, where write accesses perform different actions on the register value: (over-)write, set, clear. A read to any of the addresses returns the register value. The names of the set and clear registers are the write name postfixed with respectively _SET and _CLR. The register fields are described only once, at the write address (see [Section 22.2.6.4.1, USBTLL Registers](#)).

NOTE: Some ULPI registers are cleared upon read.

22.2.6.2 L4-Core Interconnect Register Space

[Table 22-55](#) lists the base address and address space for the high-speed USB host subsystem.

Table 22-55. High-Speed USB Host Subsystem Instance Summary

Module Name	Base Address (hex)	Size
USBTLL	0x4806 2000	4096 bytes
UHH_config	0x4806 4000	1024 bytes
OHCI	0x4806 4400	1024 bytes
EHCI	0x4806 4800	1024 bytes

22.2.6.3 High-Speed USB Host Subsystem Register Summary

The USBTLL single L4-Core interconnect gives access to both the TLL control and status registers, and the ULPI PHY-side registers.

[Table 22-56](#) lists all the USBTLL registers mapped by the L4-Core interconnect, for the maximum 8-channel configuration.

CAUTION**On ULPI PHY-side register access over L4-Core interconnect:**

ULPI registers are byte-sized, and can only be accessed in this size. Attempts to access them over L4-Core interconnect using any other data size (16- or 32-bit) will complete without error (or any other warning), but will result in undefined behaviors.

The following cases can cause problems:

- If the ULPI register contents are defined as static (nonvolatile) by the software, a cache update may result in a burst of 32-bit access, with unwanted consequences.
- Some registers have adjacent overwrite, set, and clear addresses. An oversized write access could clear and set the same bit, which can have several results.
- Some registers are cleared on read: Oversized read accesses to adjacent memory locations could cause unwanted clears.

www.ti.com

Bits	Field Name	Description	Type	Reset
31:7	RESERVED	Reserved	R	0x0000000
6	USB_90D_DDR_EN	Software enable/disable of the 90-degree phase shift scheme on output DDR data, when implemented. Read-only, always-0 when HDL generic ULPI_90DEG4DDR = 0. 0x0: ULPI DDR output DATA aligned with CLK 0x1: ULPI DDR output DATA delayed by 90 degree wrt CLK	RW	0x1
5	USB_180D_SDR_EN	Software enable/disable of the 180-degree phase shift scheme on output SDR data, when implemented. Read-only, always-0 when HDL generic ULPI_180DEG4SDR = 0 0x0: ULPI SDR output DATA aligned with CLK 0x1: ULPI SDR output DATA delayed by 180 degree wrt CLK	RW	0x1
4:2	USB_DIVRATIO	(Log2 of) division ratio from functional clock to USB (UTMI/ULPI) clock 0x0: Div ratio is $2^{**}0 = 1$: Bypass 0x1: Div ratio is $2^{**}1 = 2$ 0x2: Div ratio is $2^{**}2 = 4$ 0x3: Div ratio is $2^{**}3 = 8$ 0x4: Div ratio is $2^{**}4 = 16$ 0x5: Div ratio is $2^{**}5 = 32$ 0x6: Div ratio is $2^{**}6 = 64$ 0x7: Div ratio is $2^{**}7 = 128$	RW	0x0
1	FCLK_REQ	Functional clock request, ORed from all channels depending on their respective USB bus state. Combined with the Fclk_is_on status to generate fclk_start/end IRQs. 0x0: Func clock input is not requested by TLL 0x1: Func clock input is requested by TLL	R	0x0
0	FCLK_IS_ON	Status of the functional clock input, provided by the system to the TLL module. The TLL module will only use that clock if the current status indicated that it is ready. Combined with the Fclk_request to generate fclk_start/end IRQs. 0x0: Functional clock input is not guaranteed ON (can actually be ON, OFF, or unstable) 0x1: Functional clock input is guaranteed ON and stable	RW	0x0

High-Speed USB Host Subsystem

www.ti.com

Bits	Field Name	Description	Type	Reset
18	TESTTXEN	Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) 0x0: Drive TX according to TestTXDat/Se0 0x1: Drive TX Hiz (no drive: Pullups determine line state)	RW	0x0
17	TESTEN	Enable manual test override for serial mode TX path (from local controller's UTMI port) 0x0: No override. TX is from local link controller 0x1: Override enabled	RW	0x0
16	DRVVBUS	VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS drive * In PHY config, write 1 to report "VBus valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not driven 0x1: VBUS driven to 5V	RW	0x0
15	CHRGVBUS	VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS charge/pullup (OTG) * In PHY config, write 1 to reports "session valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not charged, session not valid 0x1: VBUS charged, session valid	RW	0x0
14:12	RESERVED	Reserved	R	0x0
11	ULPINOBITSUFF	Disable bitstuff emulation in ULPI TLL for ULPI ChanMode 0x0: Bitstuff enabled, following USB standard 0x1: No bitstuff or associated delays (non-standard)	RW	0x0
10	ULPIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the ULPI output clock to be stopped when ULPI goes into asynchronous mode (low-power, 3-pin serial, 6-pin serial). No effect in ULPI input clock mode. 0x0: ULPI output clock always-on 0x1: ULPI output clock stops during asynchronous ULPI modes	RW	0x1
9	UTMIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the UTMI clock (output) to be stopped when UTMI goes to suspended mode (suspendm = 0) 0x0: UTMI clock output always on 0x1: UTMI clock output gated upon suspend	RW	0x1
8	ULPIDDRMODE	Select single/double data rate (SDR/DDR) mode for ULPI TLL Reset value depends on hardware generics ULPI_SDR/DDR_MODE. 0x0: SDR mode (8 data bit/12 pin) 0x1: DDR mode (4 data bit/8 pin)	RW	0x0
7	ULPIOUTCLKMODE	ULPI clocking mode select for ULPI TLL ChanMode 0x0: ULPI clock provided by LINK (that is, off-chip). ULPI clock is input 0x1: ULPI clock provided by PHY side (that is, TLL, from functional clock). ULPI clock is output	RW	0x1
6	TLLFULLSPEED	Sets PHY speed emulation in TLL (full/slow), which determines the line to pull up upon connect. The two connect source controls are: Input m(N)_tlpuen, register field TIIConnect. 0x0: Connect is Low-speed: D- pullup 0x1: Connect is Full-Speed: D+ pullup	RW	0x1

Bits	Field Name	Description	Type	Reset
5	TLLCONNECT	Emulation of Full/Low-Speed connect (that is, D+ resp D-pullup) for serial TLL modes. Speed is determined by field TLLSpeed. 0x0: Unconnected 0x1: Connected	RW	0x0
4	TLLATTACH	Emulates cable attach/detach for all serial TLL modes: * ChanMode = serial, in TLL mode (FsLsMode) * ChanMode = ULPI, in serial mode (6pin/3pin TLL) 0x0: Cable detach emulated on serial TLL 0x1: Cable attach emulated on serial TLL	RW	0x1
3	UTMIIISADEV	Select the cable end "seen" by UTMI side of TLL, that is, the emulated USB cable's orientation. Note that host must always be on A side, Peripheral on B side. Reset value depends on generic DEFUTMIISSHOST. 0x0: UTMI side is peripheral, ULPI side is host 0x1: UTMI side is host, ULPI side is peripheral	RW	0x1
2:1	CHANMODE	Main channel mode selection 0x0: UTMI-to-ULPI TLL mode (HS capable): To ULPI controller 0x1: UTMI-to-serial (FS/LS) mode: To serial controller (TLL) or serial PHY 0x2: Transparent UTMI mode: To UTMI PHY 0x3: No mode selected	RW	0x0
0	CHANEN	Active-high channel enable. A disabled channel is unclocked and kept under reset. 0x0: Channel #N disabled 0x1: Channel #N enabled	RW	0x0

Physical Address	0x4806 2833 + (0x100 * i)	Instance	USBTLL
Description	Part of non-standard UTMI-to-ULPI mailbox system, implemented if HDL generic VCS_MAILBOX bit is 1 UTMI-standard Vcontrol vector byte is sent by the UTMI controller (other side of TLL) to its PHY (emulated here by the TLL). Alternatively, data can be also written directly into the register. Can contain any user-defined data. Vcontrol bit changes can be used to assert the ULPI ALT interrupt. Lowest VCS_CTRL_WIDTH (HDL generic) bits are implemented, others are always-0, read-only. (UTMI standard is 4-bit).

			RESERVED	
				RESERVED

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	R	0x00000000
12	P3_ULPI_BYPASS	Host controller (root hub) port 3 control. 0x0: ULPI port 3 is active (and UTMI port 3 is inactive) 0x1: UTMI port 3 is active (and ULPI port 3 is inactive)	RW	0

High-Speed USB Host Subsystem

www.ti.com

Bits	Field Name	Description	Type	Reset
11	P2_ULPI_BYPASS	Host controller (root hub) port 2 control. 0x0: ULPI port 2 is active (and UTMI port 2 is inactive) 0x1: UTMI port 2 is active (and ULPI port 2 is inactive)	RW	0
10	P3_CONNECT_STATUS	Connection status for port 3. 0x0: USB port 3 is disconnected 0x1: USB port 3 is connected and in use (also the default state)	RW	0x1
9	P2_CONNECT_STATUS	Connection status for port 2. 0x0: USB port 2 is disconnected 0x1: USB port 2 is connected and in use (also the default state)	RW	0x1
8	P1_CONNECT_STATUS	Connection status for port 1. 0x0: USB port 1 is disconnected 0x1: USB port 1 is connected and in use (also the default state)	RW	0x1
7:6	RESERVED	Reserved	RW	0x0
5	ENA_INCR_ALIGN	Force alignment of bursts to the respective burst-size boundaries ⁽¹⁾ 0x0: Disable burst type 0x1: Enable burst type	RW	0x0
4	ENA_INCR16	Control the use of INCR16-type bursts (in AHB sense) 0x0: Disable burst type 0x1: Enable burst type	RW	0x0
3	ENA_INCR8	Control the use of INCR8-type bursts (in AHB sense) 0x0: Disable burst type 0x1: Enable burst type	RW	0x0
2	ENA_INCR4	Control the use of INCR4-type bursts (in AHB sense) 0x0: Disable burst type 0x1: Enable burst type	RW	0x0
1	AUTOPPD_ON_OVERCUR_EN	Configure reaction upon port overcurrent condition 0x0: Port remains on upon overcurrent 0x1: Port is powered down automatically upon overcurrent Note: The bit must not be used, and is always written to with its default (reset) value as the hardware overcurrent inputs are tied off at device level.	RW	0x0
0	P1_ULPI_BYPASS	Host controller (root hub) port 1 control. 0x0: ULPI port 1 is active (and UTMI port 1 is inactive) 0x1: UTMI port 1 is active (and ULPI port 1 is inactive)	RW	0

⁽¹⁾ This bit must be set to 1 to avoid buffer underflow.

POTPG	RESERVED				
		NOCP OCPM DT NPS PSM	NDP		

Bits	Field Name	Description	Type	Reset
31:24	POTPG	Power-on to power-good time. Defines the minimum amount of time (2 ms * POTPG) between the USB host controller turning on power to a downstream port and when the USB host can access the downstream device.	RW	0x0A
23:13	RESERVED	Reserved	R	0x000
12	NOCP	No overcurrent protection. 0x0: Overcurrent status is reported collectively for all downstream ports. 0x1: The USB host controller does not implement overcurrent protection inputs Note: The bit must not be used, and is always written to with its default (reset) value as the hardware overcurrent inputs are tied off at device level.	RW	0
11	OCPM	Overcurrent protection mode. Note: The bit must not be used, and is always written to with its default (reset) value as the hardware overcurrent inputs are tied off at device level.	RW	1
10	DT	Device type. Always reads 0x0: Indicates that the USB host controller implemented is not a compound device.	R	0
9	NPS	No power switching 0x0: VBUS power switching is supported, either per-port or all-port switched per the power 0x1: VBUS power switching is not supported, power is available to all downstream ports.	RW	0
8	PSM	Power switching mode. 0x0: Indicates that all ports are powered at the same time 0x1: Individual port power switching is supported	RW	1
7:0	NDP	Number of downstream ports. These bits specify the number of downstream ports supported by the root hub. It is implementation-specific. The minimum number of ports is 1. The maximum number of ports supported by OHCI is 15.	R	0x03

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Reserved	R	0x00
23:16	ITC	Interrupt Threshold Control This field is used by the system software to select the maximum rate at which the host controller issues interrupts. The only valid values are defined below. If software writes an invalid value to this register, the results are undefined. 0x00: Reserved 0x01: 1 microframe 0x02: 2 microframes 0x04: 4 microframes 0x08: 8 microframes (default, equates to 1 ms) 0x10: 16 microframes (2 ms) 0x20: 32 microframes (4 ms) 0x40: 64 microframes (8 ms) Others: Undefined	RW	0x08
15:12	RESERVED	Reserved	R	0x0
11	ASPME	Asynchronous Schedule Park Mode Enable 0x0: Park mode is disabled. 0x1: Park mode is enabled.	RW	1
10	RESERVED	Reserved	R	0
9:8	ASPMC	Asynchronous Schedule Park Mode Count It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the asynchronous schedule before continuing traversal of the asynchronous schedule. Valid values are 0x1 to 0x3. The software must not write a 0 to this bit when Park Mode Enable is a 1 as this may result in undefined behavior.	RW	0x3
7	LHCR	Light Host Controller Reset It allows the driver to reset the EHCI controller without affecting the state of the ports or the relationship to the companion host controllers. Read 0x0: Light host controller reset is complete and it is safe for host software to reinitialize the host controller. Read 0x1: Light host controller reset is still ongoing.	RW	0
6	IAAD	Interrupt on Async Advance Doorbell This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Write 0x1: Ring the doorbell. Software should not write a 1 to this bit when the asynchronous schedule is disabled. Doing so may yield undefined results.	RW	0
5	ASE	Asynchronous Schedule Enable This bit controls whether the host controller skips processing the asynchronous schedule. 0x0: Do not process the asynchronous schedule 0x1: Use the USBHOST.ASYNCLISTADDR register to access the asynchronous schedule.	RW	0
4	PSE	Periodic Schedule Enable This bit controls whether the host controller skips processing the periodic schedule. 0x0: Do not process the periodic schedule	RW	0

High-Speed USB Host Subsystem

14	PSS	<p>Periodic Schedule Status</p> <p>The bit reports the current real status of the periodic schedule.</p>	R	0

Bits	Field Name	Description	Type	Reset
		0x0: The status of the periodic schedule is disabled. 0x1: The status of the periodic schedule is enabled.		
13	REC	Reclamation It is used to detect an empty asynchronous schedule.	R	0
12	HCH	Host Controller Halted This bit is a 0 whenever the USBHOST.USBCMD[0] RS bit is a 1. The host controller sets this bit to 1 after it has stopped executing as a result of the RS bit being set to 0, either by software or by the host controller hardware.	R	1
11:6	RESERVED	Reserved	R	0x00
5	IAA	Interrupt on Async Advance System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a 1 in the USBHOST.USBCMD[6] IAAD bit. This status bit indicates the assertion of that interrupt source.	RW	0
4	HSE	Host System Error The host controller sets this bit to 1 when a serious error occurs during a host system access involving the host controller module.	RW	0
3	FLR	Frame List Rollover The host controller sets this bit to 1 when the USBHOST.FRINDEX rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size.	RW	0
2	PCD	Port Change Detect The host controller sets this bit to 1 when any port for which the USBHOST.PORTSC_I[13] PO bit is set to 0 has a change bit transition from a 0 to a 1 or a USBHOST.PORTSC_I[6] FPR bit transition from a 0 to a 1. This bit is also set as a result of the USBHOST.PORTSC_I[1] CSC bit being set to 1 after system software has relinquished ownership of a connected port by writing a 1 to a USBHOST.PORTSC_I[13] PO bit.	RW	0
1	USBEI	USB Error Interrupt The host controller sets this bit to 1 when completion of a USB transaction results in an error condition.	RW	0
0	USBI	USB Interrupt The host controller sets this bit to 1 on completion of a USB transaction, which results in the retirement of a transfer descriptor that had its IOC bit set. The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes).	RW	0

Memory Stick PRO Host Controller

This chapter presents an overview of the Memory Stick PRO™ host controller in the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
23.1 Memory Stick PRO Host Controller Overview	3392

23.1 Memory Stick PRO Host Controller Overview

The Memory Stick PRO host controller provides the device with an interface between a microprocessor unit (MPU) local host (LH) and either a Memory Stick® or a Memory Stick PRO card.

The Memory Stick PRO host controller is connected to the L4-Core interconnect.

Figure 23-1 shows an overview of the Memory Stick PRO host controller.

Figure 23-1. Memory Stick PRO Host Controller Overview

ms-pro-001

23.1.1 Main Features

The Memory Stick PRO host controller includes the following main features:

- Supports Memory Stick v1.x and Memory Stick PRO
- Data transmit/receive internal first-in first-out (FIFO) (64 bits x 4)
- Cyclic redundancy check (CRC) circuit
- Memory Stick serial clock (Memory Stick v1.x: 19.2 MHz; Memory Stick PRO: 32 MHz with 96-MHz functional clock source)
- Direct memory access (DMA) supported
- Lower 16-/32-bit access possible
- Little endian (internally big endian)
- L4 interconnect support

NOTE: Other information about Memory Stick PRO host controller are not available in the public domain.

MMC/SD/SDIO Card Interface

This chapter describes the features and functions of the multimedia card/SD/SD I/O (MMC/SDIO) card interface.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

24.7 MMC/SD/SDIO Register Manual	3454

24.1 MMC/SD/SDIO Overview

The multimedia card high-speed/SD/SD I/O (MMC/SD/SDIO) host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either MMC, SD memory cards, or SDIO cards and handles MMC/SD/SDIO transactions with minimal LH intervention.

The application interface manages transaction semantics. The MMC/SD/SDIO host controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRC), start/end bit, and checking for syntactical correctness.

The application interface can send every MMC/SD/SDIO command and either poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SD/SDIO host controller also supports two DMA channels.

There are three MMC/SD/SDIO host controllers inside the device: [Figure 24-1](#) gives an overview of the MMC/SD/SDIO controller instances 1 and 3, and [Figure 24-2](#) gives an overview of the MMC/SD/SDIO2 controller instance.

Figure 24-1. MMC/SD/SDIO1 and 3 Overview

Figure 24-2. MMC/SD/SDIO2 Overview

24.1.1 MMC/SD/SDIO Features

The main features of the MMC/SD/SDIO host controller are:

- Full compliance with MMC command/response sets as defined in the *Multimedia Card System Specification*, v4.2 including high-capacity (size > 2GB) cards HC MMC.
- Full compliance with SD command/response sets as defined in the *SD Memory Card Specifications*, v2.0 including high-capacity SDHC cards up to 32GB.
- Full compliance with SDIO command/response sets and interrupt/read-wait mode as defined in the *SDIO Card Specification, Part E1*, v2.00
- Full compliance with sets as defined in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v2.00
- Full compliance with MMC bus testing procedure as defined in the *Multimedia Card System Specification*, v4.2
- Full compliance with CE-ATA command/response sets as defined in the *CE-ATA Standard Specification*
- Full compliance with ATA for MMCA specification
- Flexible architecture allowing support for new command structure
- Support:
 - 1-bit or 4-bit transfer mode specifications for SD and SDIO cards
 - 1-bit, 4-bit, or 8-bit transfer mode specifications for MMC cards (1-bit and 4-bit only available for instance 1)
- Built-in 1024-byte buffer for read or write
- 32-bit-wide access bus to maximize bus throughput
- Single interrupt line for multiple interrupt source events
- Two slave DMA channels (1 for TX, 1 for RX)

- Designed for low power
- Programmable clock generation
- Support SDIO Read Wait and Suspend/Resume functions
- Support Stop at block gap
- Support command completion signal (CCS) and command completion signal disable (CCSD) management as specified in the *CE-ATA Standard Specification*

The known limitations are as follows:

- No built-in hardware support for error correction codes (ECC). See the *Multimedia Card System Specification*, v4.2, and the *SD Memory Card Specifications*, v2.0, for details about ECC.
- The maximum block size defined in the *SD Memory Card Specifications*, v2.0, that the host driver can read and write to the buffer in the host controller is 2048 bytes. MMC supports a maximum block size of 1024 bytes. Up to 512 byte transfers, the buffer in MMC is considered as a double buffering with ping-pong management; half of the buffer can be written while the other part is read. For 512 to 1024 byte transfers, the entire buffer is dedicated to the transfer (read only or write only).

NOTE: MMC/e.MMC compliance versus the *Multimedia Card System Specification*, v4.3 (or v4.4):

Full compliance with the MMC command/response sets and MMC bus testing procedure, as defined in the *Multimedia Card System Specification*, v4.2, does not prevent the use of e.MMC version 4.3 (or 4.4) devices with the OMAP36xx, because e.MMC devices are backward compatible. Only the e.MMC version 4.3 (or 4.4) boot operation is not supported in the OMAP36xx. Boot operation in the OMAP36xx follows the TI booting scheme, ID booting from standard memory array.

The differences between the MMC/SD/SDIO host controllers and a standard SD host controller are defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, as follows:

- The MMC/SD/SDIO host controllers support MMC cards.
- The MMC/SD/SDIO host controller is defined as a DMA slave device. A standard SD host controller is defined as a DMA master controller that can start and stop a DMA transfer. MMC/SD/SDIO host controllers support DMA transfers through slave DMA requests.
- The clock divider in MMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications*, v2.0. The MMC/SD/SDIO host controller supports odd and even clock ratio.
- The MMC/SD/SDIO host controller supports configurable busy time-out.

24.2 MMC/SD/SDIO Environment

One MMC/SD/SDIO host controller can support one MMC memory card, one SD memory card, or one SDIO card.

Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

- The first controller (MMC/SD/SDIO1) integrates an internal transceiver that allows a direct connection to the MMC/SD/SDIO card (1.8 and 3V), without external transceiver. It supports 1-bit and 4-bit data transfer modes.
- The second controller (MMC/SD/SDIO2) allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (WLAN device for example). The second instance also supports an external transceiver and provides direction signals for data and command. It supports 1-bit, 4-bit and 8-bit data transfer modes. Using an external transceiver device precludes 8-bit transfer mode.
- The third controller (MMC/SD/SDIO3) allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (Wireless USB card for example). This interface is used without external transceiver. It supports 1-bit, 4-bit and 8-bit data transfer modes.

24.2.1 MMC/SD/SDIO Connected to MMC, SD, or SDIO Card

Figure 24-3 shows MMC/SD/SDIOi host controller, instance 1, 2 or 3, connected to an MMC, an SD, or an SDIO card and its related external connections.

Figure 24-3. MMC/SD/SDIO Connected to MMC, SD, or SDIO Card Without External Transceiver

mmchs-002

24.2.2 MMC/SD/SDIO Connected to MMC, SD, or SDIO Card Through an External Transceiver Device

This connection is supported only by the MMC/SD/SDIO2 host controller. Figure 24-4 shows the MMC/SD/SDIO2 host controller connected to an MMC, an SD, or an SDIO card through an external transceiver device.

Figure 24-4. MMC/SD/SDIO2 Connected to MMC, SD, SDIO Card with External Transceiver

mmchs-003

24.2.3 MMC/SD/SDIO Functional Interfaces

24.2.3.1 Basic MMC/SD/SDIOi Pins Without External Transceiver

Figure 24-5 shows the MMC/SD/SDIOi host controller interface signals (instance 1, 2 or 3).

Figure 24-5. MMC/SD/SDIOi Interface Signals

mmchs-004

Table 24-1 describes the MMC/SD/SDIOi inputs/outputs.

Table 24-1. MMC/SD/SDIOi I/O Description

Signal Name	I/O ⁽¹⁾	Description	Reset Value
mmci_clk	O	External clock for MMC/SD/SDIO card ⁽²⁾	0
mmci_cmd	I/O	Command signal	0
mmci_dat[3:0]	I/O	Data signals	0

⁽¹⁾ I = Input; O = Output

⁽²⁾ This output signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

Table 24-1. MMC/SD/SDIOi I/O Description (continued)

Signal Name	I/O ⁽¹⁾	Description	Reset Value
mmc1_dat[7:4]	I/O	Data signals (only for instance 2 and 3)	0

24.2.3.2 Basic MMC/SD/SDIO2 Pins With External Transceiver

Figure 24-6 shows the MMC/SD/SDIO2 host controller interface signals.

Figure 24-6. MMC/SD/SDIO2 Interface Signals

mmchs-005

Table 24-2 describes the MMC/SD/SDIO2 inputs/outputs.

Table 24-2. MMC/SD/SDIO2 I/O Description

Signal Name	I/O	Description	Reset Value
mmc2_clk	O	External clock for MMC/SD/SDIO card	0
mmc2_clkin	I	Input clock from MMC/SD/SDIO card	0
mmc2_cmd	I/O	Command signal	0
mmc2_dir_cmd	O	Direction control for mmc2_cmd signal case an external transceiver is used (high when transmit, low when receive)	0
mmc2_dat[3:0]	I/O	Data signals	0
mmc2_dir_dat0	O	Direction control for mmc2_dat0 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat1	O	Direction control for mmc2_dat1 and mmc2_dat3 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat2	O	Direction control for mmc2_dat2 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat3	O	Direction control for mmc2_dat[7:4] signal when an external transceiver is used (high when transmit, low when receive). Unusable on the device because mmc1_dat[7:4] are muxed with other direction control signals. See Chapter 13, System Control Module for further details on the pin multiplexing.	0

24.2.3.3 MMC/SD/SDIO Protocol and Data Format

The bus protocol between the MMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

Command: a command starts an operation. The command is transferred serially from the MMC/SD/SDIO host controller to the card on the mmc1_cmd line.

Response: a response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the mmc1_cmd line.

Data: data are transferred from the MMC/SD/SDIOi host controller to the card or from a card to the MMC/SD/SDIO host controller using the DATA lines.

Busy: the mmci_dat0 signal is maintained low by the card as far as it is programming the data received.

CRC status: CRC result is sent by the card through the mmci_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on mmci_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on mmci_dat0 and starts the data programming procedure.

24.2.3.3.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, and the *SDIO Card Specification, Part E1*, August 2004, for details about commands and programming sequences supported by the MMC, SD, and SDIO cards.

Figure 24-7 and Figure 24-8 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmci_cmd line.

CAUTION

Stream commands are supported only by MMC cards.

Figure 24-7. Sequential Read Operation (MMC Cards Only)

Figure 24-8. Sequential Write Operation (MMC Cards Only)

[Figure 24-9](#) and [Figure 24-10](#) show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmci_cmd line. These operations are available for all kinds of cards.

Figure 24-9. Multiple Block Read Operation

mmchs-008

Figure 24-10. Multiple Block Write Operation with Card Busy Signal

mmchs-009

NOTE:

1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. It is software responsibility to do a software reset (set MMCI.[MMCHS_SYSCTL\[26\]](#) SRD bit to 0x1) after data timeout to ensure mmci_clk is stopped
3. For multiblock transfer, and especially for MMC cards, you can abort a transfer without using a stop command. Use a CMD23 before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

24.2.3.3.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see [Figure 24-11](#)).

Figure 24-11. Command Token Format

Coding Scheme for Response Token

Response tokens always start with 0 and end with a 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5 R6 [for SDIO]) and the content is protected by 7-bit CRC checksum (see [Figure 24-12](#) and [Figure 24-13](#)). Depending on the type of commands sent to the card, the [MMCHS_CMD](#) register must be configured differently to avoid false CRC or index errors to be flagged on command response (see [Table 24-3](#)). For more details about response types, see the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, or the *SDIO Card Specification, Part E1*, v1.10.

Figure 24-12. Response Token Format (R1, R3, R4, R5, R6)

Figure 24-13. Response Token Format (R2)

Table 24-3. Relation Between Configuration and Name of Response Type⁽¹⁾

Response Type MMCi.MMCHS_CMD[17:16] RSP_TYPE	Index Check Enable MMCi.MMCHS_CMD[20] CICE	CRC Check Enable MMCi.MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5
11	1	1	R1b, R5b

⁽¹⁾ The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, whatever the value set in the MMCi.MMCHS_SYSConfig[9:8] CLOCKACTIVITY bit.

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see [Figure 24-14](#), [Figure 24-15](#), and [Figure 24-16](#)).

Figure 24-14. Data Token Format for 1-Bit Transfers

Figure 24-15. Data Token Format for 4-Bit Transfers

Figure 24-16. Data Token Format for 8-Bit Transfers

mmchs-015

24.3 MMC/SD/SDIO Integration

[Figure 24-17](#) shows the internal connections between the three instances of the MMC/SD/SDIO host controller and the other modules

Figure 24-17. MMC/SD/SDIO1 Integration

mmchs-016

24.3.1 Clocking, Reset, and Power-Management Scheme

24.3.1.1 Clocks

24.3.1.1.1 Module Clocks

The MMC/SD/SDIO receives three clocks:

- A fixed functional clock of 96 MHz (the MMC_i_FCLK) independent of the device external clock frequency
- An interface clock (the MMC_i_ICLK) for interfacing with L4 interconnects (register accesses)
- A debounce clock, the MMC_i_32K for reset process only

All these clocks are generated and controlled by the power, reset, and clock manager (PRCM) module (see [Chapter 3, Power, Reset, and Clock Management](#) for more information).

24.3.1.1.2 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the PRCM module handshake protocol.

Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCI.[MMCHS_SYSCONFIG\[0\]](#) AUTOIDLE bit is set to 1 (I = 1 for MMC/SD/SDIO1, 2 for MMC/SD/SDIO2 and 3 for MMC/SD/SDIO3 instances).
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (an interrupt from a SDIO card).
- A transaction on the MMC/SD/SIO interface starts.

Then the MMC/SD/SDIO host controller enters in low-power state (MMCI_ICLK clock autogated) even if MMCI.[MMCHS_SYSCONFIG\[0\]](#) AUTOIDLE is set to 0.

The functional clock is internally switched off and only interconnect read and write accesses are allowed.

Idle Mode

The MMCI_ICLK and MMCI_FCLK clocks provided to MMC/SD/SDIO are switched off upon a PRCM module request. They are switched back upon module request.

The MMC/SD/SDIO host controller complies with the PRCM module handshaking protocol:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller
- Wake-up request from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCI.[MMCHS_SYSCONFIG\[4:3\]](#) SIDLEMODE bit field:

- 0x0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 0x1: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the MMCI_ICLK and MMCI_FCLK clocks may be switched off whatever the value set in the MMCI.[MMCHS_SYSCONFIG\[9:8\]](#) CLOCKACTIVITY field.

Transition From Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCI.[MMCHS_SYSCONFIG\[4:3\]](#) SIDLEMODE bit field is set to 0x2.

The MMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity.

During normal to idle mode transition, any access to the registers of the MMC/SD/SDIOi host controller generates an error as long as the MMCI_ICLK clock is alive. The PRCM.CM_IDLEST1_CORE[25] ST_MMC2 and (respectively the PRCM.CM_IDLEST1_CORE[24] ST_MMC1 bit) is set to 0x0 when the MMC/SD/SDIO2 module (respectively the MMC/SD/SDIO1 module) can be accessed.

The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi/single-block transfer is completed.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on mmci_dat[1] signal.

As long as the MMC/SD/SDIOi controller do not acknowledge the idle request, if an event occurs, the MMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM.

As soon as the MMC/SD/SDIOi controller acknowledges the idle request from the PRCM, the module does not assert any new interrupt or DMA request.

Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when the following enable wake-up bits are set:

- MMCI.MMCHS_SYSCONFIG[2] ENAWAKEUP bit is set to 0x1
- MMCI.MMCHS_HCTL[24] IWE bit is set to 0x1
- MMCI.MMCHS_IE[8] CIRQ_ENABLE bit is set to 0x1

The wakeup is generated only in smart-idle mode only, when module is in idle mode.

Table 24-4 lists the supported cases in smart-idle mode.

Table 24-4. Smart Idle Mode and Wake-Up Capabilities

Mode	MMCI_ICLK clock	MMCI_FCLK clock	Wake-up Event
Card interrupt	May be switched off ⁽¹⁾	May be switched off ⁽¹⁾	The module sends an asynchronous wake-up request on detection of a card interrupt on mmci_dat[1] signal

⁽¹⁾ The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, whatever the value set in the MMCI.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit.

Transition From Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM deasserts the idle request.

For the wake-up event, there is a corresponding interrupt status in the MMCI.MMCHS_STAT register. The MMC/SD/SDIOi host controller operates the conversion between wake-up and interrupt (or DMA request) upon exit from smart-idle mode if the associated enable bit is set in the MMCI.MMCHS_ISE register.

Interrupts and wake-up events have independent enable/disable controls, accessible through the MMCI.MMCHS_HCTL and MMCI.MMCHS_ISE registers. The overall consistency must be ensured by software.

The interrupt status register MMCI.MMCHS_STAT is updated with the event that caused the wake-up in the CIRQ bit when the MMCI.MMCHS_IE[8] CIRQ_ENABLE associated bit is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCI.MMCHS_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM is deasserted, the module switches back to normal mode. The module is fully operational.

Force-Idle Mode

Force-idle mode is enabled when the MMCI.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode where the MMC/SD/SDIOi host controller responds unconditionally to the idle request from the PRCM. Moreover, in this mode, the MMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCI.[MMCHS_STAT](#) register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCI_ICLK and MMCI_FCLK can be switched off.

CAUTION

In force-idle mode, an idle request from the PRCM during a command or a data transfer can lead to an unexpected and unpredictable result.

When the module is idle, any access to the module generates an error as long as the MMCI_ICLK clock is alive.

The module exits the force-idle mode when the PRCM deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

24.3.1.2 Resets

24.3.1.2.1 Hardware Reset

The module is reinitialized by the hardware when the active-low reset signal (CORE_RST), synchronous to the MMCI_ICLK clock is asserted on the input pin MMCI_RESET (see [Chapter 3, Power, Reset, and Clock Management](#) for more information).

A global status bit RESETDONE is provided in the status register MMCI.[MMCHS_SYSSTATUS\[0\]](#). This bit is set to 1 when all the different clock domain resets (interface domain, functional domain, and 32K domain) have been released.

The MMCI.[MMCHS_SYSSTATUS\[0\]](#) RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a hardware reset.

NOTE: Functional clock MMCI_FCLK, interface clock MMCI_ICLK, and debounce clock MMCI_32K must be provided to the module to allow the RESETDONE status bit to be set.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

24.3.1.2.2 Software Reset

The module is reinitialized by software through the MMCI.[MMCHS_SYSCONFIG\[1\]](#) SOFTRESET bit. This bit has the same action on the module logic as the hardware MMCI_RESET signal except for:

- Debounce logic
- MMCI.[MMCHS_PSTATE](#), MMCI.[MMCHS_CAPA](#), and MMCI.[MMCHS_CUR_CAPA](#) registers (see corresponding register descriptions)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by the hardware. The MMCI.[MMCHS_SYSCTL\[24\]](#) SRA bit has the same action as the SOFTRESET bit on the design.

The MMCI.[MMCHS_SYSSTATUS\[0\]](#) RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCI.[MMCHS_SYSCTL\[26\]](#) SRD bit
- MMCI.[MMCHS_SYSCTL\[25\]](#) SRC bit

These two reset bits are useful to reinitialize data or command processes respectively in case of line conflict. When set to 1, a reset process is automatically released when the reset completes:

- The MMCI.[MMCHS_SYSCTL](#)[26] SRD bit resets all finite state-machines and status management that handle data transfers on both the interface and functional side.
- The MMCI.[MMCHS_SYSCTL](#)[25] SRC bit resets all finite state-machines and status management that handle command transfers on both the interface and functional side.

24.3.1.3 Power Domain

MMC/SD/SDIOi power is supplied by the CORE power domain (see [Chapter 3, Power Reset and Clock Management](#) for more information).

When the MMC/SD/SDIOi power domain is off, the only way to wake up the power domain and different MMC/SD/SDIOi clocks is to monitor mmci_dat[1] input pin state via a different GPIO line for each MMC/SD/SDIO interface (see [Chapter 25, General-Purpose Interface](#), for more information).

24.3.2 Hardware Requests

24.3.2.1 DMA Requests

The MMC/SD/SDIOi host controller can be interfaced with a DMA controller. At system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards as specified in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00.

The DMA request is issued if the three following conditions are met:

- The MMCI.[MMCHS_CMD](#)[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the mmci_cmd line.
- There is enough space in the buffer of the MMC/SD/SDIOi host controller to write an entire block (BLEN writes).

DMA request lines are connected on the system DMA (sDMA) inputs:

- S_DMA_60 (MMC1_DMA_TX)
- S_DMA_61 (MMC1_DMA_RX)
- S_DMA_46 (MMC2_DMA_TX)
- S_DMA_47 (MMC2_DMA_RX)
- S_DMA_76 (MMC3_DMA_TX)
- S_DMA_77 (MMC3_DMA_RX)

24.3.2.1.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal MMCI_DMA_RX is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCI.[MMCHS_BLK](#)[10:0] BLEN field.

The MMCI_DMA_RX signal is deasserted to its inactive level when the sDMA has read one single word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. As DMA accesses are in 32-bit, then the number of sDMA read is Integer(BLEN/4)+1.

The receive buffer never overflows. In multiple block transfers for block size above 512 bytes, when the buffer gets full, the mmci_clk clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

Summary (see [Figure 24-18](#)):

- DMA transfer size = BLEN buffer size (maximum 1024 32-bit words) in one shot or by burst
- One DMA request per block

Figure 24-18. DMA Receive Mode

mmchs-018

24.3.2.1.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal MMCI_DMA_TX is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the MMCI.**MMCHS_BLK[10:0]** BLEN field.

The MMCI_DMA_TX signal is deasserted to its inactive level when the sDMA has written one single word to the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (as DMA accesses are in 32-bit, then the number of sDMA read is Integer(BLEN/4)+1) and if there is not enough memory space to write a complete block in the buffer.

Summary (see [Figure 24-19](#)):

- DMA transfer size = BLEN buffer size (maximum 1024 32-bit words) in one shot or by burst
- One DMA request per block

Figure 24-19. DMA Transmit Mode

mmchs-019

24.3.2.2 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCI.MMCHS_STAT register; it indicates which service is required.
- The interrupt status enable bits of the MMCI.MMCHS_IE register enable/disable the automatic update of the MMCI.MMCHS_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the MMCI.MMCHS_ISE register enable/disable the transmission of an interrupt request on the interrupt line MMCI_IRQ (from the MMC/SD/SDIOi host controller to the MPU subsystem interrupt controller) on an event-by-event basis.

If an interrupt status is disabled in the MMCI.MMCHS_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCI.MMCHS_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the MMC/SD/SDIOi host controller updates the status bit) in the MMCI.MMCHS_STAT register. If later a mask is applied on the interrupt in the MMCI.MMCHS_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCI.MMCHS_STAT register and the corresponding mask is removed from the MMCI.MMCHS_ISE register, the interrupt status is not asserted again in the MMCI.MMCHS_STAT register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

CAUTION

If the buffer write ready interrupt (BWR) or the buffer read ready only interrupt (BRR) are not serviced and are cleared in the MMCi.[MMCHS_STAT](#) register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller will wait for the service of the interrupt without updating the status MMCi.[MMCHS_STAT](#) or transmitting an interrupt request.

The MMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

There are one interrupt line for each instance of the MMC/SD/SDIOi host controller:

- MMC1_IRQ is connected to M_IRQ_83 for MMC/SD/SDIO1 instance.
- MMC2_IRQ is connected to M_IRQ_86 for MMC/SD/SDIO2 instance.
- MMC3_IRQ is connected to M_IRQ_94 for MMC/SD/SDIO3 instance.

24.3.2.2.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the MMCi.[MMCHS_IE](#) register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

- Read the MMCi.[MMCHS_STAT](#) register to identify which event occurred.
- Write 1 into the corresponding bit of the MMCi.[MMCHS_STAT](#) register to clear the interrupt status and release the interrupt line (if a read is done after this write, this would return 0).

NOTE: In the MMCi.[MMCHS_STAT](#) register, Card Interrupt (CIRQ) and Error Interrupt (ERRI) bits cannot be cleared.

The MMCi.[MMCHS_STAT](#)[8] CIRQ status bit must be masked by disabling the MMCi.[MMCHS_IE](#)[8] CIRQ_ENABLE bit (set to 0x0), then the interrupt routine must clear SDIO interrupt source in SDIO card common control register (CCCR). See [Chapter 9, Interconnect](#) for more information.

The MMCi.[MMCHS_STAT](#)[15] ERRI bit is automatically cleared when all status bits in MMCi.[MMCHS_STAT](#)[31:16] are cleared.

24.3.2.2.2 Polling

When the interrupt capability of an event is disabled in the MMCi.[MMCHS_ISE](#) register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.[MMCHS_STAT](#) register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.[MMCHS_STAT](#) register clears the interrupt status and does not affect the interrupt line state.

NOTE: See the previous note concerning CIRQ and ERRI bits clearing.

24.4 MMC/SD/SDIO Functional Description

24.4.1 Description

MMC/SD/SDIOi host controller is partitioned into two clock domains:

- The interface L4 clock domain
- The functional clock domain

Any two domains are considered asynchronous to each other, and exchanges between the two domains are synchronized through a synchronization stage and an asynchronous buffer. Data are transferred from one domain to other through the buffer (2*512 RAM).

[Figure 24-20](#) shows a block diagram of the MMC/SD/SDIO host controller.

Figure 24-20. MMC/SD/SDIO Diagram

In the L4 clock domain, the user can:

- Control the transfer (configure parameters for the transfer)
- Control clock activities and reset
- Manage interrupts and hardware requests
- Consult different status:
 - Bus
 - Buffer
 - Interrupts
 - Errors
- Transmit and receive data through the buffer

In the functional clock domain, the internal mechanisms perform the transfers of data and commands.

For more detail see the command response registers (MMCi.MMCHS_RSPn registers: [Table 24-53](#), [Table 24-55](#), [Table 24-57](#), and [Table 24-59](#)).

CAUTION

Read access to the command response registers is allowed only when the command process is completed.

24.4.2 Mode Selection

The MMC/SD/SDIO host controller can be used in two modes: MMC and SD/SDIO modes. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each given card type, there are corresponding commands. Some commands are not supported by all cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, and the *SDIO Card Specification, Part E1*, v1.10, for more details.

The purpose of the module is to transfer commands and data, to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

24.4.3 Buffer Management

24.4.3.1 Data Buffer

The MMC/SD/SDIOi host controller uses a data buffer divided into two 512-byte portions that are 32 bits wide by 128 words deep. This buffer transfers data from one data bus (Interconnect) to another data bus (SD/SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (L4 and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than the one of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer for the two portions, the prefetch buffer and the post-write buffer, is the 32-bit register MMCi.[MMCHS_DATA](#). A write access to the MMCi.[MMCHS_DATA](#) register followed by a read access from the MMCi.[MMCHS_DATA](#) register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the MMCi.[MMCHS_DATA](#) register and the data of the read access to the MMCi.[MMCHS_DATA](#) register are different.

The number of 32-bit accesses to the MMCi.[MMCHS_DATA](#) register that are needed to read (or write) a data block with a size of MMCi.[MMCHS_BLK](#)[10:0] BLEN, and equals the rounded up result of BLEN divided by 4.

The maximum block size supported by the host controller is 1024 bytes. This value is hard-coded in the register MMCi.[MMCHS_CAPA](#)[17:16] MBL field and cannot be changed.

A read access to the MMCi.[MMCHS_DATA](#) register is allowed only when the buffer read enable status is set to 1 (MMCi.[MMCHS_PSTATE](#)[11] BRE); otherwise, a bad access (MMCi.[MMCHS_STAT](#)[29] BADA) is signaled.

A write access to the MMCi.[MMCHS_DATA](#) register is allowed only when the buffer write enable status is set to 1 (MMCi.[MMCHS_PSTATE](#)[10] BWE); otherwise, a bad access (MMCi.[MMCHS_STAT](#)[29] BADA) is signaled and the data is not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to 512 bytes, meaning the value written in BLEN is less than or equal to 0x200, two data transfers can occur from one data bus to the other data bus and vice versa at the same time. The MMC/SD/SDIOi host controller uses the two portions of the data buffer in a ping pong manner so that storing and reading of the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) is being stored into the other portion and vice versa. When BLEN is less than, or equal to 0x200 (that is, less than, or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32 bits x BLEN div by 4). Do not use a size greater than 2 times this value.

CAUTION

The MMCi.[MMCHS_CMD](#)[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 24-21 and Figure 24-22 show the buffer management for a write and for a read, respectively.

Figure 24-21. Buffer Management for a Write

mmchs-047

Figure 24-22. Buffer Management for a Read

mmchs-043

- When the size of the data block to transfer is larger than 512 bytes, meaning the value written in BLEN is 0x201 or larger, only one data transfer can occur from one data bus to the other data bus at a time. The MMC/SD/SDIOi host controller uses the entire data buffer as a single 1024-byte portion. In this mode, a bad access (MMCi.MMCHS_STAT[29] BADA) is signaled when two data transfers occur from one data bus to the other data bus and vice versa at the same time.

24.4.3.1.1 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers (see Table 24-69):
 - MMCi.MMCHS_STAT[29] BADA: Bad access to data space
 - MMCi.MMCHS_STAT[5] BRR: Buffer read ready
 - MMCi.MMCHS_STAT[4] BWR: Buffer write ready
- Status registers (see Table 24-63):
 - MMCi.MMCHS_PSTATE[11] BRE: Buffer read enable
 - MMCi.MMCHS_PSTATE[10] BWE: Buffer write enable

24.4.4 Transfer Process

The process of a transfer is dependent on the type of command. It can be with or without a response, with or without data.

24.4.4.1 Different Types of Commands

Different types of commands are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, the *SDIO Card Specification, Part E1*, v1.10, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, for more details.

24.4.4.2 Different Types of Responses

Different types of responses are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, the *SDIO Card Specification, Part E1*, v1.10, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, for more details.

[Table 24-5](#) shows how the MMC, SD, and SDIO responses are stored in the MMCHS_RSPxx registers.

Table 24-5. MMC, SD, SDIO responses in the MMCHS_RSPxx registers

Kind of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6	RESP[39:8] ⁽¹⁾	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response)	RESP[39:8] ⁽¹⁾	MMCHS_RSP76[31:0]
R2	RESP[127:0] ⁽¹⁾	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

⁽¹⁾ RESP refers to the command response format described in the specifications mentioned above.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the [MMCHS_RSP76\[31:0\]](#) register because the Host Controller may have a multiple block data DAT line transfer executing concurrently with a command. This allows the host controller to avoid overwriting the Auto CMD12 response with the command response stored in [MMCHS_RSP10](#) register and vice versa.

24.4.5 Transfer or Command Status and Error Reporting

Flags in the MMC/SD/SDIOi host controller show status of communication with the card:

- A timeout (of a command, a data, or a response)
- A CRC

Error conditions generate interrupts. See [Table 24-6](#) and register description for more details.

Table 24-6. CC and TC Values Upon Error Detected

Error hold in the MMCI.MMCHS_STAT register	CC	TC	Comments
29	BADA		No dependency with CC nor TC BADA is related to MMCHS_DATA register accesses. Its assertion is not dependent of the ongoing transfer.
28	CERR	1	CC is set upon CERR.
22	DEB	1	TC is set upon DEB.
21	DCRC	1	TC is set upon DCRC.
20	DTO		DTO and TC are mutually exclusive DCRC and DEB cannot occur with DTO.
19	CIE	1	CC is set upon CIE.

Table 24-6. CC and TC Values Upon Error Detected (continued)

Error hold in the MMCI.MMCHS_STAT register	CC	TC	Comments
18	CEB	1	CC is set upon CEB.
17	CCRC	1	CC can be set upon CCRC - See CTO comment
16	CTO		CTO and CC are mutually exclusive. CIE, CEB and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: it indicates a command abort due to a contention on CMD line. In this case no CC appears.

MMCHS_STAT[21] DCRC event can be asserted in the following conditions:

- busy timeout for R1b, R5b response type
- busy timeout after write CRC status
- write CRC status timeout
- read data timeout
- boot acknowledge timeout

24.4.5.1 Busy Timeout For R1b, R5b Response Type

Figure 24-23 shows DCRC event condition asserted when there is busy timeout for Rb1, R5b response.

Figure 24-23. Busy Timeout for R1b, R5b Response Type

t1 - Data timeout counter is loaded and starts after R1b, R5b response type

t2 - Data timeout counter stops and if it is 0, **MMCHS_STAT[21]** DCRC is generated.

24.4.5.2 Busy Timeout After Write CRC Status

Figure 24-24 shows DCRC event condition asserted when there is busy timeout after write CRC status.

Figure 24-24. Busy Timeout After Write CRC Status

mmchs-057

t1 - Data timeout counter is loaded and starts after CRC Status

t2 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.

24.4.5.3 Write CRC Status Timeout

Figure 24-25 shows DCRC event condition asserted when there is write CRC status timeout.

Figure 24-25. Write CRC Status Timeout

mmchs-058

t1 - Data timeout counter is loaded and starts after Data block + CRC

t2 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.

24.4.5.4 Read Data Timeout

Figure 24-26 shows DCRC event condition asserted when there is read data timeout.

Figure 24-26. Read Data Timeout

mmchs-059

- t1 - Data timeout counter is loaded and starts after Command transmission.
- t2 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.
- t3 - Data timeout counter is loaded and starts after Data block + CRC transmission.
- t4 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.

24.4.5.5 Boot Acknowledge Timeout

[Figure 24-28](#) shows DCRC event condition asserted when there is boot acknowledge timeout and CMD0 is used.

Figure 24-27. Boot Acknowledge Timeout When Using CMD0

* Refer to MMC specification for correct argument.

mmchs-060

- t1 - Data timeout counter is loaded and starts after CMD0.
- t2 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.
- t3 - Data timeout counter is loaded and starts.
- t4 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.
- t5 - Data timeout counter is loaded and starts after Data + CRC transmission.
- t6 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.

[Figure 24-28](#) shows DCRC event condition asserted when there is boot acknowledge timeout and CMD0 is used.

Figure 24-28. Boot Acknowledge Timeout When CMD Line Tied To 0

- t1 - Data timeout counter is loaded and starts after cmd line is tied to 0.
- t2 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[DCRC\]](#) is generated.
- t3 - Data timeout counter is loaded and starts.
- t4 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[DCRC\]](#) is generated.
- t5 - Data timeout counter is loaded and starts after Data + CRC transmission.
- t6 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[DCRC\]](#) is generated.

24.4.6 Autocommand 12 Timings

With the UHS definition of SD cards with higher frequency for MMC clock up to 208, SD standard imposes a specific timing for Auto CMD12 'end bit' arrival.

24.4.6.1 Autocommand 12 Timings During Write Transfer

A margin named Ncrc in range of 2 to 8 cycles has been defined for SDR50 and SDR104 card components for write data transfers, as autocommand 12 'end bit' shall arrive after the CRC status 'end bit'.

[Figure 24-29](#) shows auto CMD12 timings during write transfer.

Figure 24-29. Autocommand 12 Timings During Write Transfer

The Host controller has a margin of 18 clock cycles to make sure that auto CMD12 'end bit' arrives after the CRC status. This margin does not depend on MMC bus configuration, DDR or standard transfer, 1,4 or 8 bus width.

24.4.6.2 Autocommand 12 Timings During Read Transfer

With UHS very high speed cards gap timing between 2 successive cards has been extended to 4 cycles instead of 2. By the way it gives more flexibility for Host Auto CMD12 arrival in order to receive the last complete and reliable block. MMCHS controller only follows the 'Left Border Case' defined by SD UHS specification.

Figure 24-30 shows ACMD12 timings during read transfer.

Figure 24-30. Autocommand 12 Timings During Read Transfer

mmchs-063

The Auto CMD12 arrival sent by the Host controller is not sensitive to the MMC bus configuration whether it is DDR or standard transfer and whether it is a 1,4 or 8 bit bus width transfer.

24.4.7 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop whereas it is still not finished. Several cases can be faced depending on the transfer type:

- Multiple blocks oriented transfers (for which transfer length is known)
- Continuous stream transfers (which have an infinite length)

NOTE: Since the MMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer will accept a block only if there is enough space to completely store it. Consequently, if a block is pending in the buffer, no command will be sent to the card because the card clock will be shut off by the controller.

The MMC/SD/SDIOi controller includes two features which makes a transfer stop more convenient and easier to manage:

- Auto CMD12 (for MMC and SD only).

This feature is enabled by setting the MMC_i.MMCHS_CMD[2] ACEN bit to 0x1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12 feature is enabled, the MMC/SD/SDIOi controller will automatically issue a CMD12 command when the expected number of blocks has been exchanged.

- Stop at block gap

This feature is enabled by setting the MMC_i.MMCHS_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

NOTE: For MMC and SD cards, the stop at block gap feature is not supported in READ mode.

For SDIO cards, this setting can be supported in READ mode if the card has a read wait capability.

Table 24-7 shows the common way to stop a transfer, indicating command to send and features to enable.

Table 24-7. MMC/SD/SDIOi Controller Transfer Stop Command Summary

		WRITE transfer		READ transfer	
		SD / MMC	SDIO	SD / MMC	SDIO
Single block		Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC
Multi blocks (finite or infinite)	Before the programmed block boundary	Send CMD12 Wait TC	Send CMD52 Wait TC	Send CMD12 Wait TC	Send CMD52 Wait TC
	Stop at the end of the transfer (finite transfer only)	Auto CMD12 active Transfer ends automatically Wait TC	Set MMCI.MMCHS_HC TL[16] SBGR bit to 0x1. Send CMD52 Wait TC	Auto CMD12 active Transfer ends automatically Wait TC	If READ_WAIT supported Stop at block gap Wait TC
				If READ_WAIT not supported Send CMD52 Wait TC	

NOTE: The MMC/SD/SDIOi controller will send the stop command to the card on a block boundary, regardless the moment the command was written to the controller registers.

24.4.8 MMC CE-ATA Command Completion Disable Management

The MMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal ([MMCHS_CON\[12\]](#) CEATA and [MMCHS_CMD\[2\]](#) ACEN set to 1) is launched, host system is no longer allowed to emit a new command in parallel of data transfer unless it is a command completion disable.

The settings to emit a command completion disable token follow:

- [MMCHS_CON\[12\]](#) CEATA is set to 1.
- [MMCHS_CON\[2\]](#) HR set to 1.
- Clear the [MMCHS_ARG](#) register.
- Write into [MMCHS_CMD](#) register with value 0x00000000.

When a command completion disable token was emitted (that is, [MMCHS_STAT\[0\]](#) CC received), the host system is again allowed to emit another type of command (for example a transfer abort command CMD12 to abort transfer).

A critical case can be met when command completion signal disable (CCSD) is emitted during the last data block transfer, the sequence on command line could be sent very close to command completion signal (CCS) token sent by the card.

Three cases can be met:

- CCS is receive just before CCSD is emitted:
An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to card then an interrupt CC is generated when CCSD ends. In this case, card consider the CCSD sequence.
- CCS is not generated or generated during the CCSD transfer:
The CCS bit cannot be detected (conflict is not possible as they drive the same level on command line, then no CIRQ interrupt is generated; besides CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:

Only the interrupt CIRQ is generated when CCS is detected.

24.5 MMC/SD/SDIO Basic Programming Model

24.5.1 MMC/SD/SDIO Host Controller Initialization Flow

Figure 24-31 shows the general boot process.

Figure 24-31. MMC/SD/SDIO Controller Meta Initialization Steps

mmchs-024

24.5.1.1 Enable Interface and Functional clock for MMC Controller

Prior to any MMCHS register access one must enable MMCHS interface clock and functional clock in PRCM module registers PRCM.CM_ICLKEN1_CORE and PRCM.CM_FCLKEN1_CORE. See [Chapter 3, Power, Reset, and Clock Management](#).

24.5.1.2 MMCHS Soft Reset Flow

Figure 24-32 shows the soft reset process of MMCHS controller.

Figure 24-32. MMC/SD/SDIO Controller Software Reset Flow

mmchs-025

24.5.1.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM for instance) and is allowed to set (write) MMCI.**MMCHS_CAPA**[26:24] and MMCI.**MMCHS_CUR_CAPA**[23:0] registers before the MMC/SD/SDIO host driver is started.

24.5.1.4 Wake-Up Configuration

Figure 24-33 details MMCHS controller wake-up configuration.

Figure 24-33. MMC/SD/SDIO Controller Wake-Up Configuration

mmchs-027

24.5.1.5 MMC Host and Bus Configuration

Figure 24-34 details MMC bus configuration process.

Figure 24-34. MMC/SD/SDIO Controller Bus Configuration

mmchs-028

24.5.2 Basic Operations for MMC/SD/SDIO Host Controller

The MMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis, rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

24.5.2.1 Card Detection, Identification, and Selection

Figure 24-35 and Figure 24-36 show the card identification and selection process.

Figure 24-35. MMC/SD/SDIO Controller Card Identification and Selection - Part 1

24.5.2.2 Read/Write Transfer Flow in DMA Mode With Interrupt

Figure 24-37 describes the read and write protocol in DMA mode with interrupt signaling. See Chapter 11, SDMA, for more information on the DMA settings.

Figure 24-37. MMC/SD/SDIO Controller Read/Write Transfer Flow in DMA Mode With Interrupt

24.5.2.3 Read/Write Transfer Flow in DMA Mode With Polling

Figure 24-38 describes the read and write protocol in DMA mode. See [Chapter 11, SDMA](#), for more information on the DMA settings.

Figure 24-38. MMC/SD/SDIO Controller Read/Write Transfer Flow in DMA Mode With Polling

mmchs-033

24.5.2.4 Read/Write Transfer Flow Wthout DMA and With Polling

Figure 24-39 describes a read/write transfer without using the DMA and with polling.

Figure 24-39. MMC/SD/SDIO Controller Read/Write Transfer Flow Without DMA and With Polling

mmchs-034

24.5.2.5 Read/Write Transfer Flow in CE-ATA Mode

Figure 24-40 describes the read and write CE-ATA protocol when in Polling mode.

Figure 24-40. MMC/SD/SDIO Controller Read/Write in CE-ATA Mode

mmchs-037

CAUTION

CE-ATA protocol is only supported by MMC cards.

In CE-ATA mode, issuing command during the transfer (except a CCSD command) is not allowed

In CE-ATA mode, infinite transfers are not allowed, only finite transfers are permitted.

24.5.2.6 Suspend-Resume Flow

The suspend and resume feature is only supported by SDIO cards.

24.5.2.6.1 Suspend Flow

Figure 24-41 describes the suspend flow for SDIO cards.

Figure 24-41. MMC/SD/SDIO Controller Suspend Flow

mmchs-038

24.5.2.6.2 Resume Flow

Figure 24-42 describes the resume flow for SDIO cards.

Figure 24-42. MMC/SD/SDIO Controller Resume Flow

mmchs-039

24.5.2.7 Basic Operations - Step Details

24.5.2.7.1 Command Transfer Flow

Figure 24-43 describes how to send a command to the card using polling instead of interrupts for event signaling.

Figure 24-43. MMC/SD/SDIO Controller Command Transfer Flow With Polling

mmchs-040

Figure 24-44 describes how to send a command to the card using interrupts for event signaling.

Figure 24-44. MMC/SD/SDIO Controller Command Transfer Flow With Interrupts

24.5.2.7.2 MMC/SD/SDIO Clock Frequency Change

Figure 24-45 describes the different steps that allow to change the MMC/SD/SDIO output clock frequency.

Figure 24-45. MMC/SD/SDIO Controller Clock Frequency Change Flow

mmchs-042

24.5.3 MMC/SD/SDIO1 Bus Voltage Selection

The MMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.0 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns those pads must have an internal bias voltage reference to operate. The PBIAS_LITE module supplies this bias voltage, depending on the CONTROL.CONTROL_PBIAS_LITE register settings.

See [Section 13.4.5, Extended-Drain I/O Pin and PBIAS Cell](#), for more information about the PBIAS_LITE cell.

[Section 13.5.2, Extended-Drain I/Os and PBIAS Cell Basic Programming Guide](#), describes the steps involved in transitioning from 1.8 V to 3.0 V and from 3.0 V to 1.8 V, applicable to the MMC/SD/SDIO1 controller.

CAUTION

The BIAS voltage must be set using the procedure described in [Section 13.5.2, Extended-Drain I/Os and PBIAS Cell Basic Programming Guide](#). Failure to follow this procedure can damage the MMCHS interface.

[Figure 24-46](#) describes how to configure the MMCHS controller to fit with power switching sequence.

Figure 24-46. MMC/SD/SDIO Power Switching Procedure

mmchs-055

24.6 MMC/SD/SDIO Use Cases and Tips

24.6.1 MMCHS Controller Usage

24.6.1.1 Overview

The MMCHS controller is in charge of managing raw data storage in a MMC memory card. The MMCHS controller transfers data between DDRAM and MMC card. [Figure 24-47](#) gives an overview of MMCHS controller position in the use case.

Figure 24-47. Overview

mmchs_050

For the Camcorder use case, the MMCHS controller is configured to operate with the following features :

- High speed mode with a card clock frequency of 48 MHz.
- 4 data lines.
- 1.8 V and 3.0 V voltage capabilities.

MMC card power supply is not provided by the MMCHS controller itself but rather by the companion device. See [Chapter 17](#) to learn how to set these voltage levels.

Only MMC1 controller is used in this configuration. Hence this document describes the output of the test carried out with MMC1 controller.

24.6.1.2 Environment

To operate in the correct manner, the MMCHS controller needs the System Control Module (SCM) to be configured with the right muxing mode and with the right pull up state. The MMC card needs to be powered with the right power level and this is done with the companion device. [Figure 24-48](#) gives the environment picture of the MMCHS controller.

Figure 24-48. Environment

24.6.1.2.1 Command and Data Transfer Formats

When communicating with a MMC card, The MMCHS controller is always the master. The communication between the MMCHS controller and the MMC card always starts by sending a command. Both command and data transfers are started with a command.

The data transfer type used by the MMCHS controller is a finite multiple block transfer. [Figure 24-49](#) illustrates a command transfer without data. [Figure 24-50](#) and [Figure 24-51](#) illustrate a multiple block transfer between the MMCHS controller and the MMC card.

Figure 24-49. Command Transfer

mmchs_052

Figure 24-50. Data Read Transfer

mmchs_053

Figure 24-51. Data Write Transfer

mmchs_054

24.6.1.3 Programming Flow

24.6.1.3.1 Initial Configuration

The initialization of the MMCHS controller is done through these steps :

1. MMCHS controller interface and functional clocks enabling.
2. MMCHS controller software reset.
3. MMCHS controller voltage capabilities initialization.
4. MMCHS controller default initialization.
5. MMCHS controller INIT procedure start.

6. MMCHS controller pre-card identification configuration.

For more information about different steps the MMCHS controller goes through during initial configuration see [Section 24.5, MMC/SD/SDIO Basic Programming Model](#).

24.6.1.3.1.1 MMCHS Controller Interface and Functional Clocks Enabling

In order to enable the interface and functional clocks of the MMCHS1 controller, the following steps must be done:

1. Enable the interface clock for the MMCHS1 controller (set the PRCM.CM_ICLKEN1_CORE[24] EN_MMCHS1).
2. Enable the functional clock for the MMCHS1 module (set the PRCM.CM_FCLKEN1_CORE[24] EN_MMCHS1).

[Table 24-8](#) shows all PRCM registers to be configured to enable interface and functional clocks for MMCHS1 controller.

Table 24-8. Register Print for the MMCHS1 Controller Clock Initialization

Register Name	Register Address	Value	Value Description
PRCM.CM_ICLKEN1_CORE	0x4800 4A10	0x01000000	MMCHS1 interface clock enabled
PRCM.CM_FCLKEN1_CORE	0x4800 4A00	0x01000000	MMCHS1 functional clock enabled

24.6.1.3.1.2 MMCHS Controller Software Reset

To software-reset the MMCHS1 controller, the following steps must be performed:

1. Write 0x2 in MMCHS1.[MMCHS_SYS CONFIG](#) register.
2. Wait until MMCHS1.[MMCHS_SYS STATUS](#)[0] RESETDONE turns 1.

[Table 24-9](#) describes the software-reset registers.

Table 24-9. Software-Reset Register Description

Register Name	Register Address	Value	Value Description
MMCHS1. MMCHS_SYS CONFIG	0x4809 C010	0x00000002	Activate software reset.
MMCHS1. MMCHS_SYS STATUS	0x4809 C014	0x00000001	Reset is over.

24.6.1.3.1.3 MMCHS Controller Voltage Capabilities Initialization

MMCHS1 controller's voltage capabilities should be set in MMCHS1.[MMCHS_CAPA](#). See [Table 24-10](#).

Table 24-10. MMCHS Controller Voltage Capabilities Initialization

Register Name	Register Address	Value	Value Description
MMCHS1. MMCHS_CAPA	0x4809 C140	current_value 0x06000000	Activate VS18 and VS30 in the MMCHS_CAPA register.

24.6.1.3.1.4 MMCHS Controller Default Initialization

Before sending any command, the MMCHS controller is configured with default values:

1. Default voltage support is set to 1.8 V in MMCHS1.[MMCHS_HCTL](#)[11:9] SDVS.
2. MMC bus is set to open drain in MMCHS1.[MMCHS_CON](#)[0] OD.
3. MMC data bus width is set to 1 in MMCHS1.[MMCHS_HCTL](#)[1] DTW.
4. MMC Card's power is off.
5. MMC card's clock is on in MMCHS1.[MMCHS_SYS CTL](#)[0] ICE and MMCHS1.[MMCHS_SYS CTL](#)[2] CEN.
6. MMCHS controller bus power up in MMCHS1.[MMCHS_HCTL](#)[8] SDBP.

7. MMC card's clock frequency is set to 150 kHz in MMCHS1.[MMCHS_SYSCTL\[15:6\]](#) CLKD.

[Table 24-11](#) shows the values that must be written in the right register pool.

Table 24-11. MMC Controller Default Initialization Values

Register Name	Register Address	Value	Value Description
MMCHS1. MMCHS_HCTL	0x4809C128	0x00000b00	data bus width = 1, voltage = 1.8 V, MMC bus power is on (not card's power)
MMCHS1. MMCHS_SYSCTL	0x4809C12C	0x0000a007	card's clock enable and card's clock frequency divider
MMCHS1. MMCHS_CON	0x4809C02C	0x00000001	Set MMC bus mode to open-drain.

A small notice about MMCHS1.[MMCHS_HCTL](#). Even if the value written in it is 0x00000b00, the value read from it is equal to 0x00000a00. This is due to the fact that the MMCHS controller is not in a card state mode which sets automatically the [MMCHS_HCTL\[8\]](#) SDBP bit to 0.

24.6.1.3.1.5 MMCHS Controller INIT Procedure Start

Prior to issuing any command, the MMCHS controller has to execute a special INIT procedure. The MMCHS controller has to generate a clock during 1ms. During the INIT procedure, the MMCHS controller generates 80 clock periods. In order to keep the 1 ms gap, the MMCHS controller should be configured to generate a clock whose frequency is smaller or equal to 80 kHz.

The INIT procedure is executed by setting MMCHS1.[MMCHS_CON\[1\]](#) INIT bit field to 1 and by sending a dummy command, writing 0x00000000 in the MMCHS1.[MMCHS_CMD](#) register.

To assure the synchronous clock on the clock output of the MMC1 controller, set the CONTROL.CONTROL_PADCONF_MMC1_CLK[8] bit. In this way, the clock output is also configured as input and the result is looped back through the output and input buffers of the pad.

[Table 24-12](#) shows the values that should be written in the right register pool.

Table 24-12. MMCHS Controller INIT Procedure Start

Register Name	Register Address	Value	Value Description
MMCHS1. MMCHS_CON	0x4809C02C	current_value 0x00000002	Sets MMCHS1. MMCHS_CON[1] INIT to 1
MMCHS1. MMCHS_CMD	0x4809C10C	0x00000000	Sends dummy command.
CONTROL.CONTROL_PADCO_NF_MMC1_CLK	0x4800 2144	0x100	Set the INPUTENABLE bit to assure the synchronous clock.

24.6.1.3.1.6 MMCHS Controller Precard Identification Configuration

Before card identification starts, the MMCHS controller's configuration should change. The MMC card's clock should now be 400 kHz, according to the MMC system spec requirements. [Table 24-13](#) shows the values that should be written in the right register pool.

Table 24-13. MMCHS Controller Precard Identification Configuration

Register Name	Register Address	Value	Value Description
MMCHS1. MMCHS_HCTL	0x4809C128	0x00000b00	Data bus width = 1, voltage = 1.8 V, MMC bus power is on (not power of card)
MMCHS1. MMCHS_SYSCTL	0x4809C12C	0x00003C07	Card's clock enable and card's clock frequency divider
MMCHS1. MMCHS_CON	0x4809C02C	0x00000001	Set MMC bus mode to open drain.

24.6.1.3.2 MMC Card Identification

MMC card identification is performed by issuing many MMC commands. Each command imposes certain configuration values in a pool of registers. The status of command transfer is read in MMCHS1.MMCHS_STAT register and command response if any is read from MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54 and MMCHS1.MMCHS_RSP76.

This TRM output describes a use case where interrupts are used to signal MMCHS controller status changes.

For more details about the card identification sequence, see [Section 24.5, MMC/SD/SDIO Basic Programming Model](#).

24.6.1.3.2.1 Sending CMD0

This command resets the MMC card (see [Table 24-14](#)).

Table 24-14. Sending CMD0

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00040001	Enables CC and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00040001	Enables CC and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x00000000	Sends CMD0 whose opcode is 0.

24.6.1.3.2.2 Sending CMD5

This command asks a SDIO card to send its operating conditions (see [Table 24-15](#)). This command will fail if there is no SDIO card. In case of success the response will be in MMCHS1.MMCHS_RSP10 register.

Table 24-15. Sending CMD5

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00050001	Enables CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00050001	Enables CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x05020000	Sends CMD5 whose opcode is 5 and response type is 48 bits.

24.6.1.3.2.2.1 Sending CMD8

This command asks a SD card version 2.X to send its operating conditions (see [Table 24-16](#)). This command will fail if there is no SD card verison 2.X. In case of success the response will be in MMCHS1.MMCHS_RSP10 register.

Table 24-16. Sending CMD8

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x81a0000	Sends CMD8 whose opcode is 8, response type is 48 bits with CICE and CCCE enabled.

24.6.1.3.2.3 Sending CMD55

This is a special command used to prevent the card that the following command is going to be an application one (see [Table 24-17](#)). This is used to prepare the issuing of ACMD41 (opcode = 41) that usually asks a SD card version 1.X to send its operating conditions. If no SD card version 1.X is connected to the MMCHS controller this command will fail. In case of success the response will be received in the MMCHS1.[MMCHS_RSP10](#) register.

Table 24-17. Sending CMD55

Register Name	Register Address	Value	Value Description
MMCHS1. MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1. MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1. MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1. MMCHS_CMD	0x4809C10C	0x371a0000	Sends CMD55 whose opcode is 55, response type is 48 bits with CICE and CCCE enabled.

24.6.1.3.2.4 Sending CMD1

Once the card response is available in register MMCHS1.[MMCHS_RSP10](#), the software is responsible to compare Card OCR and Host OCR, and then send a second CMD1 command with the cross-checked OCR.

This way, the card is notified of the Operating Voltage to work with.

Table 24-18. Sending CMD1

Register Name	Register Address	Value	Value Description
MMCHS1. MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1. MMCHS_IE	0x4809C134	0x00050001	Enables CC, CTO and CEB events to occur.
MMCHS1. MMCHS_ISE	0x4809C138	0x00050001	Enables CC, CTO and CEB interrupts to rise.
MMCHS1. MMCHS_CMD	0x4809C10C	0x01020000	Sends CMD1 whose opcode is 1 and response type is 48 bits.

Once the card response is available in register MMCHS1.[MMCHS_RSP10](#), the software should compare card OCR and host OCR, and then send a second CMD1 command with the cross-checked OCR. This tells the card what operating voltage to use.

24.6.1.3.2.5 Sending CMD2

This command asks the MMC card to send its CID register's content (see [Table 24-19](#)). The response is 128 bits wide and is received in the MMCHS1.[MMCHS_RSP10](#), MMCHS1.[MMCHS_RSP32](#), MMCHS1.[MMCHS_RSP54](#) and MMCHS1.[MMCHS_RSP76](#) registers.

Table 24-19. Sending CMD2

Register Name	Register Address	Value	Value Description
MMCHS1. MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1. MMCHS_IE	0x4809C134	0x00070001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1. MMCHS_ISE	0x4809C138	0x00070001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1. MMCHS_CMD	0x4809C10C	0x02090000	Sends CMD2 whose opcode is 2, response type is 136 bits with CCCE enabled.

24.6.1.3.2.6 Sending CMD3

This command sets the MMC card address (see [Table 24-20](#)). Useful when the MMCHS controller switches to addressed mode.

Table 24-20. Sending CMD3

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x031a0000	Sends CMD3 whose opcode is 3, response type is 48 bits with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

24.6.1.3.3 MMC Bus Setting Change After Card Identification

After the CMD3 command transfer is completed successfully, an auto-negotiation on voltage value starts. This is the frontier when the MMCHS controller should switch from identification mode to transfer mode. This impacts the controller in a way that it should change its bus state from open drain to push-pull. [Table 24-21](#) gives several registers and their values.

Table 24-21. MMC Bus Setting Change Table

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	Bus is now in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000B00	Bus power is on, 1.8 V is selected.
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x000003C07	The internal clock of the MMCHS controller is stable and enabled, and the MMC card clock is on. The divider value is 240, which means the MMCHS controller is still supplying a 400-kHz clock.

24.6.1.3.4 Reading the CSD Register of an MMC Card

After settling on a voltage value, additional information must be read from the MMC card. This data is stored in MMC card CSD register. The card sends CSD register content after receiving CMD9 command. The CSD register holds important information on the card, MMC system specification version support, maximum clock speed support, memory capacity, minimum block length, and read and write transfer latency timings.

24.6.1.3.4.1 Sending CMD9

This command asks the card to send its CSD register's content (see [Table 24-22](#)). The 136-bit (128 bits are valid payload) response is received in the MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54, and MMCHS1.MMCHS_RSP76 registers. CMD9 is an addressed command which means that the card's address must be written in the MMCHS1.MMCHS_ARG register before the command is issued.

Table 24-22. Sending CMD9

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x00070001	Enables CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00070001	Enables CCRC, CC, CTO and CEB interrupts to rise.

Table 24-22. Sending CMD9 (continued)

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CMD	0x4809C10C	0x09090000	Sends CMD9 whose opcode is 9, response type is 136 bits with CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

After receiving and parsing CMD9 response, MMC card clock speed must change to take advantage to card's maximum speed. This has an impact on MMC bus as we should perform a clock frequency change. At this stage the maximum clock frequency will be 20 MHz (see MMC system specification from www.mmca.org).

Clock frequency change procedure is performed in several steps. Please refer to [Section 24.5.2.7.2, MMCHS Clock Frequency Change](#).

[Table 24-23](#) shows the value written in MMCHS1.MMCHS_SYSCTL register.

Table 24-23. MMCHS_SYSCTL Value

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00000147	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 5 which means that MMCHS controller is supplying a 19.2 MHz clock < 20 MHz.

Another important parameter read from CSD register is MMC system specification version. If this parameter points to a value greater than or equal to 4, the MMC card is capable of a speed up to 52 MHz and a bus width up to 8 (1, 4 or 8 are the possible options). To enable these two extra features, MMCHS controller must issue a CMD6 command with specific argument.

A CMD6 command is issued in the data transfer mode after MMC card is selected. MMC card selection consists of sending CMD7 command with MMC card's address in command argument.

[Table 24-24](#) shows the set of register impacted by CMD7 issue action.

Table 24-24. Sending CMD7

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x071a0000	Sends CMD7 whose opcode is 7, response type is 48 bits with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

After a CMD7 transfer is complete, the MMC card is ready to receive a CMD6 command. CMD6 command is used to write a byte in MMC card extended CSD register (ext_csd). It is an IO access function. There are two write actions, the first one enables a specific data bus width in the card. For our use case we used data bus width 4. The second one enables high speed feature in the card.

24.6.1.3.4.1.1 Setting Data Bus Width to 4

[Table 24-25](#) shows the set of registers impacted by issuing CMD6.

Table 24-25. Setting Data Bus Width With CMD6

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x061b0000	Sends CMD6 whose opcode is 6, response type is 48 bits with busy, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x03b70100	(3 << 24) (byte_address << 16) (byte_value << 8). byte_address is the byte address in ext_csd register.

After issuing CMD6 completes successfully and MMC card leaves busy state, MMCHS controller should change its data bus width to 4. This is done by changing MMCHS1.MMCHS_HCTL configuration value.

Table 24-26. MMCHS_HCTL Value

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000002	MMCHS controller's data bus width is set to 4.

24.6.1.3.4.1.2 Enable High-Speed Feature

Table 24-27 shows the set of registers impacted by issuing CMD6 issuing.

Table 24-27. Enabling High-Speed With CMD6

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000002	MMCHS controller's data bus width is set to 4.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x061b0000	Sends CMD6 whose opcode is 6, response type is 48 bits with busy, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x03b90100	(3 << 24) (byte_address << 16) (byte_value << 8). byte_address is the byte address in ext_csd register.

After issuing CMD6 completes successfully and MMC card leaves busy state, MMCHS controller should now change its output clock to bring it to 48 MHz. 52 MHz, max frequency value supported by MMC card version 4 and above, is not supported because 96 MHz, MMCHS controller functional clock, is not a multiple of 52 MHz. We fall off to 48 MHz.

Table 24-28. MMCHS_SYSCTL Value

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00000087	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 2 which means that MMCHS controller is supplying a 48 MHz clock.

24.6.1.3.5 MMC Write Transfer

Either data read or data write transfer uses DMA controller to perform memory (DDRAM) to/from MMCHS controller transfers. The DMA part is not described in this chapter, it is described in [Chapter 11, SDMA](#).

Before any data transfer begins, the card must selected by issuing CMD7 command ([Table 24-24](#)).

A write transfer is a finite multiple block write transfer. To perform a write transfer, the following steps must be performed.

24.6.1.3.5.1 Send CMD16

Issuing CMD16 allows to set the block length. For our use case we decided to use a static block length of 512 bytes. The block length value is passed to the MMC card via MMCHS1.MMCHS_ARG register. The registers impacted by this operation are as follows:

Table 24-29. Setting Block Length

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000002	MMCHS controller's data bus width is set to 4.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x101a0000	Sends CMD16 whose opcode is 16, response type is 48 bits, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x000000200	Block length is 512 = 0x200

24.6.1.3.5.2 Send CMD23

Issuing CMD23 allows to set the number of how many 512-byte blocks the MMC card should expect from the MMCHS controller. The number of blocks is passed to MMC card via MMCHS1.MMCHS_ARG register. The registers impacted by this operation are as follows:

Table 24-30. Setting Number of Blocks

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000002	MMCHS controller's data bus width is set to 4.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x171a0000	Sends CMD23 whose opcode is 23, response type is 48 bits, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000008	Number of 512-byte blocks in 4 KB buffer is 8.

24.6.1.3.5.3 Send CMD25

Issuing CMD25 starts the finite, multiple block write transfer. Before the transfer starts, DMA controller should be configured for this operation. For more details about DMA configuration see [Chapter 11, SDMA](#).

Table 24-31. CMD25 Issuing

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000002	MMCHS controller's data bus width is set to 4.
MMCHS1.MMCHS_IE	0x4809C134	0x107f0013	Enables CERR, CIE, CCRC, CC, TC, BWR, CTO, DTO, DCRC, DEB and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x107f0013	Enables CERR, CIE, CCRC, CC, TC, BWR, CTO, DTO, DCRC, DEB and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x193a0023	Sends CMD25 whose opcode is 25, response type is 48 bits, with CICE, DP, MSBS, BCE, DE and CCCE enabled.

Table 24-31. CMD25 Issuing (continued)

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_ARG	0x4809C108	0x00000000	Not used
MMCHS1.MMCHS_BLK	0x4809C104	0x00080200	(number_blocks << 16) (block_length)

24.6.1.3.6 MMC Read Transfer

Either data read or data write transfer uses DMA controller to perform memory (DDRAM) to/from MMCHS controller transfers. The DMA part is not described in this document, it is described in [Chapter 11, SDMA](#).

Before any data transfer begins, the card must be selected by issuing CMD7 command ([Table 24-24](#)).

A read transfer is a finite multiple block write transfer. To perform a read transfer, the following steps must be performed.

24.6.1.3.6.1 Send CMD16

Issuing CMD16 allows to set the block length. For our use case we decided to use a static block length of 512 bytes. The block length value is passed to the MMC card via MMCHS1.MMCHS_ARG register. See [Table 24-29](#).

24.6.1.3.6.2 Send CMD23

Issuing CMD23 allows to set the number of how many 512-byte blocks the MMC card should expect from the MMCHS controller. The number of blocks is passed to MMC card via MMCHS1.MMCHS_ARG register. See [Table 24-30](#).

24.6.1.3.6.3 Send CMD18

Issuing CMD18 starts the finite, multiple block read transfer. Before the transfer starts, DMA controller should be configured for this operation. For more details about DMA configuration see [Chapter 11, SDMA](#).

Table 24-32. CMD18 Issuing

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000002	MMCHS controller's data bus width is set to 4.
MMCHS1.MMCHS_IE	0x4809C134	0x107f0023	Enables CERR, CIE, CCRC, CC, TC, BRR, CTO, DTO, DCRC, DEB and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x107f0023	Enables CERR, CIE, CCRC, CC, TC, BRR, CTO, DTO, DCRC, DEB and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x123a0033	Sends CMD18 whose opcode is 18, response type is 48 bits, with CICE, DP, MSBS, BCE, DE, DDIR and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000000	Not used
MMCHS1.MMCHS_BLK	0x4809C104	0x00080200	(number_blocks << 16) (block_length)

24.6.1.3.7 Dealing With High-Capacity Cards

Unlike standard-capacity cards, memory addressing mode for high-capacity cards (SDHC and HC MMC) is in 512-byte block format instead of byte format. This means that byte and partial accesses are not allowed with high-capacity cards.

The 32-bit wide argument configured in the [MMCHS_ARG](#) register and sent in data transfer commands CMD17, CMD18, CMD24, and CMD25, carries the block index where the read/write should start and not the 32-bit byte address.

For high-capacity cards, the block size is fixed at 512 bytes. Any data transfer, when the data bus is involved, must be a multiple of 512 bytes.

The number of blocks for a high-capacity card, which determines the capacity of the card block_count x 512 bytes, is accessible through field C_SIZE in the card's CSD register version 2.0 for SD cards, or through the SEC_COUNT field in the card's EXT_CSD register for MMC cards compliant with MMC specification version 4.x.

To write/read a packet whose size is less than 512 bytes to/from a high-capacity card, write/read the whole 512-byte block that contains the range of bytes to modify/read.

	0x480B 4024			
Description	Card status response error This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit MMCi.MMCHS_CSRE[I] is set to 1, if the corresponding bit at the same position in the response MMCi.MMCHS_RSP10[I] is set to 1, the host controller indicates a card error (MMCi.MMCHS_STAT[28] CERR bit) interrupt status to avoid the host driver reading the response register (MMCi.MMCHS_RSP10). Note: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (MMCi.MMCHS_RSP76) for possible card errors.

Table 24-41. MMCHS_SYSTEST

Address Offset	0x028	Instance	MMCHS1 MMCHS3 MMCHS2	
Physical Address	0x4809 C028			
	0x480A D028			
	0x480B 4028			
Description	System Test register This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification. Note: In SYSTEST mode, a write into MMCi.MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCi.MMCHS_BLK[10:0] BLEN bits) and the Blocks count for current transfer (MMCi.MMCHS_BLK[31:16] NBLK bits) are needed to generate a Buffer write ready interrupt (MMCi.MMCHS_STAT[4] BWR bit) or a Buffer read ready interrupt (MMCi.MMCHS_STAT[5] BRR bit) and DMA requests if enabled.

MMC/SD/SDIO Register Manual

www.ti.com

Bits	Field Name	Description	Type	Reset
31:17	Reserved	Reserved bit field. Do not write any value	R	0x00000
16	CLKEXTFREE	<p>External clock free running.</p> <p>This register is used to maintain card clock out of transfer transaction to enable slave module (for example to generate a synchronous interrupt on mmci_dat[1]). The Clock will be maintain only if MMCi.MMCHS_SYSCTL[2] CEN bit is set.</p> <p>0x0: External card clock is cut off outside active transaction period.</p> <p>0x1: External card clock is maintain even out of active transaction period only if MMCi.MMCHS_SYSCTL[2] CEN bit is set.</p>	RW	0
15	PADEN	<p>Control Power for MMC Lines.</p> <p>This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for mmci_dat[1], the signal is also combine outside the module with the dedicated power control MMCi.MMCHS_CON[11] CTPL bit.</p> <p>0x0: ADPIDE module pin is not forced, it is automatically generated by the MMC fsm.</p> <p>0x1: ADPIDE module pin is forced to active state.</p>	RW	0
14	OBIE	<p>Out-of-Band Interrupt Enable (MMC cards only).</p> <p>This bit enables the detection of Out-of-Band Interrupt on MMCOBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration.</p> <p>0x0: Out-of-Band interrupt detection disabled.</p> <p>0x1: Out-of-Band interrupt detection enabled.</p>	RW	0
13	OBIP	<p>Out-of-Band Interrupt Polarity (MMC cards only).</p> <p>This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration.</p> <p>0x0: active high level.</p> <p>0x1: active low level.</p>	RW	0
12	CEATA	<p>CE-ATA control mode (MMC cards compliant with CE-ATA):</p> <p>By default, this bit is set to 0. It is use to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features.</p> <p>0x0: Standard MMC/SD/SDIO mode.</p> <p>0x1: CE-ATA mode. Next commands are considered as CE-ATA commands.</p>	RW	0
11	CTPL	<p>Control Power for mmci_dat[1] line (MMC and SD cards):</p> <p>By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current.</p> <p>SDIO cards:</p> <p>When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of mmci_dat[1] outside of a transaction in order to detect asynchronous card interrupt on mmci_dat[1] line and minimize the leakage current of the buffers.</p> <p>0x0: Disable all the input buffers outside of a transaction.</p> <p>0x1: Disable all the input buffers except the buffer of mmci_dat[1] outside of a transaction.</p>	RW	0
10:9	DVAL	<p>Debounce filter value (All cards)</p> <p>This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: 33 us debounce period.</p> <p>0x1: 231 us debounce period.</p>	RW	0x3

Bits	Field Name	Description	Type	Reset
		0x2: 1 ms debounce period. 0x3: 8.4 ms debounce period.		
8	WPP	Write protect polarity (SD and SDIO cards only) This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level. 0x1: Active low level.	RW	0
7	CDP	Card detect polarity (All cards) This bit selects the active level of the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level. 0x1: Active low level.	RW	0
6	MIT	MMC interrupt command (Only for MMC cards.) This bit must be set to 1, when the next write access to the command register (MMCI. MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. 0x0: Command timeout enabled 0x1: Command timeout disabled	RW	0
5	DW8	8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification. 0x0: 1-bit or 4-bit Data width (mmci_dat[0] or mmci_dat[3:0] used, MMC, SD cards) 0x1: 8-bit Data width (mmci_dat[7:0] used, MMC cards)	RW	0
4	MODE	Mode select (All cards) These bits select the functional mode. 0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the MMCI. MMCHS_CMD register. 0x1: SYSTEST mode. The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.	RW	0
3	STR	Stream command (Only for MMC cards). This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP). 0x0: Block oriented data transfer. 0x1: Stream oriented data transfer.	RW	0

Bits	Field Name	Description	Type	Reset
2	HR	<p>Broadcast host response (Only for MMC cards). This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core. To have the host response to be generated in open drain mode, the register MMCHS_CON[OD] must be set to 1. When MMCI.MMCHS_CON[12] CEATA bit is set to 1 and MMCI.MMCHS_ARG set to 0x00000000, when writing 0x00000000 into MMCI.MMCHS_CMD register, the host controller performs a 'command completion signal disable' token (i.e. mmci_cmd line held to '0' during 47 cycles followed by a 1).</p> <p>0x0: The host does not generate a 48-bit response instead of a command.</p> <p>0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.</p>	RW	0
1	INIT	<p>Send initialization stream (All cards). When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the mmci_cmd line to 1 during 80 clock cycles. The initialization sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCI.MMCHS_SYSCTL[15:6] CLKD bits) should be set to ensure that 80 clock periods are greater than 1ms. Note: in this mode, there is no command sent to the card and no response is expected. A command complete interrupt will be generated once the initialization sequence is completed. MMCI.MMCHS_STAT[0] CC bit can be polled.</p> <p>0x0: The host does not send an initialization sequence.</p> <p>0x1: The host sends an initialization sequence.</p>	RW	0
0	OD	<p>Card open drain mode (Only for MMC cards). This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCI.MMCHS_CON[2] HR bit)</p> <p>0x0: No Open Drain</p> <p>0x1: Open Drain or Broadcast host response</p>	RW	0

Description	Power counter register This register is used to program a mmc counter to delay command transfers after activating the PAD power, this value depends on PAD characteristics and voltage.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															PWRcnt																

Bits	Field Name	Description	Type	Reset
31:16	Reserved	These bits are initialized to zero, and writes to them are ignored. Reads return 0.	R	0x00
15:0	PWRcnt	Power counter register. This register is used to introduce a delay between the PAD ACTIVE pin assertion and the command issued. 0x0: No additional delay added. 0x1: TCF delay (card clock period). 0x2: TCF x 2 delay (card clock period). 0xFFFFE: TCF x 65534 delay (card clock period). 0xFFFF: TCF x 65535 delay (card clock period).	RW	0x0000

Address Offset	0x104																														
Physical Address	0x4809 C104	Instance	MMCHS1																												
	0x480A D104		MMCHS3																												
	0x480B 4104		MMCHS2																												
Description	Transfer Length Configuration register This register shall be used for any card.																														
Type	RW																														
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NBLK												Reserved	BLEN																		

Bits	Field Name	Description	Type	Reset
31:16	NBLK	<p>Blocks count for current transfer. This register is enabled when Block count Enable (MMCI.MMCHS_CMD[1] BCE bit) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. Note: The host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count.</p> <ul style="list-style-type: none"> 0x0: Stop count 0x1: 1 block 0x2: 2 blocks 0xFFFF: 65535 blocks 	RW	0x0000
15:11	Reserved	Reserved bit field. Do not write any value	R	0x00
10:0	BLEN	<p>Transfer Block Size. This register specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLEN field after transfer completion (MMCI.MMCHS_STAT[1] TC bit set to 1) will not return the true byte number of data length while the stop occurs but the value written in this register before transfer is launched.</p> <ul style="list-style-type: none"> 0x0: No data transfer 0x1: 1 byte block length 0x2: 2 bytes block length 0x3: 3 bytes block length 0xFF: 511 bytes block length 0x200: 512 bytes block length 0x3FF: 1023 bytes block length 0x400: 1024 bytes block length 	RW	0x000

Table 24-51. MMCHS_CMD

Address Offset	0x10C		
Physical Address	0x4809 C10C	Instance	MMCHS1
	0x480A D10C		MMCHS3
	0x480B 410C		MMCHS2
Description	Command and transfer mode register MMCi.MMCHS_CMD[31:16] = the command register MMCi.MMCHS_CMD[15:0] = the transfer mode. This register configures the data and command transfers. A write into the most significant byte send the command. A write into MMCi.MMCHS_CMD[15:0] registers during data transfer has no effect. This register shall be used for any card.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	INDX		CMD_TYPE	DP	CICE	CCCE	Reserved	RSP_TYPE	Reserved										MSBS	DDIR	Reserved	ACEN	BCE	DE							

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Reserved bit field. Do not write any value	R	0x0
29:24	INDX	Command index Binary encoded value from 0 to 63 specifying the command number send to card 0x0: CMD0 or ACMD0	RW	0x00

Bits	Field Name	Description	Type	Reset
		0x1: CMD1 or ACMD1 0x3F: CMD63 or ACMD63		
23:22	CMD_TYPE	Command type. This register specifies three types of special command: Suspend, Resume and Abort. These bits shall be set to 0b00 for all other commands. 0x0: Others Commands 0x1: Upon CMD52 "Bus Suspend" operation 0x2: Upon CMD52 "Function Select" operation 0x3: Upon CMD12 or CMD52 "I/O Abort" command	RW	0x0
21	DP	Data present select. This register indicates that data is present and mmci_dat line shall be used. It must be set to 0 in the following conditions: - Command using only mmci_cmd line -Command with no data transfer but using busy signal on mmci_dat[0] -Resume command 0x0: Command with no data transfer 0x1: Command with data transfer	RW	0
20	CICE	Command Index check enable. This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCi.MMCHS_STAT[19] CIE bit set to 1) Note: The CICE bit cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0x0: Index check disable 0x1: Index check enable	RW	0
19	CCCE	Command CRC check enable. This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCi.MMCHS_STAT[17] CCRC bit set to 1). Note: The CCCE bit cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0x0: CRC7 check disable 0x1: CRC7 check enable	RW	0
18	Reserved	Reserved bit field. Do not write any value.	R	0
17:16	RSP_TYPE	Response type. This bits defines the response type of the command. 0x0: No response 0x1: Response Length 136 bits 0x2: Response Length 48 bits 0x3: Response Length 48 bits with busy after response	RW	0x0
15:6	Reserved	Reserved bit field. Do not write any value.	R	0x000
5	MSBS	Multi/Single block select. This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0. 0x0: Single block. If this bit is 0, it is not necessary to set the register MMCi.MMCHS_BLK[31:16] NBLK bits. 0x1: Multi block. When Block Count is disabled (MMCi.MMCHS_CMD[1] BCE bit is set to 0) in Multiple block transfers (MMCi.MMCHS_CMD[5] MSBS bit is set to 1), the module can perform infinite transfer.	RW	0
4	DDIR	Data transfer Direction. Select This bit defines either data transfer will be a read or a write. 0x0: Data Write (host to card) 0x1: Data Read (card to host)	RW	0

Bits	Field Name	Description	Type	Reset
3	Reserved	Reserved bit field. Do not write any value.	R	0
2	ACEN	Auto CMD12 Enable. (SDIO does not support this feature.) When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. For CE-ATA commands (MMCI. MMCHS_CON [12] CEATA bit set to 1), auto CMD12 is useless; therefore when this bit is set the mechanism to detect command completion signal, named CCS, interrupt is activated. 0x0: Auto CMD12 disable 0x1: Auto CMD12 enable or CCS detection enabled.	RW	0
1	BCE	Block Count Enable (Multiple block transfers only). This bit is used to enable the block count register (MMCHS_BLK [31:16] NBLK bits). When Block Count is disabled (MMCHS_CMD [1] BCE bit is set to 0) in Multiple block transfers (MMCHS_CMD [5] MSBS bits is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer. 0x1: Block count enabled for multiple block transfer with known number of blocks	RW	0
0	DE	DMA Enable. This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable	RW	0

Address Offset	0x120		
Physical Address	0x4809 C120	Instance	MMCHS1
	0x480A D120		MMCHS3
	0x480B 4120		MMCHS2
Description	Data Register This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput. Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer. Example 1: Byte or 16-bit access Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad

Reserved	CLEV	DLEV	Reserved	Reserved	Reserved	Reserved	Reserved	BRE	BWE	RTA	WTA	Reserved	Reserved	Reserved	Reserved	DLA	DATI	CMDI														

Bits	Field Name	Description	Type	Reset
31:25	Reserved	Reserved bit field. Do not write any value.	R	0x00
24	CLEV	mmci_cmd line signal level. This status is used to check the mmci_cmd line level to recover from errors, and for debugging. The value of this register after reset depends on the mmci_cmd line level at that time. Read 0x0: The mmci_cmd line level is 0. Read 0x1: The mmci_cmd line level is 1.	R	-
23:20	DLEV	mmci_dat[3:0] line signal level mmci_dat[3] => bit 23 mmci_dat[2] => bit 22 mmci_dat[1] => bit 21 mmci_dat[0] => bit 20 This status is used to check mmci_dat line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from mmci_dat[0]. The value of these registers after reset depends on the mmci_dat lines level at that time.	R	0x-
19	Reserved	Reserved bit field. Do not write any value	R	0
18	Reserved	Reserved bit field. Do not write any value This bit is not affected by soft reset.	R	1
17:16	Reserved	Reserved bit field. Do not write any value The value of these bits after soft reset is 0x0. These bits will be automatically set to 0x3 after debounce time. Debounce time is fixed to 256 x32 kHz clock cycles.	R	00
15:12	Reserved	Reserved bit field. Do not write any value	R	0x0
11	BRE	Buffer read enable. This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCI.MMCHS_BLK[10:0] BLEN bits has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCI.MMCHS_STAT[5] BRR bit). Read 0x0: Read BLEN bytes disable Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer.	R	0
10	BWE	Buffer Write enable. This status is used for non-DMA write transfers. It indicates if space is available for write data. Read 0x0: There is no room left in the buffer to write BLEN bytes of data. Read 0x1: There is enough space in the buffer to write BLEN bytes of data.	R	0

MMC/SD/SDIO Register Manual

www.ti.com

Bits	Field Name	Description	Type	Reset
9	RTA	<p>Read transfer active.</p> <p>This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCi.MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the mmci_dat lines.</p> <p>Read 0x1: Read data transfer on going.</p>	R	0
8	WTA	<p>Write transfer active.</p> <p>This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCi.MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the mmci_dat lines.</p> <p>Read 0x1: Write data transfer on going.</p>	R	0
7:3	Reserved	Reserved bit field. Do not write any value	R	0x00
2	DLA	<p>mmci_dat line active.</p> <p>This status bit indicates whether one of the mmci_dat line is in use. In the case of read transactions (card to host):</p> <p>This bit is set to 1 after the end bit of read command or by activating continue request MMCi.MMCHS_HCTL[17] CR bit. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card):</p> <p>This bit is set to 1 after the end bit of write command or by activating continue request MMCi.MMCHS_HCTL[17] CR bit.</p> <p>This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request.</p> <p>Read 0x0: mmci_dat Line inactive</p> <p>Read 0x1: mmci_dat Line active</p>	R	0
1	DATI	<p>Command inhibit (mmci_dat).</p> <p>This status bit is generated if either mmci_dat line is active (MMCi.MMCHS_PSTATE[2] DLA bit) or Read transfer is active (MMCi.MMCHS_PSTATE[9] RTA bit) or when a command with busy is issued. This bit prevents the local host to issue a command.</p> <p>A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCi.MMCHS_STAT[1] TC bit).</p> <p>Read 0x0: Issuing of command using the mmci_dat lines is allowed</p> <p>Read 0x1: Issuing of command using mmci_dat lines is not allowed</p>	R	0
0	CMDI	<p>Command inhibit(mmci_cmd).</p> <p>This status bit indicates that the mmci_cmd line is in use.</p> <p>This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted.</p> <p>This bit is set to 0 in either the following cases:</p> <ul style="list-style-type: none"> - After the end bit of the command response, excepted if there is a command conflict error (MMCi.MMCHS_STAT[17] CCRC bit or MMCi.MMCHS_STAT[18] CEB bit set to 1) or a Auto CMD12 is not executed (MMCi.MMCHS_AC12[0] ACNE bit). - After the end bit of the command without response (MMCi.MMCHS_CMD[17:16] RSP_TYPE bits set to "00"). In case of a command data error is detected (MMCi.MMCHS_STAT[19] CTO bit set to 1), this register is not automatically cleared. <p>Read 0x0: Issuing of command using mmci_cmd line is allowed</p> <p>Read 0x1: Issuing of command using mmci_cmd line is not allowed</p>	R	0

MMC/SD/SDIO Register Manual

www.ti.com

Bits	Field Name	Description	Type	Reset
19	IBG	<p>Interrupt block at gap.</p> <p>This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0.</p> <p>0x0: Disable interrupt detection at the block gap in 4-bit mode</p> <p>0x1: Enable interrupt detection at the block gap in 4-bit mode</p>	RW	0
18	RWC	<p>Read wait control.</p> <p>The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCi.MMCHS_HCTL[16] SBGR bit) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on mmci_dat line.</p> <p>0x0: Disable Read Wait Control. Suspend/Resume cannot be supported.</p> <p>0x1: Enable Read Wait Control</p>	RW	0
17	CR	<p>Continue request.</p> <p>This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCi.MMCHS_HCTL[16] SBGR bit). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e. mmci_dat line is active (MMCi.MMCHS_PSTATE[2] DLA bit) or transferring data (MMCi.MMCHS_PSTATE[8] WTA bit).</p> <p>The Stop at block gap request must be disabled (MMCi.MMCHS_HCTL[16] SBGR bit =0) before setting this bit.</p> <p>0x0: No affect</p> <p>0x1: transfer restart</p>	RW	0
16	SBGR	<p>Stop at block gap request.</p> <p>This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCi.MMCHS_HCTL[17] CR bit) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCi.MMCHS_STAT[1] TC bit set to 1), the host driver shall leave this bit set to 1. If this bit is set, the local host shall not write to the data register (MMCi.MMCHS_DATA).</p> <p>0x0: Transfer mode</p> <p>0x1: Stop at block gap</p>	RW	0
15:12	Reserved	Reserved bit field. Do not write any value.	R	0x0
11:9	SDVS	<p>SD bus voltage select (All cards).</p> <p>The host driver should set these bits to select the voltage level for the card according to the voltage supported by the system (MMCi.MMCHS_CAPA[26] VS18 bit, MMCi.MMCHS_CAPA[25] VS30 bit, MMCi.MMCHS_CAPA[24] VS33 bit) before starting a transfer.</p> <p>0x5: 1.8V (Typical)</p> <p>0x6: 3.0V (Typical)</p> <p>0x7: 3.3V (Typical)</p> <p>MMCHS2: This field must be set to 0x5.</p> <p>MMCHS3: This field must be set to 0x5.</p>	RW	0x0
8	SDBP	<p>SD bus power.</p> <p>Before setting this bit, the host driver shall select the SD bus voltage (MMCi.MMCHS_HCTL[11:9] SDVS bits). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCi.MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (MMCi.MMCHS_CAPA[VS*]).</p> <p>0x0: Power off</p> <p>0x1: Power on</p>	RW	0
7:2	Reserved	Reserved bit field. Do not write any value.	R	0x00

Bits	Field Name	Description	Type	Reset
1	DTW	<p>Data transfer width.</p> <p>For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with <i>MMC standard specification 4.x</i>.</p> <p>This register has no effect when the MMC 8-bit mode is selected (MMCI.MMCHS_CON[5] DW8 bit set to 1)</p> <p>For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card.</p> <p>0x0: 1-bit Data width (mmci_dat[0] used)</p> <p>0x1: 4-bit Data width (mmci_dat[3:0] used)</p>	RW	0
0	Reserved	Reserved bit field. Do not write any value.	R	0

16	CTO	<p>Command Timeout Error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles.</p> <p>Read 0x0: No error Write 0x0: Status bit unchanged Read 0x1: Time Out Write 0x1: Status is cleared</p>	RW	0
15	ERRI	<p>Error Interrupt. If any of the bits in the Error Interrupt Status register (MMCI.MMCHS_STAT[31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored.</p> <p>Read 0x0: No Interrupt Read 0x1: Error interrupt event(s) occurred</p>	R	0
14:10	Reserved	Reserved bit field. Do not write any value.	R	0x00
9	OBI	<p>Out-Of-Band interrupt (This interrupt is only useful for MMC card). This bit is set automatically when MMCI.MMCHS_CON[14] OBIE bit is set and an Out-of-Band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by MMCI.MMCHS_CON[13] OBIP bit. The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation.</p> <p>Read 0x0: No Out-Of-Band interrupt. Write 0x0: Status bit unchanged. Read 0x1: Interrupt Out-Of-Band occurs. Write 0x1: Status is cleared.</p>	R	0
8	CIRQ	<p>Card interrupt. This bit is only used for SD and SDIO cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives mmci_cmd line to zero during one cycle after data transmission end. All modes above are fully exclusive. The controller interrupt must be clear by setting MMCI.MMCHS_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCI.MMCHS_IE[8] CIRQ_ENABLE is set to 1. Writes to this bit are ignored.</p> <p>Read 0x0: No card interrupt Read 0x1: Generate card interrupt</p>	R	0
7:6	Reserved	Reserved bit field. Do not write any value.	RW	00

Bits	Field Name	Description	Type	Reset
5	BRR	<p>Buffer read ready.</p> <p>This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by the MMCI.MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it.</p> <p>Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated.</p> <p>Read 0x0: Not Ready to read buffer</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Ready to read buffer</p> <p>Write 0x1: Status is cleared</p>	RW	0
4	BWR	<p>Buffer write ready.</p> <p>This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCI.MMCHS_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer.</p> <p>Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated.</p> <p>Read 0x0: Not Ready to write buffer</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Ready to write buffer</p> <p>Write 0x1: Status is cleared</p>	RW	0
3	Reserved	Reserved bit field. Do not write any value	R	0
2	BGE	<p>Block gap event.</p> <p>When a stop at block gap is requested (MMCI.MMCHS_HCTL[16] SBGR bit), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.</p> <p>This event does not occur when the stop at block gap is requested on the last block.</p> <p>In read mode, a 1-to-0 transition of the mmci_dat line active status (MMCI.MMCHS_PSTATE[2] DLA bit) between data blocks generates a Block gap event interrupt.</p> <p>Read 0x0: No block gap event</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Transaction stopped at block gap</p> <p>Write 0x1: Status is cleared</p>	RW	0
1	TC	<p>Transfer completed.</p> <p>This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCI.MMCHS_HCTL[16] SBGR bit).</p> <p>This bit is also set when exiting a command in a busy state (if the command has a busy notification capability).</p> <p>In Read mode: This bit is automatically set on completion of a read transfer (MMCI.MMCHS_PSTATE[9] RTA bit).</p> <p>In write mode: This bit is set automatically on completion of the mmci_dat line use (MMCI.MMCHS_PSTATE[2] DLA bit).</p> <p>Read 0x0: No transfer complete</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Data transfer complete</p> <p>Write 0x1: Status is cleared</p>	RW	0
0	CC	<p>Command complete.</p> <p>This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCI.MMCHS_PSTATE[0] CMDI bit)</p> <p>If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCI.MMCHS_STAT[16] CTO bit) has higher priority than command complete (MMCI.MMCHS_STAT[0] CC bit).</p> <p>If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt.</p>	RW	0

Bits	Field Name	Description	Type	Reset
		Read 0x0: No Command complete		
		Write 0x0: Status bit unchanged		
		Read 0x1: Command complete		
		Write 0x1: Status is cleared

26	VS18	Voltage support 1.8V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCI_RESET signal). Read 0x0: 1.8 V Not Supported Write 0x0: 1.8 V Not supported Read 0x1: 1.8 V Supported Write 0x1: 1.8 V Supported MMCHS1, 2 and 3: This bit must be set to 1.	RW	0
25	VS30	Voltage support 3.0V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCI_RESET signal). Read 0x0: 3.0 V Not Supported Write 0x0: 3.0 V Not supported Read 0x1: 3.0 V Supported	RW	0

Bits	Field Name	Description	Type	Reset
		Write 0x1: 3.0 V Supported MMCHS1: This bit must be set to 1. MMCHS2 and 3: This bit must be left to 0.		
24	VS33	Voltage support 3.3V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCi_RESET signal) Read 0x0: 3.3 V Not Supported Write 0x0: 3.3 V Not supported Read 0x1: 3.3 V Supported Write 0x1: 3.3 V Supported MMCHS1, 2 and 3: This bit must be left to 0.	RW	0
23	SRS	Suspend/Resume support (SDIO cards only)This bit indicates whether the host controller supports Suspend/Resume functionality. Read 0x0: The Host controller does not Suspend/Resume functionality. Read 0x1: The Host controller supports Suspend/Resume functionality.	R	1
22	DS	DMA support. This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. Read 0x0: DMA Not Supported Read 0x1: DMA Supported	R	1
21	HSS	High speed support. This bit indicates that the host controller supports high speed operations and can supply an up-to-52 MHz clock to the card. Read 0x0: High Speed Not Supported Read 0x1: High Speed Supported	R	1
20:18	Reserved	Reserved bit field. Do not write any value.	R	0x0
17:16	MBL	Maximum block length. This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. The host controller supports 512 bytes and 1024 bytes block transfers. Read 0x0: 512 bytes Read 0x1: 1024 bytes Read 0x2: 2048 bytes	R	0x1
15:14	Reserved	Reserved bit field. Do not write any value	R	0x0
13:8	BCF	Base clock frequency for clock provided to the card. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method. See Chapter 3, Power, Reset, and Clock Management , for more information on the value of FUNC_96M_CLK clock signal.	R	0x00
7	TCU	Timeout clock unit. This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCi.MMCHS_STAT[20] DTO bit). Read 0x0: kHz Read 0x1: MHz	R	1
6	Reserved	Reserved. This bit is initialized to zero, and writes to it are ignored.	R	0
5:0	TCF	Timeout clock frequency. The timeout clock frequency is used to detect Data Timeout Error (MMCi.MMCHS_STAT[20] DTO bit). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register. Note: You can have the timeout clock frequency by dividing FUNC_96M_CLK by the value of the MMCi.MMCHS_SYSCTL[15:6] CLKD bit field.	R	0x00

General-Purpose Interface

This chapter describes the general-purpose interface for the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
25.1 General-Purpose Interface Overview	3494
25.2 General-Purpose Interface Environment	3497
25.3 General-Purpose Interface Integration	3500
25.4 General-Purpose Interface Functional Description	3507
25.5 General-Purpose Interface Basic Programming Model	3511
25.6 General-Purpose Interface Register Manual	3517

25.1 General-Purpose Interface Overview

The general-purpose interface combines six general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 192 (6 x 32) pins.

These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode when external events are detected. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode when external events are detected

These modules do not include pad control (pullup/down control, open-drain feature). For more information, see [Chapter 13, System Control Module](#).

25.1.1 Global Features

GPIOs include the following global features:

- Synchronous interrupt requests in active mode from each channel are processed by two identical interrupt generation submodules used independently by the imaging video and audio accelerator (IVA2.2) and the microprocessor unit (MPU) subsystems. One of these interrupts is mapped on the IVA2.2 subsystem interrupt controller (INTC) and the other on the MPU subsystem INTC.
- Asynchronous wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO module.
- Data input (capture)/output (drive)
- Power management support

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Each GPIO module produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

[Figure 25-1](#) shows an overview of the general-purpose interface.

Figure 25-1. General-Purpose Interface Overview

gpif-001

Each channel in GPIOs has the following features:

- The **GPIO_i.GPIO_OE** register controls the output capability for each pin.
- The output line level reflects the value written in the **GPIO_i.GPIO_DATAOUT** register through the level 4 (L4) interconnect.
- The input line can be fed to GPIO through an optional and configurable debounce cell. (The debouncing time value is global for all ports of one GPIO module, so up to five different debouncing time values are possible.)
- The input line value is sampled into the **GPIO_i.GPIO_DATAIN** register and can be read through the L4 interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level (logical 0, logical 1, or both) used can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: Rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the following registers:

- **GPIO_i.GPIO_DATAOUT**
- **GPIO_i.GPIO_IRQENABLE1**
- **GPIO_i.GPIO_IRQENABLE2**
- **GPIO_i.GPIO_WAKEUPENABLE**

For these registers, the modules implement the set-and-clear protocol register update (see [Section 25.5.2, Set and Clear Instructions](#)).

25.2 General-Purpose Interface Environment

The general-purpose interface combines six GPIO modules for a flexible, user-programmable, GPIO controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The general-purpose interface allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 25-2 shows a typical application using the general-purpose interface.

Figure 25-2. General-Purpose Interface Typical Application System Overview

NOTE: Temperature Sensing

Most memories provide a temperature sensor to control the auto-refresh duty cycle. The device monitors the temperature of the external memory using the `pop_tq_temp_sense_ft` ball and a GPIO input. To do this, `pop_tq_temp_sense_ft` is connected to a GPIO through the customer board. This feature is application-dependent.

CAUTION

Due to buffer strength, an external serial resistor must be connected to the balls corresponding to `gpio_120` to `gpio_129` pads.

GPIO multiplexed on these pads should only be used with special electrical attention, and if no other solutions are possible for their considered application.

They are not multiplexed on standard 1.8-V I/O cell buffers but specific dual -voltage USIM/MMC-compliant buffers with nonstandard voltage domains, power-up sequences, power states, and controls/configurations.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

25.2.1 GPIO as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. You can dedicate channels based on the keyboard matrix size ($r \times c$). Figure 25-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low-level.

Figure 25-3. General-Purpose Interface Used as a Keyboard Interface

gpiif-003

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low-level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see [Section 25.5.3, Interrupt and Wakeup](#)).

When the keyboard interrupt is received, the processor (the MPU and/or IVA2.2 subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

25.2.2 General-Purpose Interface Functional Interfaces

25.2.2.1 General-Purpose Interface Pins

Table 25-1 lists the interface pins of the general-purpose interface.

Table 25-1. I/O Pin Description

Signal Name	I/O ⁽¹⁾ ⁽²⁾	Description ⁽³⁾ ⁽²⁾	Reset Value
gpio_[31:0]	I/O	GPIO in configuration mode 4.	HiZ
gpio_[186:34]	I/O	GPIO in configuration mode 4.	HiZ
gpio_[191:188]	I/O	GPIO in configuration mode 4.	HiZ

⁽¹⁾ I = Input; O = Output

⁽²⁾ Some of the pins have special or restricted use. For more information, see [Table 25-5](#).

⁽³⁾ For more information about pin configuration modes, see [Chapter 13, System Control Module](#).

25.3 General-Purpose Interface Integration

25.3.1 Description

Figure 25-4 highlights the general-purpose interface integration in the device.

Figure 25-4. General-Purpose Interface Integration

gpif-004

25.3.1.1 Clocking, Reset, and Power-Management Scheme

25.3.1.1.1 Clocking

Each GPIO module uses two clocks:

- Debounce clock: The 32-KHz debounce clock, $\text{GPIO}_i\text{_DBCLK}$, (where $i = 1, 2, 3, 4, 5$, and 6 , with one debounce clock per module), comes from the PRCM module and is used for the debounce cell logic (without the corresponding configuration registers). This cell can sample the input line and filters the input level using a programmed delay.

For GPIO2 to GPIO6, this clock is controlled by the EN_GPIO_i (where $i = 2$ to 6) bit

$\text{PRCM.CM_FCLKEN_PER}$ (0: Disables, 1: Enables the clock). For GPIO1, this clock is controlled by the EN_GPIO1 bit $\text{PRCM.CM_FCLKEN_WKUP}[3]$ (0: Disables, 1: Enables the clock) for GPIO1.

- Interface clock: The interface clock, GPIO_i_ICLK (where $i = 1, 2, 3, 4, 5$, and 6), comes from the PRCM module and is used throughout GPIO (except within the debounce cell logic). The interface clock clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity. For GPIO1, this clock is controlled by the EN_GPIO1 bit PRCM.CM_ICLKEN_WKUP[3] (0: Disabled, 1: Enabled the clock) and the AUTO_GPIO1 bit PRCM.CM_AUTOIDLE_WKUP[3] (enables/disables automatic control of the interface clock). For GPIO2 to GPIO6, this clock is controlled by the EN_GPIO_i (where $i = 2$ to 6) bit PRCM.CM_ICLKEN_PER (0: Disables, 1: Enables the clock) and the AUTO_GPIO_i (where $i = 2$ to 6) bit PRCM.CM_AUTOIDLE_PER (enables/disables automatic control of the interface clock). [Table 25-2](#) describes the GPIO clocks.

Table 25-2. Clocks

Attribute	Frequency	Name	Mapping	Comments
Debounce clock	32 KHz	GPIO _i _DBCLK, where $i = 2$ to 6	PER_32K_ALWON_F	Source is PRCM module. CLK
		GPIO1_DBCLK	WKUP_32K_CLK	
Interface clock	Depends on PRCM registers settings	GPIO _i _ICLK, where $i = 2$ to 6	PER_L4_ICLK	
		GPIO1_ICLK	WKUP_L4_ICLK	

25.3.1.1.2 Reset

The general-purpose interface can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO module.

- Hardware reset: GPIO2 to GPIO6 are attached to the PER_RST reset domain. GPIO1 is attached to the WKUP_RST reset domain. The hardware reset has a global reset action on GPIOs of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low-level). In each GPIO module, the RESETDONE bit GPIO_i.[GPIO_SYSSTATUS](#)[0] monitors the internal reset status; it is set when the reset completes. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).
- Software reset: Each GPIO module has its own software reset using the GPIO_i.[GPIO_SYSCONFIG](#)[1] SOFTRESET bit (where $i = 1, 2, 3, 4, 5$, or 6). The software reset has the same effect as the hardware reset signal, but this reset can be applied on one or more modules. Writing 1 to the GPIO_i.[GPIO_SYSCONFIG](#)[1] SOFTRESET bit (where $i = 1, 2, 3, 4, 5$, or 6) resets the module. The bit value of 1 remains until the reset completes. When the software reset completes, the GPIO_i.[GPIO_SYSCONFIG](#)[1] SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset. The GPIO_i.[GPIO_SYSSTATUS](#)[0] RESETDONE bit is cleared during a software reset. This bit is set to 1 when the software reset completes.

25.3.1.1.3 Power Domain

GPIO1 is attached to the WKUP power domain (see [Chapter 3, Power, Reset, and Clock Management](#)). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUP power domain is continuously active. GPIO2 to GPIO6 are attached to the PER power domain (see [Chapter 3, Power, Reset, and Clock Management](#)). The PER power domain is not active continuously.

25.3.1.1.4 Power Management

25.3.1.1.4.1 Idle Scheme

To save dynamic consumption, an efficient idle scheme is based on:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring a complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIO_i_SWAKEUP, where $i = 1, 2, 3, 4, 5$, and 6) are sideband signals between the PRCM module and the general-purpose interface (see [Section 25.3.1.2, Hardware Requests](#)).

25.3.1.4.2 Operating Modes

The following four operating modes are defined for the modules:

- Active mode: The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- Idle mode: Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.
If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.
- Inactive mode: The module has no activity. The interface clock can be stopped, an interrupt cannot be generated, and the wake-up feature is inhibited.
- Disabled mode: The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

Idle and inactive modes are configured within the module and activated on request by the PRCM module (see [Chapter 3, Power, Reset, and Clock Management](#)) through sideband signals (see [Section 25.3.1.4.3, System Power Management and Wake-Up](#)).

The disabled mode is set by software through a dedicated configuration bit, the GPIO_i.[GPIO_CTRL\[0\]](#) DISABLEMODULE bit (0: The module is enabled and clocks are not gated; 1: The module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the L4 interconnect.

25.3.1.4.3 System Power Management and Wake-Up

The PRCM module can require GPIOs to be idled for power saving purposes.

The general-purpose interface has six identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see [Figure 25-4](#) and [Section 25.3.1.2, Hardware Requests](#)): One per GPIO module. The general-purpose interface allows GPIOs to enter idle mode based on the GPIO_i.[GPIO_SYSConfig\[4:3\]](#) IDLEMODE bit field.

The idle acknowledge depends on the configuration and activity of each GPIO module:

- Smart-idle mode (recommended)

When GPIO is configured in smart-idle mode (GPIO_i.[GPIO_SYSConfig\[4:3\]](#) IDLEMODE bit field [10]) and receives an idle request from the PRCM module (for GPIO2 to GPIO6: The corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for GPIO1: the PRCM.CM_FCLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, or the PRCM.CM_AUTOIDLE_WKUP[3] AUTO_GPIO1 bit set to 1 and L4 interface clock idle transitions), GPIO checks for more activity (capture of the input GPIO pins in the GPIO_i.[GPIO_DATAin](#) register is complete with no pending interrupt; all interrupt-status bits are cleared); and there is no access to the GPIO.[GPIO_DEBOUNCINGTIME](#) register pending synchronization.

The idle acknowledge is then asserted and the module enters into idle mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

When in idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs and the module is ready to issue a wake-up request.

When the expected transition occurs on an enabled GPIO input pin, GPIO exits from idle mode, if the

GPIOi.GPIO_SYSConfig[2] ENAWAKEUP bit is set to 1 (wake-up capability enabled), and the corresponding bit in the PRCM.PM_WKEN_PER register is also set to 1 for the GPIO2 to GPIO6, and/or the PRCM.PM_WKEN_WKUP[3] EN_GPIO1 bit is also set to 1 for GPIO1.

- Force-idle mode

When GPIO is configured in force-idle mode (GPIOi.GPIO_SYSConfig[4:3] IDLEMODE bit field [00]) and receives an idle request from the PRCM module for GPIO2 to GPIO6: The corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0, or the corresponding bit in PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for GPIO1: the PRCM.CM_FCLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, the PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, or the PRCM.CM_AUTOIDLE_WKUP[3] AUTO_GPIO1 bit set to 1 and the L4 interface clock idle transitions), GPIO waits unconditionally for an active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.

- No-idle mode

When GPIO is configured in no-idle mode (GPIOi.GPIO_SYSConfig[4:3] IDLEMODE bit field [01]) and receives an idle request from the PRCM module (for GPIO2 to GPIO6: The corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for GPIO1: the PRCM.CM_FCLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, or PRCM.CM_AUTOIDLE_WKUP[3] AUTO_GPIO1 bit set to 1 and L4 interface clock idle transitions), GPIO does not go to idle mode and the idle acknowledge is never sent.

NOTE: The GPIO2 to GPIO6 idle state can be checked by reading the corresponding status bits in the PRCM.CM_IDLEST_PER register (0: Active; 1: Idle) and is idle only when GPIO2 to GPIO6 are configured in smart-idle mode and have asserted their idle acknowledge.

The GPIO1 idle state can be checked by the PRCM.CM_IDLEST_WKUP[3] ST_GPIO1 bit (0: Idle, 1: active) and is idle only when GPIO1 is configured in smart-idle mode and has asserted its idle acknowledge.

GPIO2 to GPIO6 wake-up status can be checked by accessing the corresponding bits in the PRCM.PM_WKST_PER register (read 0: No wakeup occurred; read 1: Wakeup occurred; write 1: Status bit reset).

The GPIO1 wake-up status can also be checked by the PRCM.PM_WKST_WKUP[3] ST_GPIO1 bit (read 0: No wake-up occurred; read 1: Wakeup occurred; write 1: Status bit reset).

25.3.1.1.4.4 Module Power Saving

GPIO has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the L4 interconnect logic can be gated when the module is not accessed, if the GPIOi.GPIO_SYSConfig[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: The clock for the input data sample logic can be gated when the data in the register is not accessed.
- Clock gating for the event detection logic: Each GPIO module implements four clock groups used for the logic in synchronous events detection. Each group of eight input GPIO pins has a separate enable signal depending on the edge/level detection register setting. If a group requires no detection, the corresponding clock is gated off (see [Section 25.5.1, Power Saving by Grouping the Edge/Level Detection](#)). All channels are also gated using a one-out-of-N scheme. N is the GPIOi.GPIO_CTRL[2:1] GATINGRATIO bit field; it can take the values 1 (b00), 2 (0b01), 4 (b10), or 8 (0b11). The interface clock is enabled for this logic one cycle every N cycles. When N equals 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic runs at a frequency equal to

the interface clock frequency divided by N.

- Inactive mode: All internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. When set to 1, this bit forces clock gating for all internal clock paths. Module internal activity is suspended. The L4 interconnect is not affected by this bit.

Each 8-input group of GPIO has a clock-enable signal that can be enabled or disabled depending on the edge/level detection register setting. If a group requires no detection, then the corresponding clock is gated.

The interface clock gating is controlled with the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

25.3.1.2 Hardware Requests

25.3.1.2.1 Interrupt Requests

All interrupt sources (the 32 input GPIO channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Synchronous interrupt request lines 1 and 2 are active depending on their respective interrupt-enable 1 and 2 registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2).

- Synchronous interrupt request line 1 is mapped on the MPU INTC.
- Synchronous interrupt request line 2 is mapped on the IVA2.2 INTC.

Table 25-3 lists the interrupt lines that are driven out from the general-purpose interface to the MPU INTC and the IVA2.2 INTC.

Table 25-3. Interrupts

Name	Mapping	Comments
GPIO1		
GPIO1_MPU_IRQ	M_IRQ_29	Destination is the MPU INTC.
GPIO1_IVA2_IRQ	IVA2_IRQ[28]	Destination is the IVA2.2 INTC.
GPIO2		
GPIO2_MPU_IRQ	M_IRQ_30	Destination is the MPU INTC.
GPIO2_IVA2_IRQ	IVA2_IRQ[29]	Destination is the IVA2.2 INTC.
GPIO3		
GPIO3_MPU_IRQ	M_IRQ_31	Destination is the MPU INTC.
GPIO3_IVA2_IRQ	IVA2_IRQ[30]	Destination is the IVA2.2 INTC.
GPIO4		
GPIO4_MPU_IRQ	M_IRQ_32	Destination is the MPU INTC.
GPIO4_IVA2_IRQ	IVA2_IRQ[31]	Destination is the IVA2.2 INTC.
GPIO5		
GPIO5_MPU_IRQ	M_IRQ_33	Destination is the MPU INTC.
GPIO5_IVA2_IRQ	IVA2_IRQ[32]	Destination is the IVA2.2 INTC.
GPIO6		
GPIO6_MPU_IRQ	M_IRQ_34	Destination is the MPU INTC.
GPIO6_IVA2_IRQ	IVA2_IRQ[43]	Destination is the IVA2.2 INTC.

25.3.1.2.1.1 Wake-Up Generation

GPIO1 of the general-purpose interface is attached to the WKUP power domain (see [Chapter 3, Power, Reset, and Clock Management](#)) and can wake up the system.

NOTE: GPIO2 to GPIO6 modules belong to the PER power domain and thus have wake-up system capability only when the PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO module following the expected transition(s) (based on register programming). Each GPIO module generates a wake-up signal to the PRCM module.

NOTE: Only gpio_1, gpio_9, gpio_10, gpio_11, gpio_30, and gpio_31 can be used to generate a direct wake-up event. The other GPIO1 pins cannot be used to generate a direct wake-up event, because they are connected to the device I/O pad logic in the CORE power domain (VDD2). When the CORE power domain is OFF, the VDD2-supplied I/O pins of GPIO1 cannot generate a wake-up event.

The asynchronous wake-up request line is active based on the GPIO*i*.[GPIO_WAKEENABLE](#) register (where *i* = 1, 2, 3, 4, 5, and 6).

CAUTION

The wake-up capabilities of GPIO2 to GPIO6 are operational only when the PER power domain is active.

[Table 25-4](#) shows the wake-up signals mapping.

Table 25-4. Wake-Up Signals

Name	Mapping	Comments
GPIO <i>i</i> _WAKE	GPIO <i>i</i> _SWAKEUP	Where <i>i</i> = 1, 2, 3, 4, 5, and 6. Destination is the PRCM module.

[Table 25-5](#) describes the GPIO channels.

Table 25-5. GPIO Channel Description

Channel Number	Type ⁽¹⁾	Mapping	Wake-Up Feature	Comments
GPIO1				
[31:0]	I/O	gpio_[31:0]	Yes	GPIO ⁽²⁾
GPIO2

GPIO6				
[26:0]	I/O	gpio_[186:160]	Yes ⁽³⁾	GPIO ⁽²⁾
[27]	I	-	No	Not available on external balls. Read value is always 0.
[31:28]	I/O	gpio_[191:188]	Yes ⁽⁵⁾	GPIO ⁽⁶⁾

⁽⁴⁾ All configuration modes except configuration mode 4. See [Chapter 13, System Control Module](#).

⁽⁵⁾ Only when the PER power domain is active

⁽⁶⁾ Configuration mode 4. See [Chapter 13, System Control Module](#).

NOTE: The thermal shutdown comparator output signal (TSHUT) is an output from the BANDGAP module. This signal is low during normal operation and goes high during a thermal shutdown event. When channel 31 of GPIO4 is not connected to a ball of the device (the corresponding pin is configured in a mode different from the configuration mode 4; for more information about pin configuration see [Chapter 13, System Control Module](#)), TSHUT is connected to channel 31 of GPIO4, and an interrupt can be generated when a low-to-high transition occurs on TSHUT whether or not the interrupt generation for channel 31 of GPIO4 is correctly configured.

25.4 General-Purpose Interface Functional Description

[Figure 25-5](#) shows the general-purpose interface description.

Figure 25-5. General-Purpose Interface Description

[Figure 25-5](#) details GPIOs in the general-purpose interface block diagram with their configuration registers and their main functional paths:

- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO; the synchronous interrupt request lines 1 and 2 are active based on their respective interrupt-enable 1 and 2 registers (`GPIOi.GPIO_IRQENABLE1` and `GPIOi.GPIO_IRQENABLE2`). See [Figure 25-6](#).

Figure 25-6. Synchronous Path

- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO; the asynchronous wake-up request line is active based on the wakeup-enable register. See [Figure 25-7](#).

Figure 25-7. Asynchronous Path

- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode).

25.4.1 Operational Description

25.4.1.1 Interrupt and Wake-Up Features

25.4.1.1.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance). The 12 interrupt signals are GPIOi_MPU_IRQ (used by the MPU subsystem) and GPIOi_IVA2_IRQ (used by the IVA2.2 subsystem), where $i = 1, 2, 3, 4, 5$, and 6.

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the IVA2.2 subsystem and the MPU subsystem. Each submodule controls its own synchronous interrupt request line and has its own interrupt-enable (GPIOi.GPIO IRQENABLE1 or GPIOi.GPIO IRQENABLE2) and interrupt-status (GPIOi.GPIO IRQSTATUS1 or GPIOi.GPIO IRQSTATUS2) registers. The interrupt-enable register selects the channel(s) considered for the interrupt request generation, and the interrupt-status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt-status registers independent of the content of the interrupt-enable registers.

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see [Section 25.5.3, Interrupt and Wakeup](#)), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see [Section 25.3.1.1.4.4, Module Power Saving](#)). When an event matches the programmed settings (see [Section 25.5.3, Interrupt and Wakeup](#)), the corresponding bit in the interrupt-status register is set to 1 and, on the following interface clock cycle, the interrupt lines 1 and/or 2 are activated (depending on the interrupt-enable registers).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period equals N times the interface clock period; see [Section 25.3.1.1.4.4, Module Power Saving](#)). This minimum pulse width must be met before and after any expected level transition detection. For level detection, the selected level must be stable for at least two times the internally-gated interface clock period to trigger a synchronous interrupt.

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed four internally gated interface clock cycles plus one interface clock cycle when the debounce feature is not used.

When the debounce feature is active, the latency depends on the value of the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME) (see [Section 25.5.5, Debouncing Time](#)) and is less than three internally gated interface clock cycles plus two interface clock cycle, plus GPIOi.GPIO_DEBOUNCINGTIME register value debounce clock cycles plus three debounce clock cycles.

Synchronous interrupt request line 1 is mapped on the MPU INTC.

Synchronous interrupt request line 2 is mapped on the IVA2.2 INTC.

[Figure 25-8](#) shows an overview of the interrupt request generation.

Figure 25-8. Interrupt Request Generation

25.4.1.1.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has six wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per GPIO module. The wakeup-enable register (`GPIOi.GPIO_WAKEUPENABLE`) selects the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt-status registers (`GPIOi.GPIO_IRQSTATUS1` and `GPIOi.GPIO_IRQSTATUS2`).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see [Section 25.5.3, Interrupt and Wakeup](#)), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (`GPIOi_SWAKEUP`, where $i = 1, 2, 3, 4, 5$, and 6), if the wakeup-enable register is set.

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt-status registers (`GPIOi.GPIO_IRQSTATUS1` and `GPIOi.GPIO_IRQSTATUS2`). On the following internal clock cycle, the interrupt lines 1 and/or 2 are active (active low) when the corresponding bits are set in the interrupt-enable registers (`GPIOi.GPIO_IRQENABLE1` and `GPIOi.GPIO_IRQENABLE2`).

NOTE: When debouncing is not enabled, a minimum input pulse width does not trigger the wake-up request because there is no sampling operation.

When debouncing is enabled, the minimum pulse width is set by the specified debouncing time.

The `GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP` bit enables or disables the GPIO wake-up feature globally. If the bit is 0, the wakeup-enable register (`GPIOi.GPIO_WAKEUPENABLE`) has no effect.

Figure 25-9 shows an overview of the wake-up request generation.

Figure 25-9. Wake-Up Request Generation

25.4.1.1.3 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or IVA2.2 subsystem in the device) receives an interrupt request issued by GPIO, it reads the corresponding interrupt-status register (GPIO_i.[GPIO_IRQSTATUS1](#) or GPIO_i.[GPIO_IRQSTATUS2](#)) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the processor resets the status bit and releases the interrupt line by writing 1 in the corresponding bit of the interrupt-status register. If there is still a pending interrupt request to serve (all bits in the interrupt-status register that are not masked by the interrupt-enable register are not cleared), the interrupt line is reasserted.

NOTE: The status bit must be reset to re-enter idle mode.

25.5 General-Purpose Interface Basic Programming Model

25.5.1 Power Saving by Grouping the Edge/Level Detection

Each GPIO module implements four gated clocks used by the edge/level detection logic to save power. Each group of eight input GPIO pins generates a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no edge/level detection, then the corresponding clock is gated (cut off). Grouping the edge/level enable can save the power consumption of the module as described in the following example.

If any of the following registers

- `GPIOi.GPIO_LEVELDETECT0`
- `GPIOi.GPIO_LEVELDETECT1`
- `GPIOi.GPIO_RISINGDETECT`
- `GPIOi.GPIO_FALLINGDETECT`

are set to 0x01 01 01 01, all clocks are active (power consumption is high). If any of these registers are set to 0x00 00 00 FF, only one clock is active (power saving).

NOTE: When the clocks are enabled by writing to the `GPIOi.GPIO_LEVELDETECT0`, `GPIOi.GPIO_LEVELDETECT1`, `GPIOi.GPIO_RISINGDETECT`, and `GPIOi.GPIO_FALLINGDETECT` registers, the detection starts after five clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

The mechanism is independent of each clock group. If the clock was started before and a new setting is performed, the following is recommended: First, set the new detection required; second, disable the previous setting (if necessary). In this way, the corresponding clock is not gated and the detection starts immediately.

25.5.2 Set and Clear Instructions

25.5.2.1 Description

GPIO implements the set-and-clear protocol register update for the `GPIOi.GPIO_DATAOUT`, `GPIOi.GPIO_IRQENABLE1`, `GPIOi.GPIO_IRQENABLE2`, and `GPIOi.GPIO_WAKEUPENABLE` registers. This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear (recommended): Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing a 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

25.5.2.2 Clear Instruction

25.5.2.2.1 Clear Register Addresses

Clear interrupt-enable registers (`GPIOi.GPIO_CLEARIRQENABLE1` and `GPIOi.GPIO_CLEARIRQENABLE2`).

A write operation in the clear interrupt-enable1 (or enable2) register clears the corresponding bit in the interrupt-enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear interrupt-enable1 (or enable2) register returns the value of the interrupt-enable1 (or enable2) register.

Clear wakeup-enable register (`GPIOi.GPIO_CLEARWKUENA`).

A write operation in the clear wakeup-enable register clears the corresponding bit in the wakeup-enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear wakeup-enable register returns the value of the wakeup-enable register.

Clear data output register (GPIOi.GPIO_CLEARDATAOUT).

A write operation in the clear data output register clears the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear data output register returns the value of the data output register.

25.5.2.2.2 Clear Instruction Example

Assume the data output register (or one of the interrupt/wakeup-enable registers) contains the binary value 0b0000 0001 0000 0001 and you want to clear bit 0.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data output register (or at the address of the clear interrupt/wakeup-enable register). After this write operation, a reading of the data output register (or the interrupt/wakeup-enable register) returns 0b0000 0001 0000 0000; bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

Figure 25-10 shows an example of a clear instruction.

Figure 25-10. Write @GPIO_CLEARDATAOUT Register Example

25.5.2.3 Set Instruction

25.5.2.3.1 Set Register Addresses

Set interrupt-enable registers (GPIOi.GPIO_SETIRQENABLE1 and GPIOi.GPIO_SETIRQENABLE2).

A write operation in the set interrupt-enable1 (or enable2) register sets the corresponding bit in the interrupt-enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.

A read of the set interrupt-enable1 (or enable2) register returns the value of the interrupt-enable1 (or enable2) register.

Set wakeup-enable register (GPIOi.GPIO_SETWKUENA).

A write operation in the set wakeup-enable register sets the corresponding bit in the wakeup-enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the set wakeup-enable register returns the value of the wakeup-enable register.

Set data output register (GPIOi.GPIO_SETDATAOUT).

A write operation in the set data output register sets the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.

A read of the set data output register returns the value of the data output register.

25.5.2.3.2 Set Instruction Example

Assume the interrupt-enable1 (or enable2) register (or the data output register) contains the binary value, 0b0000 0001 0000 0000, and you want to set bits 15, 3, 2, and 1.

With the set instruction feature, write 0b1000 0000 0000 1110 at the address of the set interrupt-enable1 (or enable2) register (or at the address of the set data output register). After this write operation, a reading of the interrupt-enable1 (or enable2) register (or the data output register) returns 0b1000 0001 0000 1110; bits 15, 3, 2, and 1 are set.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

Figure 25-11 shows an example of a set instruction.

Figure 25-11. Write @GPIO_SETIRQENABLEEx Register Example

The set wakeup-enable register offers the same feature with the wakeup-enable register.

25.5.3 Interrupt and Wakeup

25.5.3.1 Involved Configuration Registers

- Interrupt-enable registers (GPIOi.GPIO IRQENABLE1 and GPIOi.GPIO IRQENABLE2)

The interrupt-enable1 (or interrupt-enable2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line1 (or line2). The interrupt-enable registers are programmed synchronously with the interface clock.

These registers can be accessed with direct read/write operations or using the alternate set-and-clear protocol register update feature. This feature enables to set or clear specific bits of these registers with a single write access to the corresponding set interrupt-enable1 (or interrupt-enable2) registers (or to the clear interrupt-enable1 [or interrupt-enable2] registers) address (see [Section 25.5.2, Set and Clear Instructions](#)).

- Wakeup-enable register (GPIOi.GPIO WAKEUPENABLE)

The wakeup-enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wakeup-enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.

This register can be accessed with direct read/write operations or by using the alternate set-and-clear protocol register update feature. This feature allows setting or clearing specific bits of this register with a single write access to the set wakeup-enable register (or to the clear wakeup-enable register) address (see [Section 25.5.2, Set and Clear Instructions](#)).

NOTE: There must be a correlation between wakeup-enable and interrupt-enable registers. If a GPIO pin has a wakeup configured on it, it should also have the corresponding interrupt enabled (on one of the two interrupt lines). Otherwise, it is possible to have a wake-up event, but after exiting the Idle mode, no interrupt is generated, thus the corresponding bit from the interrupt-status register is not cleared, and the module does not acknowledge a future IDLE request.

- Interrupt status registers (GPIOi.GPIO_IRQSTATUS1 and GPIOi.GPIO_IRQSTATUS2)

The interrupt-status1 (or interrupt-status2) register determines which of the input GPIO pins triggered the interrupt line1 (or interrupt line2) request (or the wake-up line).

When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wakeup). To reset a bit in this register, write 1 to the appropriate bit. However, an interrupt cannot be generated by writing 1 to the interrupt-status1 (or interrupt-status2) register.

If 0 is written to a bit in this register, the value remains unchanged. The interrupt-status1 (or interrupt-status2) register is synchronous with the interface clock. In idle mode, the event is detected through an asynchronous path, and the corresponding bit in the interrupt-status1 and interrupt-status2 registers are set when GPIO is awake.

NOTE: The wake-up capabilities of GPIO2 to GPIO6 are operational only when the PER power domain is active.

25.5.3.2 Description

To generate interrupt request to a host processor (the MPU and/or digital signal processor [DSP] subsystem in the device) at a defined event (level or edge logic transition) occurring on a GPIO pin (interrupt source), the GPIO configuration registers must be programmed as follows:

1. The GPIO channel must be configured as input by the output-enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register).
2. The expected event(s) on the GPIO input to trigger the interrupt request must be selected in the low-level interrupt-enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_LEVELDETECT0), and/or high-level interrupt-enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_LEVELDETECT1), and/or rising-edge interrupt/wakeup-enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_RISINGDETECT), and/or falling edge interrupt/wakeup-enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_FALLINGDETECT).

NOTE: Interrupt generation on both edges on one input is configured by setting the corresponding bit to 1 in the rising detect enabling register (GPIOi.GPIO_RISINGDETECT) and falling detect enabling register (GPIOi.GPIO_FALLINGDETECT) along with the interrupt-enable by setting the corresponding bit to 1 in one or both interrupt-enable registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2).

Simultaneous enabling of high-level and low-level detections for one given pin creates a constant-interrupt generator.

3. Interrupts from the GPIO channel must be enabled in the interrupt 1 enable register (write 1 to the corresponding bit of the GPIOi.GPIO_IRQENABLE1 register) and/or the interrupt 2 enable register (write 1 to the corresponding bit of the GPIOi.GPIO_IRQENABLE2 register).

To configure a GPIO module to send a wake-up request to the PRCM module at a defined event (logic transition) occurring on a GPIO pin (wake-up source), the GPIO configuration registers must be programmed as follows:

1. The GPIO pin must be configured as input by the output-enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register).
2. The expected event(s) on the GPIO input to trigger the wake-up request must be selected in the rising-edge interrupt/wakeup-enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_RISINGDETECT) and/or falling-edge interrupt/wakeup-enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_FALLINGDETECT). The wake-up request can be generated only on edge transitions.
3. The GPIO channel must be enabled in the wakeup-enable register (write 1 to the corresponding bit of the GPIOi.GPIO_WAKEUPENABLE register).
4. The wake-up request generation on the expected transition occurring on the GPIO input pins must enable the module (write 1 to the corresponding bit of the GPIOi.GPIO_SYSConfig[2] ENAWAKEUP).

bit).

CAUTION

For each GPIO channel used, do not forget to configure the corresponding pad configuration registers in the system control module (SCM).

After servicing the interrupt, the status bit in the interrupt-status register (`GPIOi.GPIO_IRQSTATUS1` or `GPIOi.GPIO_IRQSTATUS2`) must be reset and the interrupt line released (by writing 1 in the corresponding bit of the interrupt-status register) before enabling an interrupt for the GPIO channel in the interrupt-enable register (`GPIOi.GPIO_IRQENABLE1` or `GPIOi.GPIO_IRQENABLE2`) to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

25.5.4 Data Input (Capture)/Output (Drive)

The output-enable register (`GPIOi.GPIO_OE`) controls the output/input capability for each pin. At reset, all the GPIO-related pins are configured as input and output capabilities are disabled. This register is not used within the module. Its only function is to carry the pads configuration.

When configured as an output (the desired bit reset in the `GPIOi.GPIO_OE` register), the value of the corresponding bit in the `GPIOi.GPIO_DATAOUT` register is driven on the corresponding GPIO pin. Data is written to the data output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set-and-clear protocol register update feature. This feature lets you set or clear specific bits of this register with a single write access to the set output data register (`GPIOi.GPIO_SETDATAOUT`) or to the clear output data register (`GPIOi.GPIO_CLEARDATAOUT`) address (see [Section 25.5.2, Set and Clear Instructions](#)). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wakeup-enable (`GPIOi.GPIO_WAKEUPENABLE`) and the interrupt-enable (`GPIOi.GPIO_IRQENABLE1` and `GPIOi.GPIO_IRQENABLE2`) registers.

When configured as an input (the desired bit set to 1 in the `GPIOi.GPIO_OE` register), the state of the input can be read from the corresponding bit in the `GPIOi.GPIO_DATAIN` register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock (see [Section 25.5.2, Set and Clear Instructions](#)). When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the cycles required to synchronize and write data). If the application uses a pin as an input, the application must properly configure the wakeup-enable (`GPIOi.GPIO_WAKEUPENABLE`) and the interrupt-enable (`GPIOi.GPIO_IRQENABLE1` and `GPIOi.GPIO_IRQENABLE2`) registers to the interrupt and wake-up feature as needed.

25.5.5 Debouncing Time

To enable the debounce feature for a pin, the GPIO configuration registers must be programmed as follows:

1. The GPIO pin must be configured as input in the output-enable register (write 1 to the corresponding bit of the `GPIOi.GPIO_OE` register).
2. The debouncing time must be set in the debouncing time register (`GPIOi.GPIO_DEBOUNCINGTIME`).

The debouncing value register (`GPIOi.GPIO_DEBOUNCINGTIME`) is used to set the debouncing time for all input lines in GPIO. The value is global for all the ports of one GPIO module, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of the clock cycle(s) (one cycle is 31 μ s long) to be used.

The following formula describes the required input stable time to be propagated to the debounced output:

Required input line stable = (`GPIOi.GPIO_DEBOUNCINGTIME[7:0]` DEBOUNCV_{AL} bit field value + 1) x 0.031 ms.

where `GPIOi.GPIO_DEBOUNCINGTIME[7:0]` bit field DEBOUNCV_{AL} value is from 0 to 255.

3. The debouncing feature must be enabled in the debouncing-enable register (write 1 to the corresponding bit of the `GPIOi.GPIO_DEBOUNCENABLE` register).

25.6 General-Purpose Interface Register Manual

This section summarizes the hardware interface for the GPIO product. Each module instance within the design is shown, together with the module register map and bit definitions for each bit field.

[Table 25-6](#) lists the base address and address space for GPIO instances.

Table 25-6. Instance Summary

Module Name	Base Address	Size
GPIO1	0x4831 0000	4KB
GPIO2	0x4905 0000	4KB
GPIO3	0x4905 2000	4KB
GPIO4	0x4905 4000	4KB
GPIO5	0x4905 6000	4KB
GPIO6	0x4905 8000	4KB

25.6.1 General-Purpose Interface Register Mapping Summary

All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little endian encoding). Access to registers is direct; no shadow registers are implemented.

[Table 25-7](#) through [Table 25-12](#) describe the GPIO register offset addresses.

Table 25-7. GPIO1 Register Summary

GPIO_SETDATAOUT	RW	32	0x094	0x4905 8094

The write latency for all the R/W registers is immediate (with respect to the interface clock).

NOTE: When two write accesses in the GPIOi.GPIO_DEBOUNCINGTIME register are performed in less than two debounce clock cycles (32 kHz) plus four interface clock cycles, the first write access latency is immediate, but the second write access is acknowledged only after this interval ends.

In the register descriptions in this section, when one single register carries an individual configuration or setting for all the channels of the module, 1 bit in the register is dedicated to each channel. The bit and the corresponding channel are identified with the same number: Bit 0 refers to channel 0, bit 1 refers to channel 1, and so on, up to 31.

25.6.2 Register Descriptions

Table 25-13 through Table 25-63 describe the register bits.

Table 25-13. GPIO_REVISON

Address Offset	0x000	Physical Address	0x4831 0000	Instance	GPIO1
			0x4905 0000		GPIO2
			0x4905 2000		GPIO3
			0x4905 4000		GPIO4
			0x4905 6000		GPIO5
			0x4905 8000		GPIO6
Description	This register contains the IP revision code.				
Type	R				

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																									GPIOREVISION						

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0	R	0x000000
7:0	GPIOREVISION	IP revision [7:4] Major revision [3:0] Minor revision Examples: 0x10 for 1.0, 0x21 for 2.1	R	See ⁽¹⁾

⁽¹⁾ TI internal data

Table 25-15. GPIO_SYS CONFIG

Address Offset	0x010	Physical Address	0x4831 0010	Instance	GPIO1
			0x4905 0010		GPIO2
			0x4905 2010		GPIO3
			0x4905 4010		GPIO4
			0x4905 6010		GPIO5
			0x4905 8010		GPIO6
Description	This register controls the various parameters of the L4 interconnect.				
Type	RW				

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0s for future compatibility. Read returns 0	RW	0x0000000
4:3	IDLEMODE	Power Management, Req/Ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module 0x3: Reserved do not use	RW	0x0
2	ENAWAKEUP	Wake-up capability enabled/disabled 0x0: Wakeup disable 0x1: Wakeup enable	RW	0x0
1	SOFTRESET	Software reset. This bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset	RW	0x0
0	AUTOIDLE	Internal interface clock gating strategy 0x0: Interface clock is free-running 0x1: Automatic interface clock gating strategy is applied, based on the L4 interconnect activity	RW	0x0

Initialization

This chapter introduces the initialization steps in the general-purpose (GP) device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
26.1 Initialization Overview	3542
26.2 Preinitialization	3543
26.3 Power, Clocks, and Reset Power-Up Sequence	3552
26.4 Device Initialization by ROM Code	3552
26.5 Wake-Up Booting by ROM Code	3608
26.6 Debug Configuration	3612

26.1 Initialization Overview

This chapter provides an overview of the requirements for initializing the device from power on to firmware execution. An overview of the overall initialization process is given, including hardware- and software-related steps, a general overview of the boot ROM code operational requirements, and behavioral expectations.

26.1.1 Terminology

- Bootstrap: Initial software (SW) launched by the ROM code during the memory booting phase
- Downloaded software: Initial software downloaded into the internal static RAM (SRAM) by the ROM code during the peripheral booting phase
- eFuse: A one-time programmable memory location usually set at the factory
- Flash loader: Downloaded software launched by the ROM code in preflashing. It also programs an image in external memories.
- GP device: General-purpose device
- Initial software: Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software.
- Memory booting: ROM code mechanism that consists of executing initial software from external memory
- Peripheral booting: ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM.
- Permanent booting device: Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device. The permanent booting device is used after warm reset if no software booting configuration is programmed.
- Preflashing: A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- ROM code: The on-chip software in ROM that implements booting

26.1.2 Initialization Process

[Figure 26-1](#) is an overview of the initialization process and its steps:

- Preinitialization
- Power/clock/reset ramp sequence
- Boot ROM
- Boot loader
- OS/application

Each step, up to OS/applications running, is explained in the following sections.

Figure 26-1. Initialization Process

The first two steps in the initialization process are hardware-oriented; however, they require understanding of the process of configuring those system interface pins (balls on the device) that have software-configurable functionality. This configuration is an essential part of chip configuration and is application-dependent. This chapter refers to those pins and the associated configuration registers that are vital for correct device initialization.

26.2 Preinitialization

To accomplish a successful boot-up operation with a general-purpose (GP) device, certain hardware configuration settings must be in place. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the microprocessor unit (MPU), must be connected and driven correctly for successful device initialization. The following sections describe the specific requirements for the preinitialization stage.

26.2.1 Power Connections

The device can be supplied by an external power integrated circuit (IC).

Figure 26-2 shows example power connections between the device and the power IC.

Figure 26-2. Device and Power Connections

init_GN3-001

NOTE: Figure 26-2 is an example of power connections between the device and the power IC. These connections depend on the application: For example, if a serial display or camera interface is used, it must be supplied by a low-dropout (LDO) regulator (low noise).

NOTE:

- The sys_clkout output clock cannot be provided to peripherals when the core is off.
- The sys_clkreq output signal switches the system clock on or off.
- After power-on reset (POR), the hardware configuration enables the internal oscillator (assuming that the input clock comes from a crystal). The decision whether to bypass the internal oscillator is controlled by the polarity of the sys_boot[6] pin.

Table 26-1 describes the power pins.

Table 26-1. Power Pins⁽¹⁾

Device Voltage Pin Name	Description
vdd_mpu_iva	MPU and image and video accelerator (IVA) subsystem power supply
vdd_core	Core power supply
vdds_io	I/O power supply
vdds_mem	Memory, SDRC, and GPMC I/O power supply
vdda_wkup_bg_bb	Input power for wakeup, band gap and body bias low-dropout regulators (LDO)
vdda_sram	Input power for SRAM LDOs (common)
vdda_dplls_dll	Input power for digital phase-locked loops (DPLL) and delay-locked loop (DLL)
vdda_dpll_per	Input power for DPLL (peripheral)
vdda_csiphy1	Dedicated power supply for camera serial interface2 - CSI2a complex I/O
vdds_csiphy2	Dedicated power supply for CSI2b complex I/O
vdda_dsi	Dedicated power supply for display serial interface (DSI) complex I/O
vdda_dac	Video buffers and digital-to-analog converter (DAC) power supply
vdds_sdmmc1	Power supply for multimedia card (MMC)/secure digital (SD) dual voltage buffers
vpp	eFuse programming voltage
pop_ddr_vdd_ft	POP DDR core supply ⁽¹⁾
pop_flash_vdd_ft	POP FLASH core supply ⁽¹⁾
pop_flash_vpp_ft	POP FLASH vpp supply ⁽¹⁾

⁽¹⁾ The package-on-package (POP) device provides feedthroughs from the bottom of the package to the POP interface. Among these feedthroughs (FEEDTHROUGH balls), several provide power to the top memory device. The correct power supply to the feedthroughs must be provided based on memory requirements.

For more information about power management, see [Chapter 3, Power, Reset, and Clock Management](#).

26.2.2 Clock and Reset

26.2.2.1 Clock and Reset Overview

Figure 26-3 shows the clock and reset environment that gathers the clocks and reset signals related at the system level, as well as system expansion signals.

Figure 26-3. Clock and Reset Environment

init-004

The main features of the system interface are:

- A clock request output to an external square clock source
- 12, 13, 16.8, 19.2, 26, or 38.4-MHz reference clock input from the external crystal oscillator (only 12, 13, 16.8, or 19.2 MHz) or the digital clock input (all frequencies)
- 32-kHz CMOS clock input
- An additional clock input up to 54 MHz
- Two configurable output clocks
- Seven input signals to define the boot mode
- Two reset sources
 - POR (cold reset)
 - Bidirectional warm reset

26.2.2.2 Clock Configuration

26.2.2.2.1 Required System Input Clocks

Figure 26-4 shows the clock interface.

Figure 26-4. Clock Interface

Solution 1: Use of internal oscillator:

Solution2: Use of an external square clock source:

NOTE:

- The sys_clkout output clock cannot be provided to peripherals when the core is off.
- The sys_clkreq output signal switches the system clock on or off.
- After POR, the hardware configuration enables the internal oscillator (assuming that the input clock comes from a crystal). The decision whether to bypass the internal oscillator is controlled by the polarity of the sys_boot[6] pin.

The device operation requires two external input clocks, as follows:

- sys_32k: The 32-kHz frequency is used for low-frequency operation.
- sys_xtal (in/out): The system clock is the main clock source of the device. The system clock input can be connected in either of two ways:
 - Crystal quartz through the sys_xtalin and sys_xtalout pins, using an internal oscillator up to 19.2 MHz
 - Complementary metal oxide semiconductor (CMOS) digital clock (square clock) through the sys_xtalin pin. The oscillator is bypassed.

Table 26-2 lists the mapping for input sources.

Table 26-2. Mapping For Input Sources

Input Source	Mapping	Frequencies	Comment
Crystal quartz	sys_xtalin and sys_xtalout	12, 13, 16.8, or 19.2 MHz	Requires use of internal oscillator
Square clock (1.8 CMOS signal)	sys_xtalin (sys_xtalout unconnected)	12, 13, 16.8, 19.2, 26, or 38.4 MHz	Internal oscillator is bypassed.

Because sys_32k, sys_xtalin, and sys_xtalout have permanently assigned pin locations with no pad configuration for these pins through a system control module (SCM) register, only one source input at a time can be used.

26.2.2.2.2 Optional System Input Clock: sys_altclk

An additional clock can be provided through the sys_altclk input pin to supply internal peripherals, PLLs, a precise clock for National Television System Committee (NTSC) standard (54 MHz), and a universal serial bus (USB) full-speed (FS) controller (48 MHz). If not used as a clock input, this pin can be configured as a general-purpose input/output (GPIO), using the SCM CONTROL.CONTROL_PADCONF_I2C3_SDA register. As an example, to use the sys_altclk pin, the CONTROL.CONTROL_PADCONF_I2C3_SDA[18:16] MUXMODE1 bit field must be set to 0x01.

26.2.2.2.3 Optional System Output Clock: sys_clkout1 and sys_clkout2

Two output clocks (sys_clkout1 and sys_clkout2 pins) are available:

- sys_clkout1 can output the oscillator clock. Its OFF state polarity is programmable.
- sys_clkout2 can output the system clock (12, 13, 16.8, 19.2, 26, or 38.4 MHz), the core clock (CORE DPLL output), 96 MHz, or 54 MHz. sys_clkout2 can be divided by 2, 4, 8, or 16, and its OFF state polarity is programmable.

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies may not be applicable to production.

The clocks can be managed by software with the appropriate register in the power, reset, clock, management (PRCM) module:

- sys_clkout1 is managed using PRCM.PRM_CLKOUT_CTRL and PRCM.PRM_POLCTRL[2].
- sys_clkout2 is managed using PRCM.CM_CLKOUT_CTRL and PRCM.CM_CLKSEL1_PLL[28:27].

26.2.2.3 Reset Configuration

The sys_nrespwron reset pin resets the entire chip during POR.

The sys_nreswarm reset pin resets the entire chip when the device is supplied and operating, except for the following:

- Part of synchronous dynamic RAM (SDRAM) controller (SDRC)
- Part of IVA
- Part of PRCM
- Control module
- Watchdog
- 32-kHz synchronization timer
- DPLLS
- SmartReflex™ modules

CAUTION

sys_nrespwron must be driven low during a power-up sequence.

sys_nreswarm is a bidirectional reset. When an internal reset occurs, sys_nreswarm goes low and resets all the peripherals. The sys_nreswarm output is open-drain; consequently, an external pullup resistor is required.

sys_nrespwron and sys_nreswarm have permanently assigned pin locations.

At reset, the cause of reset is stored in the PRCM.RM_RSTST_MPUR register and used by the boot ROM code.

26.2.3 Boot Configuration

Six external pins (sys_boot[5:0]) are used to select interfaces or devices for booting. The sys_boot[6] pin is used to select whether the internal oscillator is bypassed.

These seven pins are sampled and latched onto the CONTROL.CONTROL_STATUS register after POR. After booting, these pins can be used for other functions and the associated CONTROL.CONTROL_STATUS bits are not updated by the new functionality. For more information about pad multiplexing configuration, see [Chapter 13, System Control Module](#).

NOTE: If used as GPIOs, these pins must be used in output mode. To ensure that the sys_boot[6:0] input values are selected by the pullup/down on sys_boot[6:0] pins at POR, these GPIOs must be used only in output mode. Because these balls have no pullup/down capacity, care must be taken when choosing to use these GPIOs.

[Table 26-3](#), [Table 26-4](#), and [Table 26-5](#) are decoding tables for sys_boot pins. Depending on sys_boot pin configuration during the reset (leftmost column), the ROM code tries to boot on the first booting device listed. If the boot fails on this first booting device, the ROM code tries the second booting device, then the third, then the fourth.

The following names are used in the tables:

- Memory types:
 - Execute in place (XIP): XIP memory without wait monitoring enabled (NOR flash memories)
 - XIP wait: XIP memory with wait monitoring
 - DOC: DiskOnChip™ memory (H3 device types)
 - NAND: NAND flash memories (non-XIP)
 - OneNAND: OneNAND™ and Flex-OneNAND™ flash memories
 - MMC1: MMC or SD/ eMMC or eSD flash cards connected to the first MMC/Secure Digital Input/Output (SDIO1) card interface
 - MMC2: MMC or SD/ eMMC or eSD flash cards to the second (MMC/SD/SDIO2) card interface
 - MMC2_H (Hybrid): MMC or SD/ eMMC or eSD flash cards connected to the second (MMC/SD/SDIO2) card interface, but the memory core is powered by VMMC1_LDO of the power-management IC.
- Peripheral interfaces:
 - USB: High-speed (HS) USB
 - UART3: UART interface
- Permanent booting devices are in *italics*.

[Table 26-3](#) and [Table 26-4](#) list the sys_boot pin configuration after a POR.

NOTE: After reset release, the ROM code tries to boot from several interfaces, one after the other until it finds a bootable one. These interfaces (GPMC, MMC1, MMC2, USB, and UART) are selected in a specific order defined by the sys_boot settings.

As a consequence, if the first bootable interface found by the ROM code is not the first one in the list, some activity occurs on the interfaces tested before the bootable one.

This must be considered in case these intermediary interfaces are connected to other peripherals for other purposes (for example, an LED connected to a GPMC pad muxed internally to a GPIO).

CAUTION

- UART boot: UART3 is the only possible UART from which boot can be performed. Additionally, only UART3 pins that provide UART3 functionality in their MUXMODE 0 can be used. No other UART configuration allows booting from the UART.
- HS USB boot: If the internal USB transceiver of a supported power-management IC is used, the IC's configuration interface must be connected to the device through I²C1. No other I²C interface is supported for this purpose. If other USB transceiver is used, the ROM code assumes it is powered, clocked, and out of reset.

26.3 Power, Clocks, and Reset Power-Up Sequence

See [Chapter 3, Power, Reset, and Clock Management](#), section *Power-Up Sequence*, for the power-on sequence, including power supplies, clocks, and reset signals.

26.4 Device Initialization by ROM Code

This section describes high-level booting concepts and provides basic knowledge for booting on the device.

26.4.1 Booting Overview

CAUTION

To use the level 2 (L2) cache with the device, the ROM code provides three primitive services. These services are implemented in monitor mode and do not use any resources outside the MPU subsystem. The services are described below. To call a service, a register r12 must be set to service ID and the SMI instruction must be executed.

- r12=1: To use the L2 cache, all L2 line data must be invalidated through the CP15 registers. This service invalidates the entire L2 cache and must be performed after a POR or a loss of L2 cache after reset. This register can also be read.
- r12=2: This service writes the value of the central processing unit (CPU) register R0 in the L2 cache auxiliary control register. This register can also be read.
- r12=3: This service writes the value of the CPU register R0 in the auxiliary control. This register can also be read. For more information about ARM L2 cache and registers, see the *Cortex-A8 Technical Reference Manual*. For more information about ARM CP15 registers, see the *ARM Architecture Reference Manual*.

NOTE: When the ROM Code branches to the first instruction of a GP device Initial software, the L2 cache is disabled.

26.4.1.1 Booting Types

Bootstrapping is the process of starting a bootstrap from one of the booting memories.

The ROM code has two booting functions: peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART or USB, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the device. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. After the image is burned, a software reset can be performed.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory or memory cards and executes it. This process is normally performed after cold or warm device reset.

The ROM code detects whether the device should download software from a peripheral interface (HS USB or UART 3) by using the sys_boot pin configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

NOTE: After reset release, the ROM code tries to boot from several interfaces, one after the other until it finds a bootable one. These interfaces (GPMC, MMC1, MMC2, USB, and UART) are selected in a specific order defined by the sys_boot settings.

As a consequence, if the first bootable interface found by the ROM code is not the first one in the list, some activity occurs on the interfaces tested before the bootable interface. This should be considered in case these intermediary interfaces are connected to other peripherals for some other purposes (an LED connected to a GPMC pad muxed internally to a GPIO for instance).

[Table 26-6](#) lists the pin multiplexing according to boot peripheral.

Table 26-6. Pin Multiplexing According to Boot Peripheral

Boot Device	Pins
NAND/OneNAND	General-purpose memory controller (GPMC) pins in mode 0
XIP memory	GPMC pins in mode 0
DiskOnChip	GPMC pins in mode 0
MMC/SD1	MMC1 pins in mode 0
MMC/SD2	MMC2 pins in mode 0
UART3	UART3 pins in mode 0
HS USB	HSUSBO pins in mode 0

CAUTION

- **UART boot:** UART3 is the only possible UART from which boot can be performed. Additionally, only UART3 pins that provide UART3 functionality in their MUXMODE 0 can be used. No other UART configuration allows booting from the UART.
- **HS USB boot:** If the internal USB transceiver of a supported power-management IC is used, the IC's configuration interface must be connected to the device through I²C1. No other I²C interface is supported for this purpose. If other USB transceiver is used, the ROM code assumes it is powered, clocked, and out of reset.

26.4.1.2 Main Features

The ROM code architecture is shown in [Figure 26-5](#). The ROM code is made up of several modules:

- The start-up module takes care of basic system configuration and dispatches control to the booting module.
- The clock detection module supports startup by detecting the system clock frequency.
- The booting module uses several device drivers to boot from an external device.
- The device drivers implement device protocols and perform logical operation on a device. They are abstracted from interface hardware by several interface drivers, which are responsible for interacting with hardware interface facilities.
- The interrupt handler module provides services used by all modules. It allows registering interrupt service routines (ISRs) and calls them when an interrupt occurs.

[Figure 26-5](#) shows each module.

Figure 26-5. ROM Code Architecture

26.4.2 Memory Map

26.4.2.1 ROM Memory Map

Figure 26-6 shows the ROM memory map.

Figure 26-6. 32KB ROM Memory Map

- ROM exception vectors

Exceptions are redirected to ROM exception vectors (see [Table 26-7](#)). The reset exception is redirected to the public ROM code startup. Other exceptions are redirected to RAM handlers by loading appropriate addresses in the PC register.

Table 26-7. ROM Exception Vectors

Address	Exception	Content
14000h	Reset	Branch to the public ROM code startup
14004h	Undefined	PC = 4020FFC8h
14008h	Software interrupt (SWI)	PC = 4020FFCCh
1400Ch	Prefetch abort	PC = 4020FFD0h
14010h	Data abort	PC = 4020FFD4h
14014h	Unused	PC = 4020FFD8h
14018h	IRQ	PC = 4020FFDCh
1401Ch	FIQ	PC = 4020FFE0h

- ROM code cyclic redundancy check (CRC)

The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 14000h – 1BFFFh. The 4-byte CRC code is stored at location 14020h.

- Dead loops

Dead loops are branch instructions coded in ARM mode. They have multiple purposes (see [Table 26-8](#)).

Table 26-8. Dead Loops

Address	Purpose
14080h	Undefined exception default handler
14084h	SWI exception default handler
14088h	Prefetch abort exception default handler
1408Ch	Data abort exception default handler
14090h	Unused exception default handler
14094h	IRQ exception default handler
14098h	FIQ exception default handler
1409Ch	Validation tests Pass
140A0h	Validation tests Fail
140A4h	Booting failed: No more booting devices
140A8h	Image not executed or returned
140ACh	Reserved
140B0h	Reserved
140B4h	Reserved
140B8h	Reserved
140BCh	Reserved

The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked with RAM exception vectors.

Dead loops can be called directly from code, but there is also a special function called from ROM code to execute a dead loop. This function is at address 140C0h. The function is assembly code in ARM mode, which takes the dead loop address from the R0 register. The main purpose of the function is to issue a global software reset before going to a dead loop. In addition, the function clears the global cold reset status before issuing the global software reset.

- Code

This space is used to keep code.

- Code and data

This space is used to keep code and other data.

- ROM code version

The ROM code version consists of two decimal numbers: major and minor. The major number is 18. The minor number identifies the ROM code version. The minor number is not aligned with the ROM code release number, but it can identify it. The ROM code version is coded as hexadecimal readable values (for example, ROM version 18.04 is coded as a 32-bit word: 00001804h).

26.4.2.2 RAM Memory Map

Figure 26-7 shows the RAM memory map. The partitioning of the on-chip SRAM shown in Figure 26-7 is used only during the booting process.

Figure 26-7. 64KB RAM Memory Map of GP Devices

- Downloaded image
This space is used by the public ROM code to store a downloaded booting image.
- Public stack
This space is reserved for stacks.
- Tracing data
The public ROM code tracing data is described in [Table 26-9](#). More information about ROM code tracing can be found in [Section 26.4.9, Tracing](#).

Table 26-9. Tracing Data

Address	Size [Bytes]	Description
0x4020FFB0	4	Current tracing vector, word 1
0x4020FFB4	4	Current tracing vector, word 2
0x4020FFB8	4	Current copy of the PRM_RSTST register (reset reasons)
0x4020FFBC	4	Cold reset run tracing vector, word 1
0x4020FFC0	4	Cold reset run tracing vector, word 2
0x4020FFC4	4	Reserved

- RAM exception vectors

The RAM exception vectors provide an easy way to redirect exceptions to the custom handler. [Table 26-10](#) shows the contents of the RAM space reserved for RAM vectors. The first seven addresses are ARM instructions that load into the PC the value in the next seven addresses. These instructions are executed when an exception occurs, because they are called from ROM exception vectors. By default, all exceptions are redirected to the exception dead loops. Users can redirect an exception to another handler by writing its address to the appropriate position from 0x4020FFE4 to 0x4020FFFC, or by overriding instructions between addresses from 0x4020FFC8 to 0x4020FFE0.

Table 26-10. RAM Exception Vectors

Address	Exception	Content
0x4020FFC8	Undefined	PC = [0x4020FFE4]
0x4020FFCC	SWI	PC = [0x4020FFE8]
0x4020FFD0	Prefetch abort	PC = [0x4020FFEC]

Table 26-10. RAM Exception Vectors (continued)

Address	Exception	Content
0x4020FFD4	Data abort	PC = [0x4020FFF0]
0x4020FFD8	Unused	PC = [0x4020FFF4]
0x4020FFDC	IRQ	PC = [0x4020FFF8]
0x4020FFE0	FIQ	PC = [0x4020FFFC]
0x4020FFE4	Undefined	0x14080
0x4020FFE8	SWI	0x14084
0x4020FFEC	Prefetch abort	0x14088
0x4020FFF0	Data abort	0x1408C
0x4020FFF4	Unused	0x14090
0x4020FFF8	Interrupt request (IRQ)	0x14094
0x4020FFFC	Fast interrupt request (FIQ)	0x14098

26.4.3 Overall Booting Sequence

Figure 26-8 is the ROM code flow chart.

Figure 26-8. Overall Booting Sequence

init-007

The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code performs the following steps:

- Step 1. Basic configurations and initializations.
- Step 2. The path named fast external boot is a special low-latency boot mode. It consists of a blind jump to the external addressable memory as soon as possible.
- Step 3. A booting device list is created (see [Section 26.4.4.3, Booting Device List Setup](#)). The list consists of all booting devices to be searched for a booting image. The list is created based on the sys_boot pins and the software booting configuration described in [Section 26.4.4.4, Software Booting Configuration](#). The software booting configuration structure is in the scratchpad memory and can be written by software before executing a software reset. The scratchpad memory is an internal RAM memory that keeps its contents as long as the power is supplied and is not influenced by wakeups or resets. After a software reset, the software booting configuration has priority over the sys_boot pin configuration.
- Step 4. After the booting device list is set, the booting procedure examines the booting devices on the list serially and executes memory booting or peripheral booting, depending on current booting device type:
 - Memory booting is executed when the booting device is permanent: XIP memory, NAND, DiskOnChip, OneNAND/Flex-OneNAND, or MMC/SD cards.
 - Peripheral booting is executed when booting device is temporary: UART or USB.
- Step 5. Memory booting reads data from memory type booting devices. Memory booting is described in detail in [Section 26.4.7, Memory Booting](#).
- Step 6. Peripheral booting downloads data from communication interfaces. The ROM code uses a simple logical protocol with peripheral booting. First, the device sends an ASIC-ID structure to inform the host about the peripheral booting start. The host responds by sending a booting message that can have one of three meanings:
 - Skip peripheral booting.
 - Continue peripheral booting.
 - Change the booting device.
 If the message is to continue, the host sends the entire image preceded by its size. Peripheral booting is described in [Section 26.4.5, Peripheral Booting](#).
- Step 7. For this booting device, the image is automatically started.

An additional feature of the booting module is the execution of the configuration header (CH). The CH configures the system for faster and more flexible booting from the selected permanent booting device. The CH, which is optional, is described in [Section 26.4.8.2, Configuration Header](#).

26.4.4 Startup and Configuration

26.4.4.1 Startup

The ROM code starts at address 0x0001 4000.

26.4.4.2 Clocking Configuration

The ROM code detects the system input clock frequency. The supported frequencies are:

- 12 MHz
- 13 MHz
- 16.8 MHz
- 19.2 MHz
- 26 MHz
- 38.4 MHz

After detecting the input clock, the ROM code configures the clocks and DLLs required for ROM code execution.

The configured DPLLS are:

- Peripheral DPLL, set to provide 96 MHz and 48 MHz for peripheral blocks
- MPU DPLL, set to provide 96 MHz for the Cortex-A8 MPU
- Core DPLL, set to provide 192, 96, 48, or 24 MHz for various blocks, such as interconnect, clocked by this DPLL output

The multipliers and dividers of the DPLLS are set to values which depend on the input clock detected.

[Table 26-11](#) summarizes the ROM code default settings for key clocks.

Table 26-11. ROM Code Default Clock Settings

Clock	Frequency [MHz]	Source
CORE.CLOCK	192	CORE DPLL output
L3x2.CLOCK	192	CORE.CLOCK
L3.ICLK	96	CORE.CLOCK/2
L4.ICLK	48	L3.ICLK/2
RM clock	24	L4.ICLK/2
MPU	96	CORE.CLOCK/2 (MPU DPLL in bypass)

The DPLLS and other settings are configured by default after each type of reset to give the ROM code the same working conditions. However, it is possible to override the default clock settings by means of the software booting configuration; for details, see [Section 26.4.4.4, Software Booting Configuration](#).

There are three ways to change DPLLS and all related clock divider, gating, and multiplexer configurations during the boot:

- ROM code default settings, described in this paragraph
- Software booting configuration after a software reset, described in [Section 26.4.4.4, Software Booting Configuration](#)
- CH, described in [Section 26.4.8.2, Configuration Header](#). This configuration can be blocked by the software booting configuration; this is possible during the memory booting. The CH lets the user have a known configuration (about GPMC, SDRC, and clock registers) after memory booting.

26.4.4.3 Booting Device List Setup

The ROM code creates a booting device list based on two sources:

- The software booting configuration is stored in the scratchpad memory.
- The sys_boot[5:0] pins are used to index the booting device table from which the list of booting devices is extracted.

[Figure 26-9](#) shows how the ROM code sets up the booting device list depending on the reset source.

NOTE: Only permanent booting devices are put on the list when reset is not power on and booting devices are taken from the sys_boot pins. Users can force peripheral booting after software reset using software booting configuration.

Figure 26-9. Booting Device List Setup

26.4.4.4 Software Booting Configuration

The software booting configuration is stored in the special scratchpad memory, which is not cleared after resets or wakeups. The software booting configuration is a simple structure at the address stored at the first location of available scratchpad memory: 0x48002910. [Table 26-12](#) shows the software booting configuration. There are two sections in this structure:

- The first section provides booting devices for the booting device list.
- The second section provides clock settings, which are applied before booting.

The sections are not mandatory and their order is not important. The ROM code searches for the next section at the location based on the size filled in the previous section. The clock configuration from software booting configuration overwrites the CH settings.

Table 26-12. Software Booting Configuration Structure

Field	Size [bytes]	Description
Boot Configuration		
Section 1 key	4	Synchronization key for section 1: 0xCF00AA01
Section 1 size	4	Size of section 1: 0x0000000C (12)

26.4.5 Peripheral Booting

26.4.5.1 Overview

The ROM code can boot from two different peripherals:

- HS USB: HS USB interface
- UART 3: Baud rate 115.2 Kbps, 8 bits, even parity, 1 stop-bit

The purpose of booting from a peripheral is to boot from an external host, such as a PC. This booting method is used primarily for programming flash memories connected to the device. The protocol is common to all peripherals. Some minor exceptions are described in the following sections. The common peripheral booting protocol is shown in [Figure 26-10](#).

Figure 26-10. Common Peripheral Booting Protocol

The ROM code first initializes the interface and sends a message called ASIC-ID to a host. The content of this message is summarized in [Table 26-13](#). The host uses this message to send only appropriate data to the device according to the identification codes sent.

The ROM code waits 300 ms for an answer from UART and 3 s from USB host. If a time-out occurs, the peripheral booting returns to the main booting procedure with TIMEOUT status.

Table 26-13. ASIC-ID Structure

ASIC-ID Item	Size [Bytes]	Description
Items	1	Number of subblocks
ID subblock	7	Device identification information
Reserved for non-GP devices	4	Reserved
ID subblock	23	Identification data
Reserved for non-GP devices	23	Reserved
Checksum subblock	11	CRC (4 bytes)

The host can send different messages, as described in [Table 26-14](#). If the second or third message is not received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which determines the next booting device according to the boot message received.

If the first message is received without a time-out, the image size (a 32-bit word) and the image itself are expected to be received. The image is downloaded directly at address 0x40200000 in the internal RAM.

The ROM code waits up to 1 minute for completion. If the downloading procedure does not complete before this period, the peripheral booting fails. If the download passes, the peripheral booting succeeds and the image can be executed.

Table 26-14. Boot Messages

Message Name	Value	Description
Peripheral boot	0xF0030002	Continue peripheral booting.
Change booting device	0xF003XX06	Skip current peripheral booting and continue booting from booting device type indicated by XX: 0x00: Void, no booting device 0x01: XIP memory 0x02: NAND 0x03: OneNAND 0x04: DOC 0x05: MMC/SD2 0x06: MMC/SD1 0x07: XIP memory with wait monitoring 0x08: MMC/SD2 Hybrid connection 0x09..0x0F: Reserved 0x10: UART 0x11: HS USB Others: Reserved
Next booting device	0xFFFFFFFF	Skip current booting device and move to the next booting device on the device list.
Memory booting	Others	Skip current peripheral booting and move to the first booting device for memory booting.

Figure 26-11 shows the peripheral booting procedure.

Figure 26-11. Peripheral Booting Procedure

init-010

26.4.5.2 UART

The ROM code supports booting from a UART interface with the following characteristics:

- UART interface 3 at UART3 pins
- Communication parameters set to 115.2 Kbps, 8 bits, even parity, 1 stop-bit
- Two-pin interface: RX/TX with software flow control (XON/XOFF). The other UART pins are left at their default configuration.
- The UART wait for boot message time-out is 300 ms.

26.4.5.3 USB

The ROM code supports booting from a USB interface with the following characteristics:

- HS USB interface
- USB 2.0 transceiver macrocell interface (UTMI)+ low pin interface (ULPI) 8-bit data transceiver support (single data rate)
- Power IC detection and automatic configuration of its USB transceiver using I2C1
- The enumeration time-out is 3 seconds.
- The USB wait for boot message time-out is 3 seconds

The ROM code USB driver conforms with the USB 2.0 specification and the USB on-the-go (OTG) supplement. It supports transactions at HS (that is, 480 Mbps) and FS (that is, 12 Mbps). During peripheral booting, only the USB device functionality is used. The driver resides in the on-chip memory (OCM) ROM, which is small. The driver therefore contains the minimum functionality needed as a USB device and is not a full-fledged driver. It does not contain the functionality needed for a USB host. The device functionality of the USB OTG controller is used for the peripheral booting process in the ROM code.

26.4.5.3.1 USB Driver Descriptors

USB devices report their attributes using descriptors. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type. Using descriptors allows concise storage of the attributes of individual configurations so that each configuration can reuse descriptors or portions of descriptors from other configurations that have the same characteristics. Where appropriate, descriptors contain references to string descriptors. String descriptors contain displayable, human-readable information that describes a descriptor. These descriptor details can be used for tool development or debugging:

- Device descriptor

A device descriptor contains general information about a USB device, including information that applies globally to the device and all device configurations. A USB device has only one device descriptor.

Because the ROM code uses the HS feature of the USB core, a device-qualifier descriptor is required.

[Table 26-15](#) describes the device descriptors.

Table 26-15. Device Descriptor

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x01	Device descriptor type
bcdUSB	0x0210	USB specification release number in binary coded decimal (BCD) format
bDeviceClass	Vendor-specific (0xFF)	Class code
bDeviceSubClass	Vendor-specific (0xFF)	Subclass code
bDeviceProtocol	Vendor-specific (0xFF)	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
idVendor	0x0451	Vendor ID (TI default table)
idProduct	Device-specific (0xD00E)	Product ID (TI default table)

Table 26-15. Device Descriptor (continued)

Field	Value	Description
bcdDevice	0x0000	Device release number
iManufacturer	See values in Section 26.4.5.3.2.	Index of string descriptor describing manufacturer
iProduct	See values in Section 26.4.5.3.2.	Index of string descriptor describing product
iSerialNumber	See values in Section 26.4.5.3.2.	Index of string descriptor describing device serial number
bNumConfigurations	0x01	Number of possible configurations

- Device-qualifier descriptor

The device-qualifier descriptor contains information about a HS-capable device that changes if the device operates at its other speed. This descriptor is retrieved by the host using the GetDescriptor() request (standard device request). [Table 26-16](#) describes a device-qualifier descriptor.

Table 26-16. Device-Qualifier Descriptor

Field	Value	Description
bLength	0x0a	Size of this descriptor in bytes
bDescriptorType	0x06	Device-qualifier descriptor type
bcdUSB	0x0210	USB specification release number in BCD
bDeviceClass	0xFF	Class code
bDeviceSubClass	0xFF	Subclass code
bDeviceProtocol	0xFF	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
bNumConfigurations	0x01	Number of possible configurations
bReserved	0x00	Reserved for future use

- Configuration descriptor

This descriptor gives information about a specific device configuration. The descriptor describes the number of interfaces supported by the configuration. See [Table 26-17](#) for details.

Table 26-17. Configuration Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x02	Configuration descriptor type
wTotalLength	-	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xc0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Other speed configuration descriptor

This descriptor describes the configuration of a HS-capable device if it operates at its other possible speed. See [Table 26-18](#) for details.

Table 26-18. Other Speed Configuration Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x07	Other speed configuration descriptor type

Table 26-18. Other Speed Configuration Descriptor (continued)

Field	Value	Description
wTotalLength	-	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xc0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Interface descriptor

This descriptor describes a specific interface in a configuration. See [Table 26-19](#) for details.

Table 26-19. Interface Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x04	Interface descriptor type
bInterfaceNumber	0x00	Number of this descriptor
bAlternateSetting	0x00	Value to select the alternate setting
bNumEndpoints	0x02	Number of endpoints used for this interface
bInterfaceClass	0xFF	Class code
bInterfaceSubClass	0xFF	Subclass code
bInterfaceProtocol	0xFF	Protocol code
iInterface	Index	Index of string descriptor describing this interface

- Endpoint descriptor

Each endpoint used for an interface has its own descriptor. This descriptor contains information required by the host to determine the bandwidth requirements of each endpoint. This descriptor is returned as part of the GetDescriptor(Configuration) request. See [Table 26-20](#) and [Table 26-21](#) for details.

Table 26-20. BULK IN Endpoint Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x81 (1 IN)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See ⁽¹⁾ .	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

⁽¹⁾ The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

Table 26-21. BULK OUT Endpoint Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x01 (1 OUT)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See ⁽¹⁾ .	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

⁽¹⁾ The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

- String descriptors

String descriptors use UNICODE encoding. The strings in a USB device can support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a 16-bit language ID (LANGID) defined by the USB interface. String index 0 for all languages returns a string descriptor that contains an array of 2-byte LANGID codes supported by the device.

See the tables describing string descriptors:

- The language ID string descriptor ([Table 26-22](#))
- The manufacturer ID string descriptor ([Table 26-23](#))
- The product ID string descriptor ([Table 26-24](#))
- The configuration string descriptor ([Table 26-25](#))
- The interface string descriptor ([Table 26-26](#))

Table 26-22. Language ID String Descriptor

Field	Value	Description
bLength	0x04	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
wLangId	0x0409 (US English)	Language ID code

Table 26-23. Manufacturer ID String Descriptor

Field	Value	Description
bLength	0x24	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	Texas Instruments	Manufacturer string

Table 26-24. Product ID String Descriptor

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	Multimedia device or specific vendor string	Product string (Device specific)

Field	Value	Description
bLength	0x08	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	pbc	Configuration string

Table 26-26. Interface String Descriptor

Field	Value	Description
bLength	0x08	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	pbi	Interface string

26.4.5.3.2 USB Customized Descriptors

There are two parameters in USB descriptors that customers can define after the chip is created: vendor ID (VID) and product ID (PID). The ROM code uses dedicated eFuses that hold VID and PID values. Other parameters can also be changed based on VID value. The ROM code has an encoded set of parameters for customers who have defined their requirements before the ROM code has been done. [Table 26-27](#) lists the parameters that depend on VID value.

Table 26-27. Customized Descriptor Parameters

Parameter	Size [Bytes]	Default Values	TI Default Values
Device ID code	2	0x0000	0x0000
Device class	1	0xFF	0xFF
Device subclass	1	0xFF	0xFF
Device protocol	1	0xFF	0xFF
Manufacturer	String	N/A	Texas Instruments
Product	String	Multimedia device or specific vendor string	Multimedia device or specific vendor string
Serial number	String	See ⁽¹⁾	See ⁽¹⁾

⁽¹⁾ The Standard device descriptor indicates that the device has no serial number.

[Figure 26-12](#) describes an additional customer parameter selection method. It is based on the VID burned in the USB eFuses.

Figure 26-12. Customer USB Descriptor Selection

init-011

26.4.5.3.3 USB Driver Functionality

- Transactions supported

The following transactions are supported:

- Control transactions: Used for standard device requests
- Bulk transactions: Used for data transfer in the image downloading stage. The ASIC-ID is sent on the Bulk IN endpoint and the image is transferred over the Bulk OUT endpoint from the host.

The USB first attaches to the host as an FS device. In the reset mechanism, the USB core requests HS operation. If the HS negotiation in the reset phase is successful, further transactions are at HS; otherwise, they are at FS. After reset, the USB driver checks for the speed of the device, whether it is FS or HS. Depending on the speed configured by the host, the standard USB device requests are responded to with the corresponding descriptors.

- Standard device request restrictions

Because the USB driver is used only by the ROM code for peripheral booting, some standard device requests are not supported by the driver. [Table 26-28](#) lists the standard device requests supported by the driver.

Table 26-28. Standard Device Requests Supported

Request	Description	Support
CLEAR_FEATURE	Sets/clears a specific feature	Supported only for ENDPOINT_HALTED feature
GET_CONFIGURATION	Returns the current device configuration value	Yes
GET_DESCRIPTOR	Returns the specified descriptor	Yes
GET_INTERFACE	Returns the selected alternate setting for the specified interface	Yes
GET_STATUS	Returns the status for the specified recipient	Yes
SET_ADDRESS	Sets the device address	Yes
SET_CONFIGURATION	Sets the device configuration	Yes
SET_DESCRIPTOR	Updates existing descriptors or adds new descriptors	No. Runtime updating of descriptors is not supported.
SET_FEATURE	Sets or enables a specific feature	Supported only for ENDPOINT_HALTED feature
SET_INTERFACE	Selects an alternate setting in an interface	No. Runtime setting of alternate features is not supported.
SYNCH_FRAME	Sets and reports an endpoint synchronization frame	No, because isochronous transfers are not used

26.4.6 Fast External Booting

26.4.6.1 Overview

The fast external boot is a special memory booting mode. It is a blind jump to a code in an external XIP device connected to chip-select 0 (CS0). Fast external booting lets customers create their own booting code.

The jump is performed with minimum on-chip ROM code execution.

26.4.6.2 External Booting

[Figure 26-13](#) shows the fast external boot procedure. The code is at the beginning and is written in assembly. The code does not use any RAM.

Figure 26-13. Fast External Boot Procedure

26.4.7 Memory Booting

26.4.7.1 Overview

The memory booting process starts an external code in memory type booting devices. Because the device always uses the memory type booting devices for booting, they are called permanent booting devices. The supported permanent booting devices are:

- All NOR devices up to 2 Gb (256M bytes)
- NAND devices from 64Mb
- OneNAND/Flex-OneNAND devices from 512Mb
- SD/MMC/eSD/eMMC flash cards with **active** primary partition of type FAT12/16/32 or with raw data
- DiskOnChip H3 devices

Two main groups of permanent booting devices are distinguished by code shadowing. Code shadowing means copying a code from a nondirectly addressable memory device (non-XIP) to RAM, where the code can be executed. Directly addressable memory devices are XIP devices.

[Figure 26-14](#) is the general memory booting procedure common to all types of booting devices. First, the CH is copied to internal RAM. It is copied even for XIP booting devices, because the device can temporarily lose a connection with XIP memory during CH execution. The second step is to shadow the image, if the booting device is not XIP. The last step is image execution.

Unsuccessful execution or return from image results in a dead loop.

If CH copying or shadowing fails, memory booting returns to the main booting procedure, which selects the next booting device for booting.

Figure 26-14. Memory Booting Procedure

init-014

26.4.7.2 Non-XIP Memory

[Figure 26-15](#) shows the procedure used when memory booting runs with non-XIP booting devices. The grayed procedures are specific to each booting device. NAND and OneNAND/Flex-OneNAND booting devices use up to four copies of the image in the first four physical blocks. Therefore, the ROM code searches for the image in the first four physical blocks of these booting devices. Other booting devices use only one copy of the image and the block loop runs only once.

During image shadowing on a GP device, the CH is expected to be in a separate sector before the initial software.

Figure 26-15. Detailed Memory Booting for Non-XIP Booting Devices

Table 26-29 summarizes numbers of blocks and sectors that are searched during memory booting from devices requiring image shadowing. NANDs and OneNAND/Flex-OneNAND are organized with blocks, which are erasable units. DOC memory reserves only one block for booting, which overlaps the XIP part. MMC/SD+FAT card booting consists of reading a file. Because there is only one file read, it can be considered one block trial. When no file system is present the first sectors of two blocks (128KB each) are searched.

Table 26-29. Blocks and Sectors Searched on Non-XIP Memories

Memory	Maximum Number of Checked Blocks	Number of Sectors Searched
NAND	First 4	Number of sectors in a block ⁽¹⁾
OneNAND/Flex-OneNAND	First 4	8
DOC ⁽²⁾	1	4
MMC/SD + FAT system	1 file	
MMC/SD raw	2	1

⁽¹⁾ Depends on NAND type

⁽²⁾ Because XIP booting always precedes DOC booting and the same data is used for XIP areas, the DOC memory image must contain the first sector filled with 0xFF or 0x00. Therefore, a void sector at the beginning makes XIP booting fail and moves to DOC booting.

The following sections describe the supported booting device types.

For more information about the GPMC module, see [Chapter 10, Memory Subsystem](#).

26.4.7.3 XIP Memory

The ROM code can boot directly from XIP booting devices, such as NOR flash memories, that have the following characteristics:

- The GPMC is the communication interface.
- Memories up to 2 Gb (256MB) can be connected.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- The GPMC clock is 48 MHz.
- The booting device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is monitored according to the sys_boot configuration pins.

Depending on the sys_boot option, the GPMC can be configured to use the wait signal connected to the gpmc_wait0 pin. Wait pin polarity is set to stall accessing memory when gpmc_wait0 is low. Wait monitoring is used with memories that require a long time for initialization after reset, or that must pause while reading data. An example of such memory is DiskOnChip.

For an XIP memory booting, no user intervention is needed; the following steps are described for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next booting device.

Boot from an XIP booting device consists of the following steps:

1. Configure the GPMC for XIP booting device access.
2. Verify that the CH is present at address 0x0800 0000. If it is, copy the entire sector (512 B) to internal RAM and execute the CH.
3. Set the image location:
 - 0x0800 0000 if the CH is not found
 - 0x0800 0200 if the CH (512 bits) is found
4. Verify that a bootable image is at the image location.
5. Execute the image if it is found.
6. If the image is not found, return from XIP booting to the main booting loop.

26.4.7.3.1 GPMC Initialization

[Table 26-30](#) describes the timing settings of GPMC set for XIP and other address-data accessible booting devices, like DiskOnChip or OneNAND/Flex-OneNAND. [Table 26-30](#) is included for debug information.

Table 26-30. XIP Timing Parameters

Parameter	Value [Clock Cycles]	Register Initialization (where i = 0...7)	Reset Value
Write cycle time	17	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x11.	0x11
Read cycle time	17	The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x11.	0x11
CS low time	1	The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x1.	0x1
CS high time	16	The GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field is set to 0x10.	0x10
ADV low time	1	The GPMC_CONFIG3_i[3:0] ADVONTIME bit field is set to 0x1.	0x1
ADV high time	2	The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field is set to 0x2.	0x2
OE low time	3	The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x3.	0x3

Table 26-30. XIP Timing Parameters (continued)

Parameter	Value [Clock Cycles]	Register Initialization (where i = 0...7)	Reset Value
OE high time	16	The GPMC_CONFIG4_i[12:8] OEOFETIME bit field is set to 0x10.	0x10
WE low time	3	The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3.	0x03
WE high time	15	The GPMC_CONFIG4_i[28:24] WEOFETIME bit field is set to 0xF.	0x10
Data latch time	15	The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xF.	0x0F

26.4.7.4 NAND

NAND flash memory is not an XIP booting device; it requires shadowing before the code can be executed. ROM code support for the NAND flash booting devices has the following characteristics:

- The GPMC is the communication interface.
- Device from 64 Mb (8MB)
- x8 and x16 bus width
- Small page size (512 bytes + 16 bytes), large page size (2048 bytes + 64 bytes), and very large page size (4096 bytes + 128 bytes)
- Chip enable (CE) don't care booting devices only
- Single level cell (SLC) and multilevel cell (MLC) devices
- Device identification is based on standard identification data or ID2 protocol.
- One-bit error checking and correction (ECC) is used to protect a 512-byte sector.
- GPMC timings are adjusted for NAND access.
- The GPMC clock is 48 MHz.
- The booting device is connected to CS0.
- The wait pin signal gpmc_wait0 is connected to the NAND BUSY output.
- Four physical blocks are searched for image. Block size depends on the booting device.

For NAND memory booting, no user intervention is needed; the information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next booting device for booting.

26.4.7.4.1 Initialization and NAND Detection

The initialization routine for NAND consists of three parts: GPMC initialization, booting device detection with parameter determination, and bad block detection/verification.

- GPMC initialization

The GPMC interface is configured so that it can access NANDs. Because NANDs do not need the address bus, it is released. The data bus width is initially set to 8 bits. If necessary, it is changed to 16 bits after the booting device parameters are determined. [Table 26-31](#) shows the GPMC configuration used during NAND boot. [Table 26-31](#) is included for debug information.

Table 26-31. NAND Timing Parameters

Parameter	Value [Clock Cycles]	Register Initialization (where i = 0...7)	Reset Value
Write cycle time	20	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x14.	0x11
Read cycle time	20	The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x14.	0x11
CS low time	0	The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x0.	0x1

Table 26-31. NAND Timing Parameters (continued)

Parameter	Value [Clock Cycles]	Register Initialization (where i = 0...7)	Reset Value
OE low time	5	The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x5.	0x3
OE high time	16	The GPMC_CONFIG4_i[12:8] OEOFETIME bit field is set to 0x10.	0x10
WE low time	3	The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3.	0x3
WE high time	15	The GPMC_CONFIG4_i[28:24] WEOFETIME bit field is set to 0xF.	0x10
Data latch time	14	The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xE.	0xF

- Booting device detection and parameters

The ROM code must first identify the NAND type connected on the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND booting device is reset and its status is polled until it is ready for operation, then the Read ID command is issued. If the Read Device ID is recognized as a supported booting device, the booting device parameters are extracted from an internal ROM code table. [Table 26-32](#) lists the supported NAND devices.

Table 26-32. Supported NAND Devices

Capacity	Device ID	Bus Width	Page Size in Bytes
64Mb	E6h	8	512
128Mb	33h	8	512
128Mb	73h	8	512
128Mb	43h	16	512

16Gb	D5h	8	2048 (4096)
16Gb	B5h	16	2048 (4096)
16Gb	C5h	16	2048 (4096)
32Gb	A7h	8	2048 (4096)
32Gb	B7h	16	2048 (4096)
64Gb	AEh	8	2048 (4096)
64Gb	BEh	16	2048 (4096)

After retrieving parameters from the table, page size and block size are updated based on the fourth byte of the NAND ID data. Because of inconsistency among manufacturers, only NAND devices recognized to be at least 2Gb have these parameters updated. Therefore, the ROM code supports 4-KB page NAND devices, but only if their size, according to [Table 26-32](#), is at least 2Gb. NAND devices smaller than 2Gb have the block size parameter set to 32KB when the page size is 512 bytes and to 128KB when the page size is 2048 bytes. [Table 26-33](#) shows the fourth ID data byte encoding used in the ROM code.

Table 26-33. Fourth NAND ID Data Byte

Item	Description	I/O Number							
		7	6	5	4	3	2	1	0
Page Size	512 bytes							0	0
	2048 bytes							0	1
	4096 bytes							1	0
	8192 bytes							1	1
Block Size	64KB		0	0					
	128KB		0	1					
	256KB		1	0					
	512KB		1	1					

The detection procedure is described in [Figure 26-16](#). If the device ID is not recognized, the ROM code tries to read ID2 from the booting device; the sequence is described in [Figure 26-17](#). The description of the ID2 data content is summarized in [Table 26-34](#). If the ROM code fails to identify booting device ID or ID2, it returns with FAIL. When the booting device is successfully detected, the ROM code changes the GPMC to 16-bit bus width if necessary.

- Bad block detection/verification

Invalid blocks contain invalid bits whose reliability cannot be ensured by the manufacturer. These bits are identified in the factory or during the programming and reported in the initial invalid block information in the spare area on the first and second page of each block. Because the ROM code looks for an image in the first four blocks, it detects the validity status of these blocks. Blocks detected as invalid are not accessed later. Block validity status is coded in the spare areas of the first two pages of a block. [Table 26-35](#) lists the validity status coding for the four NAND families.

Table 26-35. Bad Block Mark Locations in NAND Spare Areas

	Small Page NAND	Large Page NAND
8-bit NAND device Block invalid when any byte does not equal FFh	6th byte in 1st page	1st byte in 1st page
	6th byte in 2nd page	1st byte in 2nd page
16-bit NAND device Block invalid when any word does not equal FFFFh	1st word in 1st page	1st word in 1st page
	6th word in 1st page	1st word in 2nd page
	1st word in 2nd page	
	6th word in 2nd page	

Figure 26-18 shows the invalid block detection routine. The routine consists in reading spare areas and checking data according to the conditions listed in Table 26-35. The flags are used internally to give information about the validity of each block.

Figure 26-18. Bad NAND Invalid Block Detection

26.4.7.4.2 SLC NAND Read Sector Procedure

During the booting procedure, the ROM code reads 512-byte sectors from the NAND device. The reading fails in two cases:

- The accessed sector is in a block marked as invalid.
- The accessed sector contains an error that cannot be corrected with ECC.

Pages can contain errors caused by memory alteration (1 error bit/sector maximum). The ROM code uses ECC to correct those errors. The ECC algorithm, based on Hamming codes, is used on 512-byte sectors to generate 3 bytes. They are generated by the GPMC hardware on each read cycle. The computed ECC is compared to the ECC stored in the spare area of the corresponding page. Depending on the number of sectors per page (small pages and large pages), several ECC data are stored in the spare area of the page. If the computed ECC data and the stored ECC data are equal, the read sector function returns the read 512-byte sector without error. Otherwise, the ROM code tries to correct the error in the sector and returns the data, if successful. If there are uncorrectable errors, the ROM code returns with FAIL.

[Figure 26-19](#) shows the ECC locations in NAND spare areas.

Figure 26-19. ECC Locations in NAND Spare Areas

init-035

For large page NAND memories, the spare area contains four ECC sets, each for a 512-byte sector within the 2048-byte page. Sectors are tagged A, B, C, and D. [Table 26-36](#) shows parity bit locations inside ECC bytes.

Table 26-36. Hamming Code Parity Bit Locations

Byte	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
ECC-x[0]	128-2	64-2	32-2	16-2	8-2	4-2	2-2	1-2
ECC-x[1]	128-1	64-1	32-1	16-1	8-1	4-1	2-1	1-1
ECC-x[2]	2048-1	1024-1	512-1	256-1	2048-2	1024-2	512-2	256-2

The 4-KB page NAND memories have eight ECC sectors tagged A to H. [Figure 26-20](#) shows the spare area organization for such NANDs.

26.4.7.4.3 MLC NAND Read Sector Procedure

Multilevel cell (MLC) NANDs have a bigger bit error rate than single-level cell (SLC) NANDs. As a consequence, reading data from MLC NANDs requires a stronger error correction capability. Usually, NAND manufacturers recommend Bose-Chaudhuri-Hocquenghem (BCH) code, which can correct 4- or 8-bit errors in 512-byte data sectors. Because of the specific MLC implementation in the device, which is not fully hardware-based, ROM code cannot implement sector BCH encoding. Therefore, ROM code supports MLC booting using its proprietary error correction scheme. This error correction scheme is a combination of BCH, checksum, and redundancy techniques.

26.4.7.4.3.1 MLC Mode Detection

The ROM code verifies whether the block is programmed in MLC mode before reading data from each block. If MLC mode is detected, bad block verification is not performed and the block is considered to be valid. If a user intends a block to be omitted, it should be left erased, which consequently will cause the ROM code to fail in reading data and skipping to the next block.

MLC mode detection consists in reading fifteen 32-bit words of BCH-encoded data and checking whether they match the special encoding scheme described in the following section. The MLC mode is switched on if at least five words match the encoding scheme without errors.

26.4.7.4.3.2 Data Encoding

The plain booting image must be formatted in a special way before being flashed:

1. Checksum modulo 16 is calculated, which means all 256 16-bit words are summed.
2. The checksum result and three empty words of padding are added at the end.
3. A sector is represented by 260 words, 16 bits each.
4. All 16-bit words are converted into 32-bit words by adding 12 bits of the BCH result and 4-bit zero padding.

Figure 26-21 shows how a sector of image data is processed.

Figure 26-21. MLC NAND Data Encoding

init-037

The BCH algorithm has the following characteristics:

- 32,20,2 – 32-bit message, 20-bit data, 2-bit error correction capability
- GF polynomial generator: $p(x) = X^6 + X^5 + 1$
- Generator polynomial: $g(x) = X^{12} + X^9 + X^8 + X^7 + X^4 + X^2 + 1$

The 2 bytes of data, that is a 16-b word, are encoded as follows:

Input byte stream: Byte0, Byte1, Byte3,
Byte4, ...

Output byte stream: $\text{BCH}[3..0]$,
 $\text{BCH}[11..4]+0000b$, Byte0, Byte1, $\text{BCH}[3..0]$, $\text{BCH}[11..4]+0000b$, Byte3, Byte4, ...

26.4.7.4.3.3 Flash Layout

The 1040-encoded sectors are packed into a NAND space as shown in Figure 26-22. Encoded sectors are located serially, without gaps. The area named "Not Programmed" is not read by ROM code. Each encoded sector is put in twice. This redundancy is required to achieve the necessary booting reliability.

Figure 26-22. MLC NAND Page Layout

init-038

26.4.7.5 OneNAND/Flex-OneNAND

ROM code support for OneNAND/Flex-OneNAND devices has the following characteristics:

- Devices from 512Mb
- The GPMC is the communication interface.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- GPMC reset default timings are used.
- The GPMC clock is 48 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is not monitored.
- Four physical blocks are searched for image. The block size is 128KB.
- The ROM Code fully exploits the ECC controller embedded in the OneNAND/Flex-OneNAND devices themselves. The error code correction capability depends on this controller. ROM Code can support any existing and forecasted OneNAND/Flex-OneNAND devices.

The OneNAND/Flex-OneNAND device is a NAND matrix coupled with RAM buffers and a NOR-type interface. ECC correction handling is done automatically by the internal state-machine. The page to be accessed is first loaded in the RAM buffer using memory-mapped registers. Then, the page is read directly from the buffer using a NOR-type interface.

For OneNAND/Flex-OneNAND memory booting, no user intervention is needed. The information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

26.4.7.5.1 Initialization and OneNAND/Flex-OneNAND Detection

The initialization routine for OneNAND/Flex-OneNAND consists of two parts: GPMC initialization and booting device detection with parameter determination:

- GPMC initialization

The ROM code first initializes the GPMC interface the same way as for an XIP memory (that is, asynchronous 16-bit multiplexed mode). Wait signal monitoring is disabled. See [Table 26-30](#).

- OneNAND/Flex-OneNAND detection and parameters

The ROM code identifies a OneNAND/Flex-OneNAND device by reading its identification data.

There are two ways to read identification data: using serial commands and reading from fixed memory mapped registers. The ROM code reads identification data using both methods and compares the result. When the comparison passes, the ROM code assumes that the OneNAND/Flex-OneNAND device is connected. If the booting device is successfully recognized, the ROM code reads the booting device configuration (amount and size of data buffers) and configures it for asynchronous mode (default).

26.4.7.5.2 OneNAND/Flex-OneNAND Read Sector Procedure

When booting requests a sector from the OneNAND/Flex-OneNAND device, the ROM code issues the load operation, which transfers the content of the requested sector to the data buffer RAM. The ROM code waits until the operation completes, polling the OneNAND/Flex-OneNAND interrupt register. The status register is then checked and the ROM code returns FAIL if the operation completes with an error. Otherwise, the data buffer RAM is copied to the destination buffer. [Figure 26-23](#) shows this procedure.

Figure 26-23. OneNAND/Flex-OneNAND Read Sector

init-025

26.4.7.5.3 OneNAND/Flex-OneNAND Support Limitations

As described in [Section 26.4.7.5.1, Initialization and OneNAND/Flex-OneNAND Detection](#), the ROM code checks only the coherency of the device ID obtained by two different methods. There is no table of supported OneNANDs/Flex-OneNANDs in the ROM code. This removes any dependency of the ROM code on device IDs from different manufacturers. However, the driver works with the following assumption:

- Page size is assumed to be 2048 bytes, divided into four sectors of 512 bytes. In case of OneNAND/Flex-OneNAND, with pages of 4096 bytes, divided into eight sectors, users must program only the first sectors (sectors 0, 1, 2, 3) of each page. Sectors 4, 5, 6, and 7 of each page are not considered by the driver.

26.4.7.6 MMC/SD Cards

The ROM code supports MMC/SD cards, with some limitations:

- Supports MMC/SD cards compliant with the *Multimedia Card System Specification v4.2* from the MMCA Technical Committee and the *SD I/O Card Specification v 2 .0* from the SD Association. Includes high-capacity (size >2GB) cards: HC-SD and HC MMC
- 3-V power supply, 3-V I/O and 1.8-V I/O voltages on port 1
- Supports eMMC/eSD (1.8-V I/O voltage and 3.0-V Core voltage) on port 2. The external transceiver mode on port 2 is not supported.
- Initial 1-bit MMC mode, 4-bit SD mode
- Clock frequency:
 - Identification mode: 400 kHz
 - Data transfer mode: 20 MHz
- Only one card connected to the bus
- Raw mode, image data read directly from card sectors
- FAT12/16/32 support, with or without a master boot record (MBR).
- For a FAT (12/16/32)-formatted memory card, the booting file must not exceed 128 KB.
- For a raw-mode memory card, the booting image must not exceed 128 KB.

For MMC/SD memory booting, no user intervention is needed. The information in the following subsections is included for debugging. Failure in MMC/SD card detection causes a return to the main booting procedure, which selects the next booting device for booting.

The HS MMC/SD/SDIO host controllers (MMCHS) handle the physical layer, while the ROM code handles the simplified logical protocol layer (read-only protocol). A limited range of commands is implemented in the ROM code. The MMC/SD specification defines two operating voltages for standard or HS cards. The ROM code supports only standard operating voltage range (3 V) (both modes supported).

The ROM code reads a booting file from the card file system and boots from it. [Figure 26-24](#) shows the complete procedure.

Figure 26-24. MMC/SD Booting

init-016

26.4.7.6.1 Initialization and MMC/SD Card Detection

The ROM code initializes the card connected on interface 1 using the standard high-voltage range (3.0 V) if a card is plugged in. If no card is present, the ROM code goes to the next booting device. The standard identification process and relative card address (RCA) assignment are used. However, the ROM code searches for only one card connected on the bus. This is done using the CMD line common to the SD and MMC cards. The MMC and SD standards describe this phase as the initialization phase. They differ in the first commands, CMD1 and ACMD41. The ROM code uses this command difference to differentiate between MMC and SD cards; that is, CMD1 is supported only by MMC, and ACMD41 is supported only by SD. The ROM code first sends a CMD1 to the card and gets an answer only if an MMC card is connected. If no answer is received, ACMD41 (a combination of CMD55 and ACMD41) is sent, and an answer is expected from an SD card. If an answer is not received, no cards are connected and the ROM code exits MMC/SD booting with FAIL.

Figure 26-25 shows the MMC/SD detection procedure.

Figure 26-25. MMC/SD Detection Procedure

init-026

26.4.7.6.2 Read Sector Procedure

- Raw mode:

In raw mode, an image can be at offset 0 or 128KB and must not be bigger than 128KB. Raw mode is detected by reading sector 0 and sector 256. The content of these sectors is verified for the presence of a TOC structure. In the case of a GP device, a configuration header (CH) must be in the first sector followed by a GP header. The CH can be void (contains only a CHSETTINGS item for which the valid field is 0), as described in [Section 26.4.8.2, Configuration Header](#). Image data is read directly from continuous sectors of a card. If raw mode is not detected, file system mode is checked.

- File system handling:

The sector read procedure uses the standard MMC/SD read data procedure. The sector address is generated based on the booting memory file map collected during initialization. Thus, the ROM code can address sectors freely in the booting file space.

26.4.7.6.3 File System Handling

The MMC/SD cards can hold a file system that ROM code reads. The image used by the booting procedure is taken from a booting file named MLO. This file must be in the root directory on an active primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured as floppy-like or hard-drive-like:

- When acting like a floppy, the content of the card is a single FAT12/16/32 file system without an MBR holding a partition table.
- When acting like a hard drive, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary, and active.

According to the *MultiMediaCard FAT16 File System Specification* from the MMCA Technical Committee, the card must always hold an MBR, except for MMC cards using a floppy-like file system. However, depending on the operating system used, the MMC/SD card is formatted with or without partition(s) (using an MBR). The ROM code supports both types: floppy-like or hard-drive-like. The ROM code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector in the booting file without involving the ROM code FAT module. [Figure 26-26](#) shows the complete process.

Figure 26-26. SD/MMC Booting

init-027

26.4.7.6.3.1 MBR and FAT File System

This section describes the functions used by the ROM code to determine whether an MBR with a FAT is used. It is not intended to fully describe the MBR and the FAT file system detection and reading procedure. The ROM code can detect FAT12/16/32 allocation table types. It cannot boot on devices with NTFS or Linux® FS partitions. Some memory devices that support file systems can be formatted with or without MBR; therefore, the first task of the ROM code is to detect whether the booting device is holding an MBR in the first sector.

The MBR is the first sector of a memory device. It consists of executable code, four partition entries, and one signature. The aim of such a structure is to divide the hard disk in partitions used primarily to boot different systems (for instance, Microsoft Windows™). This structure is described in [Table 26-37](#); partition table entry is described in [Table 26-38](#).

Table 26-37. Master Boot Record Structure

Offset	Length (Bytes)	Entry Description
0000h	446	Optional code
01BEh	16	Partition table entry
01CEh	16	Partition table entry
01DEh	16	Partition table entry
01EEh	16	Partition table entry
01FEh	2	Signature (= 0xAA55)

Table 26-38. Partition Table Entry

Offset	Length (Bytes)	Entry Description	Value
0000h	1	Partition state	00h: Inactive 80h: Active
0001h	1	Partition start head	Hs
0002h	2	Partition start cylinder and sector	Cs[7:0]–Cs[9:8]–Ss[5:0]
0004h	1	Partition type	01h: FAT12 04h, 06h, 0Eh: FAT16 0Bh, 0Ch, 0Fh: FAT32
0005h	16	Partition end head	He
0006h	2	Partition end cylinder and sector	Ce[7:0]–Ce[9:8]–Se[5:0]
0008h	4	First sector position relative to the beginning of media	LBA _s = Cs.H.S+ Hs.S+ Ss–1
000Ch	4	Number of sectors in partition	LBA _e = Ce.H.S+ He.S+ Se–1 Nb s = LBA _e –LBA _s + 1

SD/MMC booting consists of the following steps:

Step 1. MBR detection:

The ROM code checks whether the MBR signature is present and then it searches an active FAT12/16/32 partition in all four MBR partition entries, based on the type field. If the MBR entries are not valid or if no usable partition is found, the ROM code returns to the booting procedure with FAIL. The extended partitions are not checked; the booting file must reside in a primary partition. Each partition entry is checked:

- (a) If its type is set to 00h, all fields in the entry must be 00h.
- (b) The partition is checked to be within physical boundaries (that is, the partition is inside and it fits the total physical sectors).

[Figure 26-27](#) shows the MBR detection procedure.

Figure 26-27. MBR Detection Procedure

init-028

Step 2. Get the MBR partition:

Once identified, the ROM code gets the partition using the procedure described in Figure 26-27. The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h (inactive) or 80h (active.) The ROM code returns with FAIL if no active primary FAT12/16/32 is found, or if there is more than one active partition, the test fails. If an active partition is found, its first sector is read and used later. If no MBR is present (in case of a floppy-like system), the first sector of the booting device is read and used later. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, if another partition type is used (for instance, Linux FS) or if the partition is not valid, the ROM code returns with FAIL.

The FAT file system consists of:

- Boot sector, which holds the BIOS parameter block (BPB). Not all are used by the ROM code.
 - FAT, which describes the use of each cluster of the partition
 - Data area, which holds the files, directories, and root directory (for FAT12/16, the root directory has a specific fixed location)

To check whether a sector holds a valid FAT12/16/32 partition, many fields of the boot sector (used by all FAT types) that must have specific values are checked. Figure 26-28 shows the process to get the MBR partition.

Figure 26-28. Get MBR Partition

init-029

Step 3. Find the booting file:

When a partition is found, the root directory entries are searched for a booting file named MLO in the root directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the root directory has a fixed location, which is cluster 0. For a FAT32 file system, its cluster location is given by BPB_RootClus. The formula to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by:

$$\text{Cluster}_{\text{sector}} = \text{BPB_HiddSec} + \text{BPB_RsvdSecCnt} + \text{BPB_NumFATs} \cdot \text{BPB_FATSz} + \text{Cluster} \cdot \text{BPB_SecPerCLus}$$

init-E001

NOTE: For FAT12/16, BPB_FatSz is BPB_FatSz16.

For FAT32, BPB_FatSz is BPB_FatSz32.

NOTE: The BPB_HiddSec field can contain 0 even though the FAT file system is somewhere other than on sector 0 (floppy-like). The ROM code uses the partition offset taken from the MBR instead of this field, which can be wrong. If no MBR is found (floppy-like), the value 0 is used.

Each entry in the root directory is 32 bytes and holds information about the file (the filename, date of creation, rights, cluster location, etc.). (See [Table 26-39](#).)

Table 26-39. FAT Directory Entry

Offset	Length [Bytes]	Name	Description
0000h	11	DIR_Name	Short Name (8 + 3)
000Bh	1	DIR_Attr	File Attributes: ATTR_READ_ONLY 01h ATTR_HIDDEN 02h ATTR_SYSTEM 04h ATTR_VOLUME_ID 08h ATTR_DIRECTORY 10h ATTR_ARCHIVE 20h ATTR_LONG_NAME ATTR_READ_ONLY ATTR_HIDDEN ATTR_SYSTEM ATTR_VOLUME_ID
000Ch	1	DIR_NTRes	Reserved. Set to 00h.
000Dh	1	DIR_CrtTimeTenth	Millisecond stamp at file creation
000Eh	2	DIR_CrtTime	Time file was created.
0010h	2	DIR_CrtDate	Date file was created.
0012h	2	DIR_LstAccDate	Last access date
0014h	2	DIR_FstClusHi	High word of the first cluster number of this entry
0016h	2	DIR_WrtTime	Time of last write
0018h	2	DIR_WrtDate	Date of last write
001Ah	2	DIR_FstClusLo	Low word of the first cluster number of this entry
001Ch	4	DIR_FileSize	File size in bytes

The ROM code checks each entry in the root directory until either the booting file is found or the entry is empty (first byte is 00h), or when the end of the root directory is reached. Entries with the ATTR_LONG_NAME attribute (LFN) and first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR_FstClusHi/DIR_FstClusLo fields. There is a slight difference between FAT12/16 and FAT32 when handling the root directory. On FAT12/16, this directory has a fixed location (see above) and length fixed by BPB_RootEntCnt, which is the total of 32-byte entries. Handling this directory is therefore straightforward. On FAT32, the root directory is like a standard file. The FAT must be used to retrieve each sector of the directory. The way in which the FAT is handled is described in the following paragraph.

Step 4. Buffer FAT entries in the FAT buffer.

When the booting file is found, the ROM code reads the FAT and buffers the singly-linked chain of clusters in a FAT buffer used by booting to access the file directly, sector by sector. For FAT12/16 and for FAT32, multiple copies of the FAT exist (ROM code supports only two copies), after the boot sector.

$$FATn_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BPB_FatSz \cdot n$$

init-E002

The size of the FAT buffer is given by BPB_FATSz16 or BPB_FATSz32. The ROM code checks each copy of the FAT if they are identical. If the values are different, the ROM code uses the value from the last FAT copy. With the FAT32 file system, the copy system can be disabled according to a flag in BPB_ExtFlags[7]. If this flag is set, the FAT BPB_ExtFlags[3:0] bit field is used. In this case no verification is made by the ROM code with other copies of FAT.

The FAT is a simple array of values, each referring to a cluster located in the data area. One entry of

the array is 12, 16, or 32 bits, depending on the file system in use. The value in an entry defines whether the cluster is being used or not, and if another cluster must be considered. This creates a singly-linked chain of clusters defining the file. The meaning of an entry is described in [Table 26-40](#).

NOTE: For compatibility, cluster 0 and cluster 1 are not used for files, and those entries must contain FF8h and FFFh (for FAT12), FFF8h and FFFFh (for FAT16), and 0FFFFFF8h and 0FFFFFFFh (for FAT32).

Table 26-40. FAT Entry Description

FAT12	FAT16	FAT32	Description
000h	0000h	0000000h	Free cluster
001h	0001h	00000001h	Reserved cluster
002h-FEFh	0002h- FFEFh	00000002h- 0FFFFFFEh	Used cluster; value points to next cluster
FF0h-FF6h	FFF0h- FFF6h	0FFFFFF0h- 0FFFFFF6h	Reserved values
FF7h	FFF7h	0FFFFFF7h	Bad cluster
FF8h-FFFh	FFF8h- FFFh	0FFFFFF8h- 0FFFFFFFh	Last cluster in file

NOTE: FAT32 uses only 28 bits [27:0] of the 32 possible; the upper 4 bits are usually 0 and must be left untouched.

When accessing the root directory for FAT32, the ROM code starts from the root directory cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors, depending on how many sectors are in a cluster (BPB_SecPerClus). This buffer is used later by the booting procedure to access the file.

26.4.7.7 DiskOnChip

The ROM code support for DiskOnChip devices has the following characteristics:

- DiskOnChip H3
- 1.8-V power supply
- Density from 256MB

The DiskOnChip contains an XIP part that can hold a boot image. In this case, the DiskOnChip is connected just like a regular NOR device, and uses the same procedure as for NOR, described in [Section 26.4.7.3, XIP Memory](#).

If booting determines that it must boot from DOC, the ROM code initializes the GPMC using standard asynchronous, 16-bit, multiplexed mode. The DOC device is then detected using the M-System driver. This proprietary driver handles all DiskOnChip protocols and identification. If the booting device cannot be identified, the ROM code returns a failed code. Otherwise, booting directly requests sectors from the M-System driver.

26.4.8 Image Format

26.4.8.1 Overview

An image has two major parts:

- An optional CH
- Software to execute

The CH, which is optional, can contain several parameters set by users to speed up booting. It is further described in the next section.

The mandatory part contains software that is loaded into the memory and executed.

An overview of the image formats is shown in [Figure 26-29](#). There are two image types:

- GP non-XIP memory booting: This image type is used for memories that require shadowing. The image must begin with a simple header that contains information about the size to copy and the destination. This format is described in [Section 26.4.8.3, Image Format for GP Devices](#).
- GP XIP memory booting and peripheral booting: A GP image on XIP memory contains only code. The first sector can contain CH. The GP peripheral booting image contains only code.

Figure 26-29. Image Format

init-018

26.4.8.2 Configuration Header

The CH is optional and is required only if the customer wants to use settings different from the ROM code defaults (for example, clock frequencies, SDRAM/double-data rate [DDR] SDRAM settings, GPMC settings). The CH can be present only when booting from a memory-type device (for example, CH is not supported when booting from UART or USB). Therefore, the CH contains settings only for memory booting.

The CH can contain up to four parts:

- Settings: Clock settings (mandatory)
- RAM: SDRAM/DDR SDRAM interface settings
- FLASH: Flash interface (GPMC) settings
- MMC/SD: MMC/SDIO interface settings

The beginning of the CH is a table of contents (TOC) pointing to each item (see [Figure 26-30](#)). Each TOC item is a simple structure described in [Table 26-41](#). The complete CH (CH TOC and items) must fit in a 512-byte sector.

The ROM code identifies the presence of a CH by reading the first TOC item if it contains a known string (CHSETTINGS, CHRAM, etc.). Then, the TOC is identified and searched until a 0xFFFFFFFF offset is found. The CH is read and parameters are executed sequentially.

Figure 26-30. CH Format

init-019

Table 26-41. CH TOC Item

Offset	Field	Size (Bytes)	Description
0x0000	Start	4	Offset from the start address of TOC to the actual address of a section
0x0004	Size	4	Size of a section
0x0008	Reserved	4	Unused
0x000C	Reserved	4	Unused
0x0010	Reserved	4	Unused
0x0014	Filename	12	12-character name of a section, including the zero (\0) terminator

26.4.8.2.1 CHSETTINGS

The CHSETTINGS configuration header contains settings specific to the clock system. The ROM code configures the device clocking to some default settings as described in [Section 26.4.4.2, Clocking Configuration](#). The CH CHSETTINGS section contains a method to override the ROM code default clocking settings.

The fields are described in [Table 26-42](#). The clocking procedure, as well as the clocking setting structure are described in [Section 26.4.4.4, Software Booting Configuration](#).

The peripherals used during booting, that is, UART and USB are fed with 96 MHz and 48 MHz. This cannot be changed in the configuration header as it is only available for memory booting.

Table 26-42. CHSETTINGS

Offset	Field	Description
0000h	Section key	Key used for section verification: C0C0C0C1h
0004h	Valid	Enables/disables the section 00h: Disable

Table 26-42. CHSETTINGS (continued)

Offset	Field	Description
		Other: Enable
0005h	Version	Configuration header version 0001h Others: For future use
0006h	Reserved	
0008h	Clocking settings	Described in Table 26-12, Software Booting Configuration Structure , starting from the FLAGS field

26.4.8.2.2 CHRAM

The CHRAM configuration header contains settings specific to SDRAM memory controller (SDRC). The fields are described in [Table 26-43](#). The ROM code does not configure the SDRC by default, as it cannot assume any external SDR/DDR SDRAM type. For more information, see [Section 10.2, SDRC](#), in [Chapter 10, Memory Subsystem](#).

Table 26-43. CHRAM

Offset	Field	Description	
		CH – Used in CH Process	CR – Used in Context Restore

0052h	SDRC_RFRCTRL_1 (MSB)	CH	CR
0054h	Reserved, write 0s for future compatibility		CR
0056h	Reserved, write 0s for future compatibility		CR
		CH	CR
0058h	Flags	[0]: 0: CS0 not configured 1: CS0 configured [1]: 0: CS1 not configured 1: CS1 configured	
005A	Must be 0	CH	CR

26.4.8.2.3 CHFLASH

The CHFLASH configuration header contains settings specific to the GPMC. For more information, see [Section 10.1, GPMC](#), in [Chapter 10, Memory Subsystem](#). [Table 26-44](#) lists the fields. The ROM code configures the GPMC by default to these settings:

- CS0
- Asynchronous mode
- Wait input enabled
- Base address 08000000h

Table 26-44. CHFLASH

Offset	Field	Description
0000h	Section key	Key used for section verification: C0C0C0C3h
0004h	Valid	Enables/disables the section: 00h: Disable Others: Enable
0005h	Reserved	
0008h	GPMC_SYSCONFIG (LSB)	Register value
000Ah	GPMC_IRQENABLE (LSB)	
000Ch	GPMC_TIMEOUT_CONTROL (LSB)	
000Eh	GPMC_CONFIG (LSB)	
0010h	GPMC_CONFIG1_0	
0014h	GPMC_CONFIG2_0	
0018h	GPMC_CONFIG3_0	
001Ch	GPMC_CONFIG4_0	
0020h	GPMC_CONFIG5_0	
0024h	GPMC_CONFIG6_0	
0028h	GPMC_CONFIG7_0	
002Ch	GPMC_PREFETCH_CONFIG1	
0030h	GPMC_PREFETCH_CONFIG2 (LSB)	
0032h	GPMC_PREFETCH_CONTROL (LSB)	
0034h	GPMC_ECC_CONFIG	
0036h	GPMC_ECC_CONTROL	
0038h	GPMC_ECC_SIZE_CONFIG (LSB)	
003Ch	Enable_A1_A10	0: Do not change A1– A10 Others: Enable pins A1 – A10

26.4.8.2.4 CHMMCSD

The CHMMCSD configuration header contains settings specific to the high-speed MMC/SD/SDIO host controller (MMCHS). For more information, see [Chapter 24, MMC/SD/SDIO Card Interface](#). **Table 26-45** lists the fields. The ROM code configures the MMCHS by default to these settings:

- 400-kHz clock during identification mode
- 19.2-MHz clock during data transfer mode

Table 26-45. CHMMCSD CH

Offset	Register Modified	Description
0000h	Section key	Key used for section verification C0C0C0C4h
0004h	Valid	Enables/disables the section 00h: Disable Other: Enable
0005h	Reserved	
0008h	MMCHS_SYSCTRL(MSB)	Register value
000Ah	MMCHS_SYSCTRL(LSB)	0xFFFFFFFF -> Do not update register.
000Ch	Bus width	1 -> 1 bit 2 -> 4 bits 4 -> 8 bits (on SD/MMC2 interface only) 0xFFFFFFFF -> Do not update register.

NOTE: The ROM code transmits a booting parameter structure to the initial software (see [Section 26.4.8.4, Image Execution](#)). This structure contains a field that indicates whether the configuration header sections have been correctly considered. For the CHMMCSD section, if all the section fields are set to 0xFFFFFFFF, regardless of the value of the VALID bit field, the booting parameters should indicate that the CHMMCSD section has not been executed.

26.4.8.3 Image Format for GP Devices

For a GP device, the image is simple and must contain a small header having the size of the software to load and the destination address of where to store it when a booting device is other than XIP. The XIP device image is even simpler and starts with executable code. [Table 26-46](#) describes the image format. The header is used only for memory booting. The peripheral booting image does not have a header and starts directly with executable code.

Table 26-46. GP Device Software Image

Field	Non-XIP Device	XIP Device	Size (Bytes)	Description
	Offset	Offset		
Size	0x0000	—	4	Size of the image
Destination	0x0004	—	4	Address where to store the image
Image	0x0008	0x0000	x	Image

26.4.8.4 Image Execution

The image is executed when the ROM code performs a branch instruction to the first executable instruction in the initial software. The execution address is the first word after the image header. After the branch, the ARM® runs in public ARM supervisor mode. The R0 register points to the booting parameter structure that contains information about booting. [Table 26-47](#) shows the booting parameters structure.

Table 26-47. Booting Parameter Structure

Offset	Field	Size (Bytes)	Description
0x00	Boot message	4	Last received booting message
0x04	Current booting device	1	Code of booting device used for booting: 0x01: XIP memory 0x02: NAND 0x03: OneNAND 0x04: DOC 0x05: MMC/SD2 0x06: MMC/SD1 0x07: XIP memory with wait monitoring 0x08: MMC/SD2 with hybrid connection 0x10: UART 0x11: HS USB Other: Reserved
0x05	Reserved	1	Reserved

Table 26-47. Booting Parameter Structure (continued)

Offset	Field	Size (Bytes)	Description
0x06	Reset reason	1	Current reset reason bit mask (bit = 1, event present): [0]: Power-on reset (POR) [1]: Global software reset [2]: Reserved [3]: Reserved [4]: WDT2 reset [5]: Reserved [6]: External warm reset [7]: VDD1 voltage manager reset [8]: VDD2 voltage manager reset [9]: ICEPick™ reset [10]: ICECrusher™ reset Other bits: Reserved
0x07	CH flags	1	Configuration header sections flag. Each section is described by 1 bit. A set bit indicates that the section was executed: [0]: CHSETTINGS [1]: CHRAM [2]: CHFLASH [3]: CHMMC Other bits: Reserved
0x08	Device descriptor	4	Pointer to the device descriptor structure. This pointer is required when current booting device driver functions are called.

26.4.9 Tracing

Tracing in the public ROM code consists of a 64-bit vector in which each bit corresponds to a certain point of the ROM code execution flow. The tracing vector is divided into two 32-bit words. [Table 26-48](#) lists the location and organization of the tracing data in RAM. Tracing data is initialized at the beginning of startup.

There are two sets of tracing data: current trace information and tracing collected during the first ROM code run after a cold reset. This cold reset tracing is copied to its location during the tracing initialization of the second ROM code run after the cold reset run. These data can be used for debugging.

Table 26-48. Tracing Vector

Bit Number	Group	Meaning
0	General	Reset
1	General	ROM code C main
2	General	ROM code runs after the cold reset
3	Boot	Booting started
4	Memory boot	Memory booting started
5	Boot	No more booting device to check
6	Peripheral boot	Peripheral booting started
7	Boot	Booting message change booting device
8	Boot	Booting message skip per. booting
9	Reserved	Reserved
10	Memory boot	CH found
11	Memory boot	Image header correct
12	Peripheral boot	Device initialized
13	Peripheral boot	ASIC-ID sent

Table 26-48. Tracing Vector (continued)

Bit Number	Group	Meaning
14	Peripheral boot	Booting message received
15	Peripheral boot	Image received
16	Peripheral boot	Peripheral booting failed
17	Peripheral boot	UART
18	Peripheral boot	USB
19	Reserved	Reserved
20	Reserved	Reserved
21	Peripheral boot	NULL device
22	Execute	Image executed
23	Reserved	Reserved for non-GP devices
24	Reserved	Reserved for non-GP devices
25	Reserved	Reserved for non-GP devices
26	Reserved	Reserved for non-GP devices
27	Reserved	Reserved for non-GP devices
28	Reserved	Reserved for non-GP devices
29	Boot	Software booting configuration section 1 found
30	General	Software booting configuration clocking section found
31	Reserved	Reserved
32	Memory boot	Null device
33	Memory boot	XIP

44	Reserved	Reserved
45	Reserved	Reserved
46	Reserved	Reserved
47	Memory boot	No known NAND was detected.
48	Memory boot	MLC NAND image was detected.
49	Memory boot	NAND boot was attempted from block 0.
50	Memory boot	NAND boot was attempted from block 1.
51	Memory boot	NAND boot was attempted from block 2.
52	Memory boot	NAND boot was attempted from block 3.

26.5 Wake-Up Booting by ROM Code

In CORE OFF power state, all configurations outside the WKUP power domain are reset and must be restored to restart the system in the condition it was in before being stopped. After an MPU and CORE power domain wake-up reset, the ROM code restores the SDRC and clock settings to allow a jump to a public restore function. This public restore function is specifically implemented by users to restore their own hardware and software environments. Users must set the public restore function address in the public restore pointer field of the CONTROL_SAVE_RESTORE_MEM structure.

The CONTROL_SAVE_RESTORE_MEM memory of the SCM saves and restores mandatory information to automatically reconfigure the SDRC and PRCM registers. The SDRC and clock registers must be saved by users in the respective structures (see [Table 26-50](#) and [Table 26-51](#)) in the SCM (scratchpad memory) before going to off mode to be automatically restored on wake-up boot by the ROM code.

The size of CONTROL_SAVE_RESTORE_MEM is 240 bytes starting at the hardware physical address 0x48002910 to 0x480029FF. [Figure 26-31](#) shows the memory format that must be obeyed to handle the context restoration.

Figure 26-31. CONTROL_SAVE_RESTORE_MEM Format

init-021

Table 26-49. CONTROL_SAVE_RESTORE_MEM Field Definitions

Field Name	Size	Description
Booting Configuration Pointer	32 bits	Address of public booting information used after a software reset
Public Restore Pointer ⁽¹⁾	32 bits	Address of the public restore function to branch to when exiting a wake-up reset boot

⁽¹⁾ Field to be set by users

Table 26-49. CONTROL_SAVE_RESTORE_MEM Field Definitions (continued)

Field Name	Size	Description
SDRC Module Semaphore ⁽²⁾	32 bits	Semaphore used for accessing the SDRC module
PRCM Block Offset ⁽¹⁾	32 bits	Offset of the PRCM configuration in the control save restore memory. Set 0x0 to not use this block. When the block is used the minimum allowed value is 0x18.
SDRC Block Offset ⁽¹⁾	32 bits	Offset of the SDRC configuration in the control save restore memory. Set 0x0 to not use this block. When the block is used the minimum allowed value is 0x18.

⁽²⁾ ROM code use only

26.6 Debug Configuration

26.6.1 Overview

This section provides information for using a debugger on the public ARM Cortex™-A8 in the device. The debug capability is accessible through the JTAG interface with a limited number of pins.

26.6.2 JTAG Port Signal Description

The target debug interface of the device uses the five standard IEEE 1149.1 (JTAG) signals (nTRST, TCK, TMS, TDI, and TDO), a return clock (RTCK) to meet the clocking requirements of the ARM968 processor, and two instrumentations pins (EMU0, EMU1). [Table 26-52](#) lists the debug POR signals.

Table 26-52. Debug POR Signals

Pin	Type ⁽¹⁾	Name	Description
jtag_nrst	I	Test logic reset	When asserted (active low), causes all test and debug logic in the device to be reset with the IEEE 1149.1 interface
jtag_tck	I	Test clock	Test clock used to drive an IEEE 1149.1 test access port (TAP) state-machine and logic. Depending on the emulator attached to the device, this is a free-running clock or a gated clock, depending on RTCK monitoring.
jtag_rtck	O	Returned test clock	Synchronized TCK. Depending on the emulator attached to device, the JTAG signals are clocked from RTCK or RTCK is monitored by the emulator to gate TCK.
jtag_tms	I	Test mode select	Directs the next state of the IEEE 1149.1 TAP state-machine
jtag_tdi	I	Test data input	Scan data input to the device.
jtag_tdo	O	Test data output	Scan data output of the device.
jtag_emu0	I/O	Emulation 0	Channel 0 trigger: Boot mode
jtag_emu1	I/O	Emulation 1	Channel 1 trigger: Boot mode

⁽¹⁾ I = Input; O = Output

To reduce power consumption, the power domain that contains the debug logic can be switched off in normal operating mode.

CAUTION

Before starting the debugger, the DEBUG power domain must be activated by applying a minimum of 10 TCK pulses to the device after nTRST is pulled high. To prevent the JTAG_TMS pin from floating when the EMU power domain is off, an external pullup (10 kΩ) must be added.

26.6.3 Initial Scan Chain Configuration

The GP ports that can provide access to many test support functions built into the device (including the test logic defined by the IEEE 1149.1 standard) are the TAP.

The first level of the debug interface that sees the scan controller is the TAP router module.

The debugger can configure the TAP router to link to 16 TAP controllers serially or to scan one TAP controller individually without disrupting the instruction register (IR) state of the other TAPs. The initial scan chain configuration of the device is determined from the level of the EMU0 and EMU1 pins on the release of POR. At POR, EMU0 and EMU1 are automatically configured as inputs. The EMU0 and EMU1 pins must be pulled high at POR to configure the initial scan chain of the device to the TAP router-only mode. In the TAP router-only configuration, no secondary TAPs are selected. The TAP router is the only TAP between the device-level TDI and TDO.

The router TAP has an IR length of 6 bits. This is the recommended boot mode. The third-party debugger must assume that the TAP router is the only TAP between TDI and TDO at boot.

26.6.4 Adding TAPs to the Scan Chain

The TAP router must be programmed to add TAPs to the scan chain (used in Design For Test). The following JTAG scans must be completed before the CoreSight debug access port (DAP) is added to the scan chain. CoreSight is the on-chip debug and trace ARM technology. IR and DR are the instruction register and the data register, respectively.

```
## Function : Update the JTAG preamble and post-amble counts. Parameter : The IR pre-amble count is '0'. Parameter : The IR post-amble count is '0'. Parameter : The DR pre-amble count is '0'. Parameter : The DR post-amble count is '0'. Parameter : The IR main count is '6'. Parameter : The DR main count is '1'. ## Function : Do a send-only JTAG IR/DR scan. Parameter : The route to JTAG shift state is 'shortest transition'. Parameter : The JTAG shift state is 'shift-ir'. Parameter : The JTAG destination state is 'pause-ir'. Parameter : The bit length of the command is '6'. Parameter : The send data value is '0x00000007'. Parameter : The actual receive data is 'discarded'. ## Function : Do a send-only JTAG IR/DR scan. Parameter : The route to JTAG shift state is 'shortest transition'. Parameter : The JTAG shift state is 'shift-dr'. Parameter : The JTAG destination state is 'pause-dr'. Parameter : The bit length of the command is '8'. Parameter : The send data value is '0x00000089'. Parameter : The actual receive data is 'discarded'. ## Function : Do a send-only JTAG IR/DR scan. Parameter : The route to JTAG shift state is 'shortest transition'. Parameter : The JTAG shift state is 'shift-ir'. Parameter : The JTAG destination state is 'pause-ir'. Parameter : The bit length of the command is '6'. Parameter : The send data value is '0x00000002'. Parameter : The actual receive data is 'discarded'. ## Function : Embed the POR address in next command. Parameter : The POR address field is '0x0f000000'. Parameter : The POR address value is '3'. ## Function : Do a send-only JTAG IR/DR scan. Parameter : The route to JTAG shift state is 'shortest transition'. Parameter : The JTAG shift state is 'shift-dr'. Parameter : The JTAG destination state is 'pause-dr'. Parameter : The bit length of the command is '32'. Parameter : The send data value is '0xa3002108'. Parameter : The actual receive data is 'discarded'. ## Function : Do a send-only all-ones JTAG IR/DR scan. Parameter : The JTAG shift state is 'shift-ir'. Parameter : The JTAG destination state is 'run-test/idle'. Parameter : The bit length of the command is '6'. Parameter : The send data value is 'all-ones'. Parameter : The actual receive data is 'discarded'. ## Function : Wait for a minimum number of TCLK pulses. Parameter : The count of TCLK pulses is '10'. ## Function : Update the JTAG preamble and post-amble counts. Parameter : The IR pre-amble count is '0'. Parameter : The IR post-amble count is '6'. Parameter : The DR pre-amble count is '0'. Parameter : The DR post-amble count is '1'. Parameter : The IR main count is '4'. Parameter : The DR main count is '1'.
```

After the DAP is added to the scan chain, the debugger can communicate with the Cortex-A8 processor.

26.6.5 Debugger Address Space

The CoreSight components are interfaced with the TAP router through the DAP. As recommended by the CoreSight architecture, the DAP is directly interfaced to the device bus. The debugger can directly access the entire memory space without requiring the processor to enter debug state and be programmed with a load or store instruction. [Table 26-53](#) lists the modules that are mapped to the DAP address, and the address space detail.

Table 26-53. Debugger Address Space

Start Addr (Hex)	End Addr (Hex)	Size	Description
0x5401 0000	0x5401 0FFF	4KB	ARM embedded trace macrocell (ETM) module
0x5401 1000	0x5401 1FFF	4KB	Cortex-A8 module
0x5401 9000	0x5401 9FFF	4KB	Trace port interface unit (TPIU)
0x5401 B000	0x5401 BFFF	4KB	ARM embedded trace buffer (ETB) module

The DBGEM signal on the Cortex-A8 is driven by setting bit 13 at address 0x5401 D030 in the DAP-APB address space.

Debug and Emulation

This chapter describes the debug and emulation module on the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page

27.1 Debug and Emulation Overview

This chapter presents an overview of the debug and emulation hardware features.

27.1.1 Debug and Emulation Overview Features

Debugging a system containing multiple embedded processors involves an environment that connects high-level debugging software, executing on a host computer, to a low-level debug interface supported by the device. Between these levels is an emulator, which facilitates communication between the host debugger and the emulation logic on the device.

Debug and emulation is a combination of hardware and software that connects the host debugger to the target device. It uses one or more hardware interfaces and/or protocols to convert actions dictated by the debugger user to JTAG commands and scans that execute the core hardware.

[Figure 27-1](#) shows the module used in the device for debug and emulation.

Figure 27-1. Debug and Emulation Hardware in the Device

The debug software and hardware components lets the user control multiple central processing unit (CPU) cores embedded in the device in a global or local manner. This environment provides:

- Synchronized global starting and stopping of multiple processors (the ICEPick™ feature is not supported by all the platform processors)
- Starting and stopping of an individual processor
- Each processor can generate triggers that can be used to alter the execution flow of other processors.

27.1.2 Debug and Emulation Functional Description

27.1.2.1 ICEPick

The device contains multiple processors, each of which has a JTAG test access port (TAP) embedded in the processor. The ICEPick module manages these TAPs and the power, clock, and reset controls for the module that has the TAP. At its root, ICEPick is a scan path linker that allows the scan controller to selectively choose which subsystem TAPs are accessible through the device level debug port. ICEPick is configured through its IEEE 1149.1 JTAG TAP controller.

The ICEPick module is described in [Section 27.2, ICEPick Module](#).

27.1.2.2 SDTI

The system debug trace interface (SDTI) is a component that implements the device system trace. The SDTI module provides real-time software tracing functionality to the device. It generates operating system monitor messages that are encoded as defined in the custom protocol.

NOTE: The custom protocol is not MIPI® compliant.

Messages let software provide crucial information, thus providing a high level of visibility on system behavior (task entry, procedures calls, system status, test signatures, and memory allocation); 256 message channels, which can be allocated between software components, are available.

The SDTI implements only trace export from the device to a remote PC through an emulator box. There is no receive path feature in the SDTI. A standard asynchronous serial port (universal asynchronous receiver/transmitter [UART], 8 data bits, 1 stop-bit, no parity) can be used as a back-channel to send emulation-related control requests and data back to the device.

The SDTI is described in [Section 27.3, SDTI Module](#).

27.1.2.3 EPM

The emulation pin manager (EPM) manages emulation pin multiplexing to the application pin manager. It allows the selection of an emulation interface to be routed to the device boundary pads.

The EPM is described [Section 27.4, Emulation Pin Manager](#).

27.1.2.4 DAP

The debug access port (DAP) enables the external debugger to directly access the entire memory space of the device without requiring the processor to enter the debug state and be programmed with a load or store instruction.

The DAP directly interfaces with the device level 4 (L4) EMU interconnect. The DAP is attached to the last ICEPick secondary TAP and translates JTAG transactions into interconnect transactions.

For more information about the DAP, see the documentation section at <http://www.arm.com/>.

27.1.2.5 ETM

The embedded trace macrocell (ETM) generates a real-time trace to the trace port interface unit (TPIU) or is stored in the embedded trace buffer (ETB).

For more information about the ETM, see the documentation section at <http://www.arm.com/>.

27.1.2.6 ETB

The ETB stores the trace generated by the ETM. The trace can then be read by the JTAG interface.

For more information about the ETB, see the documentation section at <http://www.arm.com/>.

27.1.2.7 TPIU

The TPIU is used to export the ETM trace at the device pads.

For more information about the TPIU, see the documentation section at <http://www.arm.com/>.

27.2 ICEPick Module

This section describes the ICEPick module in the device.

27.2.1 ICEPick Overview

System-on-a-chip designs typically have multiple processors, each of which has a JTAG TAP embedded in the processor. The ICEPick module manages these TAPs and the power, clock, and reset controls for modules that have TAPs. At its root, ICEPick is a scan path linker that lets the scan controller selectively choose which subsystem TAPs are accessible through the device level debug port. ICEPick is configured through its IEEE 1149.1 JTAG TAP controller. [Figure 27-2](#) is an overview of the ICEPick module in the device.

Figure 27-2. ICEPick Overview

ICEPick supports:

- Individually selecting one or more of the TAPs for scan without disrupting the state of other TAPs
- Management of the reset to many processors
- Management of the power and clock of many power domains

The ICEPick module has the following characteristics:

- IR length of 6 bits
- DR length of 1 in bypass mode
- DR length from 1 to 32 (see [Section 27.2.4.5, ICEPick Instructions](#))
- Boot mode controlled by device pins (see [Section 27.2.2, ICEPick Environment](#))

27.2.2 ICEPick Environment

The ICEPick module is connected to the JTAG interface in the device. The JTAG interface has six pins plus two pins for selecting ICEPick boot mode (see [Table 27-1](#)).

Table 27-1. JTAG Pins

PAD	Name	Width	Type ⁽¹⁾	Reset Value	Description
jtag_nrst	Test Logic Reset	1	I	HiZ	When asserted (active low), causes all test and debug logic in the device to be reset along with the IEEE 1149.1 interface.

⁽¹⁾ I = Input; O = Output

Table 27-1. JTAG Pins (continued)

PAD	Name	Width	Type ([†])	Reset Value	Description
jtag_tck	Test Clock	1	I	HiZ	This is the test clock used to drive an IEEE 1149.1 TAP state-machine and logic. Depending on the emulator attached to the device, this is a free-running clock or a gated clock, depending on RTCK monitoring.
jtag_rtck	Returned Test Clock	1	O	0	Synchronized TCK. Depending on the emulator attached to the device, the JTAG signals are clocked from RTCK or RTCK is monitored by the emulator to gate TCK.
jtag_tms	Test Mode Select	1	I	HiZ	Directs the next state of the IEEE 1149.1 TAP state-machine
jtag_tdi	Test Data Input	1	I	HiZ	Scans data input to the device
jtag_tdo	Test Data Output	1	O	HiZ	Scans data output of the device
jtag_emu0	Emulation 0	1	IO	HiZ	Channel 0 trigger – boot mode – HS-RTDX – trace port
jtag_emu1	Emulation 1	1	IO	HiZ	Channel 1 trigger – boot mode – HS-RTDX – trace port

For more information about ICEPick boot modes, see [Section 27.2.4.4](#).

The ICEPick module has a TAP state-machine consistent with the IEEE 1149.1 specification. For more information about TAP states, see [Section 27.2.4.3](#).

27.2.3 ICEPick Integration

The ICEPick module is in the EMU power domain.

The ICEPick module use only JTAG clocks (jtag_tck and jtag_rtck). These clocks are external clocks and are not managed by the device power, reset, and clock management (PRCM) module.

27.2.4 ICEPick Functional Description

27.2.4.1 ICEPick Block Diagram

[Figure 27-3](#) is the block diagram of the ICEPick module with the four external (secondary) TAPs connected to the ICEPick scan chain.

Figure 27-3. ICEPick Overview

icepick-006

27.2.4.2 ICEPick Secondary Debug TAPs

[Table 27-2](#) shows the secondary debug TAPs connected to the ICEPick scan chain. The TAP number shows the position of the TAP in the scan chain and the SDTRj register (see [Table 27-23](#)) used to get access to control and status for this TAP. The ICEPick internal TAP can also be referenced as the primary TAP; it is always in the first position in the scan chain (ICEPick TAP input is connected to the device jtag_tdi pin).

Table 27-2. Secondary Debug TAP Mapping

Secondary JTAG port	CoreSight	TAP No.	Modules Accessed Through That JTAG Port
D2D	No	0	Die-to-die interface
IVA	No	1	C64x+/ICEMaker
ARM968™	No	2	ARM968/ICECrusher™ – IVA Sequencer
DAP	Yes	3	MPU/ICECrusher – CS / ETM11 / PSA
	Yes		ETB
	Yes		SDTI
	No		Clocks Management → L3 → L4_CORE
	No		Power Management → L4_EMU → L4_WKUP
Reserved	No	4–15	Reserved

27.2.4.3 ICEPick TAP states

The TAP consists of:

- 32-bit device ID register
- 1-bit bypass register
- 6-bit instruction register (IR)

[Figure 27-4](#) shows ICEPick TAP states. In the figure, TMS corresponds to the jtag_tms input pin.

Figure 27-4. TAP State Transitions

icepick-004

27.2.4.4 ICEPick Boot Modes

The initial configuration of ICEPick is determined from the level of jtag_emu0 and jtag_emu1 at POR release. At POR, jtag_emu0 and jtag_emu1 are automatically configured as inputs.

In ICEPick-only configuration, none of the secondary TAPs are selected. The ICEPick TAP is the only TAP between the device level TDI and TDO. This is the recommended boot mode (jtag_emu0 and jtag_emu1 are set at 1).

The device can boot to invoke wait-in-reset mode. This mode keeps the device microprocessor unit (MPU) in wait-in-reset mode until the ICEPick module disables the MPU reset through a JTAG by writing the SDTRj register (see [Table 27-23](#)).

When TCK direct boot mode is used, the ICEPick clock voting logic is bypassed. TCK is driven onto each secondary TAP.

[Table 27-3](#) shows the values of jtag_emu0 and jtag_emu1 used to select different boot modes.

Table 27-3. ICEPick Boot Mode

jtag_emu1	jtag_emu0	TAPs in the TDI → TDO Path	Other Effects
0	0	ICEPick + D2D	Boundary scan stacked die
0	1	ICEPick	TCK direct
1	0	ICEPick	Wait-in-reset
1	1	ICEPick	

27.2.4.5 ICEPick Instructions

27.2.4.5.1 ICEPick Instruction List

ICEPick TAP supports the instructions listed in [Table 27-4](#). All unused TAP controller instructions default to the bypass register. Several instructions are reserved for extensions to the ICEPick opcodes.

Table 27-4. ICEPick Instructions

IR	ICEPick Instruction	Extended Instruction	Access
000000	BYPASS	Not available	Always-open
000001	Reserved	Not available	Always-open

111111	BYPASS	BYPASS	Always-open

27.2.4.5.2 Instruction Register Scan Path and State

Capture IR state: The binary value 000001b is loaded into the data shift register.

Shift IR state: The IR shift section of the data shift register is selected as the serial path between the ICEPick TDI and TDO. The value captured at Capture IR is shifted out during Shift IR, with the least significant bit (LSB) first, while a new instruction is shifted in, also with the LSB first.

Update IR state: The value in the data shift register is loaded into the instruction register so it becomes the current instruction.

Test Logic Reset state: On TAP reset, the IDCODE becomes the current instruction. When the ICEPick TAP reaches the Test Logic Reset state, the IR register is automatically loaded with the IDCODE instruction.

27.2.4.5.3 Data Shift Register Scan Path and State

27.2.4.5.3.1 IDCODE Instruction

Description: The IDCODE instruction specifies that the DR shift path is 32 bits long. This path provides a way to export the value of the identification (ID) register in the device. The ID register is a 32-bit register that specifies the manufacturer, part number, and version of the component (see [Table 27-10](#)). The use of this instruction has no effect on the operation of the on-chip system logic.

Capture DR state: The 32-bit ID code of the device is loaded into the data shift register during the Capture DR state.

Shift DR state: The value captured is shifted out during the Shift DR TAP state with the LSB first, while the value of jtag_tdi is shifted into the most-significant bit (MSB) of the data shift register. Data is shifted from the MSB to the LSB.

Update DR state: The shifted-in data is ignored in the Update DR state.

The device ID can be determined following the generation of the Test Logic Reset TAP state. The Test Logic Reset TAP state causes all JTAG-compliant devices to load the IR with an IDCODE or a BYPASS instruction. These two opcodes provide a different first output (1 for IDCODE; 0 for BYPASS) during the first Shift DR state after the TRST, provided the DR Scan occurs without an intervening IR scan.

Therefore, examination of the first bit of data that is shifted out of a component during a test data scan sequence immediately after exiting the Test Logic Reset state shows whether a device ID register is included in the design.

When test data register scanning is entered in this way, the serial path at the board level includes:

- The device ID registers of components that provide them
- The bypass registers of components that do not include a device ID register

Examination of the first bit of data shifted out of a component as a result of the above interrogation sequence identifies the data as coming from the bypass bit or a device ID register. ICEPick exports a device ID for this sequence, thus providing a way to retrieve and identify the device ID.

27.2.4.5.3.2 ICEPICKCODE Instruction

Description: The ICEPICKCODE instruction specifies that the DR shift path is 32 bits long. This path provides a way to export the ICEPick identification (IPID) register (see [Table 27-12](#)). The IPID register is a 32-bit register that specifies the features and version of ICEPick. This ID register is for the ICEPick module and should not be confused with the ID register for the device or any other module. The use of this instruction has no effect on the operation of the on-chip system logic.

Capture DR state: The 32-bit ICEPick code is loaded into the data shift register during the Capture DR state.

Shift DR state: The value captured is shifted out during the Shift DR TAP state with the LSB first, while the value of `jtag_tdi` is shifted into the MSB of the data shift register. Data is shifted from the MSB to the LSB.

Update DR state: The shifted-in data is ignored in the Update DR state.

27.2.4.5.3.3 USERCODE Instruction

Description: The USERCODE instruction specifies that the DR shift path is 32 bits long. This path provides a way to export the value of the user code (UC) register (see [Table 27-11](#)). The UC register is a 32-bit register that specifies the variant of a device. The use of this instruction has no effect on the operation of the on-chip system logic.

Capture DR state: The 32-bit UC register in the device is loaded into the data shift register during the Capture DR state.

Shift DR state: The value captured is shifted out during Shift DR TAP state with the LSB first, while the value of `jtag_tdi` is shifted into the MSB of the data shift register. Data is shifted from the MSB to the LSB.

Update DR state: The shifted-in data is ignored in the Update DR state.

27.2.4.5.3.4 BYPASS Instruction

Description: The IEEE 1149.1 specification mandates a BYPASS instruction and that the instruction decode must be an all-ones value equal in length to the instruction register length. All unused TAP controller instruction codes default to having the same characteristics as the BYPASS instruction.

The BYPASS instruction, and all instruction codes defaulting to the BYPASS instruction, specifies a DR shift path 1 bit long between the ICEPick TDI and TDO. This path provides a way to export the 0 used to differentiate bypass data from the data in the device ID register, if a DR scan is performed immediately following the Test Logic Reset TAP state.

Capture DR state: In the Capture DR state, 0 is loaded into the 1-bit shift path selected by this instruction.

Shift DR state: When the BYPASS instruction is the current instruction in the instruction register, serial data is transferred from TDI to TDO through the 1-bit bypass register while in the Shift DR state with a delay of one TCK cycle.

Update DR state: The shifted-in data is ignored in the Update DR state.

The BYPASS instruction is used when a scan controller wants to shift in data or commands to another TAP on the scan path without disturbing this TAP.

27.2.4.5.3.5 CONNECT_PUBLIC Instruction

Description: The CONNECT_PUBLIC instruction, in combination with the connect register, is used to enable many of the other IR instructions. Before being enabled, the instructions act as the BYPASS instruction.

The CONNECT_PUBLIC instruction specifies that the DR shift path is 8 bits long. This path provides a way to access the connect register, which is described in [Table 27-13](#).

Capture DR state: When the CONNECT instruction is in the IR, a DR scan scans through the 8 lower bits of the data shift register. Bit 7 is not part of the connect register (0 is used to read the register; 1 is used to write the register).

Shift DR state: When in the Shift IR state, the connect shift section of data shift register is selected as the serial path between the ICEPick TDI and TDO. The value captured at Capture DR is shifted out to ICEPick TAP TDO during Shift DR, with the LSB first. The value on jtag_tdi is shifted into the data shift register. Data is shifted from the MSB to the LSB.

NOTE: While the value is being scanned out, a new register access (read or write) can be scanned in.

Update DR state: On read and write, the scan chain is decoded at the Update DR state. The value of bit 7 determines whether the connect register is written at the Update DR state. If 1, the register is written.

27.2.4.5.3.6 CONNECT_PRIVATE

Description: The CONNECT_PRIVATE instruction, in combination with the private enable register, is used to enable extended TAP functions. The CONNECT_PRIVATE instruction is accessible only after the Connect Public scan sequence is complete.

The CONNECT_PRIVATE instruction specifies that the DR shift path is 1 bit in length. This path provides a way to access the private enable register.

Capture DR state: In the Capture DR state, the current value of Private_Enable is loaded into the 1-bit shift path selected by this instruction.

Shift DR state: When the CONNECT_PRIVATE instruction is the current instruction in the instruction register, serial data is transferred from TDI to TDO through the 1-bit Private_Enable register while in the Shift DR state with a delay of one TCK cycle.

Update DR state: The shifted-in data is latched in a temporary register in the Update DR state.

Run Test Idle state The data value in the temporary register is written to Private_Enable when the Run_Test_Idle state is reached.

The Private_Enable instruction is used to prevent extended TAP functions from being invoked until the connect sequence completes. This can be used to ensure test functions are held in reset, even though the chip-level test reset is no longer asserted.

27.2.4.5.3.7 ROUTER Instruction

Description: The ROUTER instruction specifies that the DR shift path is 32 bits long. This path provides a way to access the ICEPick TAP linking, status, and control registers. It provides accessibility to the secondary TAP controls for each TAP that ICEPick manages (see [Section 27.2.4.6.3.1, TAP_ROUTING_REG Description](#)).

The ROUTER instruction connects the ICEPick router scan path between TDI and TDO when doing a DR scan. This scan chain facilitates reading and writing of all ICEPick registers. All ICEPick functions are accessed through registers. The ROUTER instruction is used to read and write the registers.

NOTE: To use the ROUTER instruction, ICEPick must be in the connected state. Otherwise, this instruction acts like the BYPASS instruction.

Capture DR state: During the Capture DR state, the data shift register is inspected. The register specified by the block and register fields is read and the value is placed in the lower 24 bits of the data shift register.

NOTE: The current contents of the data shift register are those loaded by the previous scan. The register specified in DR scan n-1 is read during scan n. If an intervening IR scan occurs, the contents of the data shift register are unpredictable; therefore, a read of the register indicated in DR scan n-1 does not occur.

The write-failure (WF) bit is captured into the data shift register at bit 31. Once the value is captured, the WF flag is cleared.

Shift DR state: The 32-bit value captured is shifted out during the Shift DR TAP state with the LSB first, while the value of jtag_tdi is shifted into the MSB of the data shift register. Data is shifted from the MSB to the LSB.

The shifted-in value may contain a new register read or write request and the associated payload.

Update DR state: For a read or write, the scan chain is decoded during the Update DR state.

Figure 27-5 shows multiple read access in the ROUTER instruction.

Figure 27-5. Multiple Read in ROUTER Instruction

Figure 27-6 shows multiple write access in the ROUTER instruction.

Figure 27-6. Multiple Write in ROUTER Instruction

Figure 27-7 shows mixed read and write access in the ROUTER instruction.

Figure 27-7. Mixed Read and Write in ROUTER Instruction

27.2.4.6 ICEPick Registers

ICEPick registers are accessed through the ICEPick TAP.

27.2.4.6.1 Registers

Table 27-5 shows the ICEPick registers.

Table 27-5. ICEPick Registers

Register	Name	Width	Number	Description
Data shift register	DSR	32	1	TAP data register
Instruction register	IR	6	1	TAP instruction register
Bypass register	BP	1	1	Used by the BYPASS instruction
Device identification register	TAPID	32	1	Device ID used with IDCODE
User code register	UC	32	1	User Code used with USERCODE
ICEPick identification	IPID	32	1	Version of ICEPick
Connect	CONNECT	8	1	Connect code
All 0s	ALL0S	24 ⁽¹⁾	1	Returns 0s
ICEPick control	CONTROL	24 ⁽¹⁾	1	General ICEPick control
Linking mode	LINKING_MODE	24 ⁽¹⁾	1	Specifies how ICEPick manages the TAP selection
Secondary debug TAP register	SDTRj	24 ⁽¹⁾	16	One register exists for each test TAP instantiated. It is used to control selection of each TAP.

⁽¹⁾ Register is 32 bits, but 8 upper bits are used for read/write, block, and register selection. See [Table 27-14](#) pseudo register.

27.2.4.6.2 Register Reset Conditions

Each register bit has a reset condition. One of these reset conditions is used to reset each bit in ICEPick. [Table 27-6](#) shows the reset conditions.

Table 27-6. Register Reset Conditions

Condition	Description
-	The bit always reflects the current value of an input signal.
Fixed	The bit is set to a particular value and does not change during operation.
POR	The bit is reset upon POR.
QTLR	The bit is reset upon state change to Test Logic Reset if the ICEPick TAP is visible and the ICEPick register reset is not blocked. In this sense, reset based on reaching the Test Logic Reset state is qualified.
QnTRST	The bit is reset on assertion low of the device pin nTRST if the ICEPick TAP is visible and the ICEPick register reset is not blocked. In this sense, reset based on nTRST assertion is qualified. Because the assertion of nTRST changes the TAP state to Test Logic Reset, the QTLR reset condition often applies. Unlike QTLR, a bit that is reset based on this condition is not reset if the Test Logic Reset state is reached through changes in TAP state.
ARST	The bit is reset upon any of the above resets. In other words, the bit is reset upon POR or QTLR or QnTRST. In practice, QnTRST is not needed in this equation because nTRST assertion drives the TAP state to Test Logic Reset so the QTLR condition will then apply.

27.2.4.6.3 Register Description

[Table 27-7](#) through [Table 27-13](#) describe the individual registers.

Table 27-7. DSR

Description	The data shift register is the register used to shift bits between the ICEPick TDI and TDO. This register is 32 bits wide. It has multiple shift in points to facilitate shifts on the instruction path and several of the data paths.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																													BYPASS		
RESERVED																									Instruction shift						
RESERVED																									Connection shift						

When asked to shift, one bit is shifted from each bit into the next lower bit. A new value is shifted in from TDI while the LSB is shifted out to TDO. The shift register has several insertion points based upon the current TAP state or value in the instruction register.

Table 27-8. IR

Description	The instruction register (IR) contains the current TAP instruction. ICEPick's instruction register is 6 bits wide
Type	W
Reset	IDCODE upon QTLR
5 4 3 2 1 0	
INSTRUCTION	

Table 27-9. BP

Description	The bypass register is a 1 bit register. Whatever value is scanned in TDI is preserved and scanned out of TDO one ITCK cycle later.
Type	RW
0	
BYPASS	

Table 27-10. TAPID

Description	The device identification register allows the manufacturer, part number, and version of a component to be determined through the TAP. The device identification register is scanned in response to the IDCODE instruction. This allows the manufacturer, part number, and variant for the component to be read in a serial binary form.
Type	R

0	CAPA0	A value of 1 indicated Reduced Tclk Mode is instantiated	R	-

⁽¹⁾ TI internal data

Table 27-13. CONNECT

Description	The Connect Register serves 2 purposes. First, it is used to guard use of most IR instructions. This prevents noise, hot connecting an emulator cable, or accidental scan by a miss configured scan controller, from causing test, debug, or boundary scan operations from mistakenly engaging debug functions. Secondly, this register can be used to signal that a debugger is connected and that emulation logic should be powered and enabled.							
Type	R (ARST)							
7	6	5	4	3	2	1	0	
WRITE	RESERVED				CONNECTKEY			

Bits	Field Name	Description	Type	Reset
7	WRITE	Must be 1 to write the Connect Key. A value of 0 is a read. When read, a value of 0 is returned.	R (ARST)	0b
6:4	RESERVED	Reserved, read return reset value	R (ARST)	000b
3:0	CONNECTKEY	When this field holds the key-code of 1001, the scan controller is considered to be connected. All other values are the not-connected state. In this state, only a limited number of IR instructions are valid.	R (ARST)	0110b

27.2.4.6.3.1 TAP_ROUTING_REG Description

[Table 27-14](#) and [Table 27-15](#) describe the TAP_ROUTING register and the mode block selection, respectively.

Table 27-14. TAP_ROUTING

TAP_ROUTING	RESERVED ADVANCERTCKTIMING RESERVED UNNATURALSYSRESET REDUCEDTCK SYSTEMSTATUS FREERUNNINGEMUL RESERVED CLEARALLEXFLAG GLOBALRELEASEMIR KEEPPOWERINTLR TDOALWAYSSOUT RESERVED DEVICETYPE SYSTEMRESET

Bits	Field Name	Description	Type	Reset
31:24	TAP_ROUTING	See Table 27-14 .	RW	-
23:18	RESERVED	Reserved, Read return reset value, write reset value for further compatibility	R	0x0 (ARST)
17	ADVANCERTCKTIMING	When 0, the ICEPick clock voting logic is configured so RTCK lags ITCK. When 1, the ICEPick clock voting logic is configured so RTCK has same timing as ITCK	RW	0 (ARST)
16	RESERVED	Reserved, Read return reset value, write reset value for further compatibility	R	-
15	UNNATURALSYSRESET	When 0, the system-reset state is consistent with the application controls. When 1, the system-reset state is not consistent with the application controls due to emulation actions or controls.	R	-

Bits	Field Name	Description	Type	Reset
14	REDUCEDTCK	When 0, the ICEPick clock voting logic is configured to operate upto the TCLK input frequency. When 1, the ICEPick clock voting logic is configured to operate upto the TCLK input frequency when no debug TAPs are selected.	RW	0 (ARST)
13	SYSTEMSTATUS	This bit reflects the value of a system status signal.	R	-
12	FREERUNNINGEMUL	This bit drives the FreeRunEmul output port and is used to configure ICECrusher modules for operation with an emulator which has a free running TCLK.	RW	0 (ARST)
11	RESERVED	Reserved, Read return reset value, write reset value for further compatibility	R/W	0 (ARST)
10	CLEARALLEXEFLAG	When a 1 is written, the latched value of all run bits in all secondary TAPs is cleared back to 0. Writing a 0 has no effect.	W	0 (ARST)
9	GLOBALEXEMASK	When 0, the value in the Secondary Debug TAP Register ExecuteAction bit is immediately applied to the secondary TAP and module. When 1, the run signal to the terminal is held at 0. After several secondary TAP's run bit have been set while this bit is 1, changing this bit to 0 will cause all of the secondary TAP to see the run signal at the same time.	RW	0 (ARST)
8	GLOBALRELEASEWIR	When a 1 is written to this bit and the device is held in reset due to the GlobalWaitInReset signal, the GlobalWaitInReset signal is deasserted. This is a self-clearing bit. Writing a 0 has no effect.	R/W	0 (ARST)
7	KEEPPOWERINTLR	When 1, the ICEPick logic remains powered at all times. When 0, the ICEPick logic may be powered down in the Test-Logic-Reset state if ICEPick is visible and TMS is 1.	RW	0 (POR)
6	BLOCKSYSRESET	When 1, the device system reset signal is blocked.	RW	0 (ARST)
5	TDOALWAYSOUT	When 1, the device level TDO pin will always be driven (in output mode) regardless of the TAP state. When 0, the device level TDO pin will be influenced by the current TAP state in compliance with the IEEE1149.1 specification (either output or Hi-Z mode)	RW	0 (POR)
4	RESERVED	Reserved, write reset value for further compatibility	W	0 (POR)
3:1	DEVICETYPE	Device Type.	R	011b
0	SYSTEMRESET	Emulator controlled System Reset. This signal provides the scan controller with the ability to assert the system warm reset. When a 1 is written, this behaves as if the external chip warm reset signal had been momentarily asserted. This signal does not reset any emulation logic. This is a self-clearing bit. This is cleared by the assertion of the reset requested. Writing a 0 has no effect.	RW	0 (ARST)

Table 27-19. LINKING_MODE

Description		This register control link features of the ICEPick module														
Type	RW															
31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0													
TAP_ROUTING	RESERVED	SPONDISCOFLAG	DESELECTMODE	KEYSEQUENCE	RESERVED	TAPLINKMODE	ActivateMode									

Bits	Field Name	Description	Type	Reset
31:24	TAP_ROUTING	See Table 27-14 .	RW	-
23:19	RESERVED	Reserved, Read return reset value, write reset value for further compatibility	R	0x0 (ARST)

Bits	Field Name	Description	Type	Reset
18	SPONTDISCOFLAG	This flag is set if the TAPs are spontaneously removed from the scan chain or if a selected TAP loses power. It also forces the TDO output to HiZ. Writing a 1 to this bit clears it. Writing a 0 has no effect.	RW	0 (POR)
17:16	DESELECTMODE	See Table 27-20 .	RW	0 (POR)
15:6	KEYSEQUENCE	When the TAPLinkMode is set to "key sequence", this field contains the "key sequence pattern" that will make the ICEPick TAP visible again. 0x2CD is the recommended value. Another 10-bit sequence may be used. During KeySequence detection, LSB of the Key sequence should be shifted into TDI first.	RW	0 (POR)
5:4	ESERVED	Reserved, Read return reset value, write reset value for further compatibility	R	0
3:1	TAPLINKMODE	See Table 27-21 .	RW	0 (POR)
0	ActivateMode	When a 1 is written to this bit, the currently selected TAPLinkMode is activated. ICEPick will link the TAPs according to these settings when the ICEPick TAP is advanced to Run-Test/Idle with any opcode in the IR. When in key-sequence mode, this bit is automatically cleared when the key sequence is detected.	RW	0 (POR)

NOTE: These registers are updated when entering the Update DR state, but the action that results from the update occurs when entering the Run Test/Idle state.

Table 27-20. DESELECTMODE Values

Value	Mode	Behavior
00	Stay-selected	Even though a selected secondary TAP becomes inaccessible, the set of selected TAPs does not change. Scan to any and all modules may not be possible.
01	Reserved	Acts like Stay-Selected
10	Reserved	Acts like Stay-Selected
11	Auto-deselect	When a selected secondary TAP becomes inaccessible due to power constraints, all secondary TAPs are deselected. TDO is forced to HiZ.

Table 27-21. TAPLINKMODE Values

Value	Mode	Behavior
000	Always-first	The ICEPick TAP always exists and is linked as the TAP closest to TDI.
001	Reserved	Reserved (behaves like Always-first)
010	Key-Sequence	When this mode is activated, the ICEPick TAP is no longer visible. The selected secondary TAPs are connected between the device TDI and TDO. Although the ICEPick TAP is not visible, it continues to advance state in step with the other selected TAPs. In this sense it is a shadow TAP. When in the Run Test Idle state, a special address can be scanned that will make the ICEPick TAP visible again.
011	Disappear-forever	Once activated, the ICEPick TAP is no longer visible between the device TDI and TDO. Only a power-on reset will make the TAP visible again.
100	Reserved	Reserved (behaves like Always-first)
101	Reserved	Reserved (behaves like Always-first)
110	Key Sequence with Forwarding	This mode operates in the same manner as the KeySequence mode except that any values shifted in during the Run Test Idle state are driven out the device TDO. The device TDO pin is driven during RunTest Idle.
111	Reserved	Reserved (behaves like Always-first)

27.2.4.6.3.1.2 Debug TAP Linking Control Block

The debug TAP linking block contains the control and status registers used in the selection of secondary TAPs into the master scan path. Up to 16 secondary TAPs can be supported. Each TAP has its own debug TAP control and status register.

[Table 27-22](#) shows the registers available in the ICEPick control block and the value of the TAP_ROUTING_REG[27:24] bit field used to access them.

Table 27-22. Debug TAP Linking Control Block Registers

Register	Register Name	Description
0x0	SDTR0	Secondary debug TAP 0 register
0x1	SDTR1	Secondary debug TAP 1 register
0x2	SDTR2	Secondary debug TAP 2 register
0x3	SDTR3	Secondary debug TAP 3 register
0x4	SDTR4	Secondary debug TAP 4 register
0x5	SDTR5	Secondary debug TAP 5 register
0x6	SDTR6	Secondary debug TAP 6 register
0x7	SDTR7	Secondary debug TAP 7 register
0x8	SDTR8	Secondary debug TAP 8 register
0x9	SDTR9	Secondary debug TAP 9 register
0xA	SDTR10	Secondary debug TAP 10 register
0xB	SDTR11	Secondary debug TAP 11 register
0xC	SDTR12	Secondary debug TAP 12 register
0xD	SDTR13	Secondary debug TAP 13 register
0xE	SDTR14	Secondary debug TAP 14 register
0xF	SDTR15	Secondary debug TAP 15 register

Table 27-23. SDTRj

Description	There is a separate Secondary Debug TAP Register (SDTR) for each secondary TAP (j = 0 to 15).															
Type	RW															

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAP_ROUTING								BLOCKNTRST	RESERVED	POWERLOSSDETECTED	INHIBITSLEEP	TAPPOWER	UNNATURALRESET	INRESETANDRELEASEWIR	RESETCONTROL	DEBUGENABLE	DEBUGMODE	DEBUGANDEXECUTE	VISIBLETAP	SELECTTAP	POWERDOWNDESIRED	FORCEPOWER	POWER	CLOCKDOWNDESIRED	FORCEACTIVE	CLOCK	CLOCK	TAPPRESENT	TAPPRESENT		

Bits	Field Name	Description	Type	Reset
31:24	TAP_ROUTING	See Table 27-14 .	RW	-
23	BLOCKNTRST	When this bit is 0, the nTRST signal for this secondary TAP follows the device level nTRST. When this bit is 1 and the TAP is deselected, the nTRST signal for this secondary TAP is held high.	RW	0 (ARST)
22	RESERVED	Reserved, read return reset value.	R	0
21	POWERLOSSDETECTED	When this bit is 1, the module associated with this TAP has had its power turned off. Once a power loss has been detected, this bit will remain 1 until manually cleared by writing to this bit. Writing a 1 to this bit clears this latched value back to 0. Writing a 0 has no effect.	R	0 (ARST)

ICEPick Module

www.ti.com

Bits	Field Name	Description	Type	Reset
20	INHIBITSLEEP	When 0, this bit does not influence the clock and the power settings to the module. While this bit is 1, if power or clock for TAP's module is not allowed to be turned off once turned on. The value read does not reflect the value written until the power and clock controller has acted upon a change in the written value.	RW	0 (ARST)
19	TAPPOWER	When 0, the module TAP power is off. When 1, the module TAP power is on.	R	-
18	UNNATURALRESET	When 0, the warm-reset state is consistent with the application controls. When 1, the warm-reset state is not consistent with the application controls due to emulation actions or controls.	R	-
17	INRESETANDRELEASEWIR	Read 1, the module(s) controlled by the secondary TAP is in the reset state. Read 0, the module(s) is not in reset. When a 1 is written to this bit and the module is held in reset due to the WaitInReset bit, the module reset is released. This only occurs if WaitInReset is 1 and it is the only cause for holding the module in reset. This is a self-clearing bit. Writing a 0 has no effect.	RW	0 (ARST)
16:14	RESETCONTROL	Override the application controls of the functional warm reset to a module. See Table 27-24 .	RW	0 (ARST)
13	DEBUGENABLE	When 1, the module(s) associated with this secondary TAP has its debug logic enabled. This is referred to as debug enable or connect on some modules. When 0, the debug logic is allowed to be turned off.	RW	0 (ARST)
12:11	DEBUGMODE	Specify the debug mode of the module upon power-on-reset. See Table 27-25 .	RW	0 (ARST)
10	DEBUGANDEXECUTE	Read 0, all processors (modules) on this secondary TAP are in execution state. Read 1, one or more processors (modules) on this secondary TAP have entered a state where debugger interaction is required. Writing a 1 enables the module to take action on a preloaded execution command, such as run. This bit may be gated by the GlobalExecuteMask. Writing a 0 has no effect.	RW	0 (ARST)
9	VISIBLETAP	When 1, the TAP is currently selected and visible in the active scan chain.	R	-
8	SELECTTAP	While 1, the TAP is selected for inclusion in the master scan path. While 0, the TAP is not selected. The effects of changing this bit do not take place until the Run-Test-Idle state is reached.	RW	0 (ARST)
7	POWERDOWNDESIRED	When 0, the module's power is not being affected by the emulation controls or actions. When 1, the power would normally be turned off to the module if it were not for emulation controls.	R	-
6	FORCEPOWER	When 0, this bit does not influence the module power state. When 1, the TAP and its module are held in a operational powered state regardless of whether the TAP is selected or not. The value read does not reflect the value written until the power controller has acted upon a change in the written value.	W	0
5	POWER	When 0, the module power is off. When 1, the module power is on.	R	-
4	CLOCKDOWNDESIRED	When 0, the module clock state is not being affected by emulation controls or actions. When 1, the clock would normally be turned off to the module if it were not for emulation controls.	R	-

Bits	Field Name	Description	Type	Reset
3	FORCEACTIVE	When 0, this bit does not influence the module's power or clock settings. When 1, the clock for TAP's module is forced on. It is implied that this control will also turn on the power. The value read does not reflect the value written until the power and clock controller has acted upon a change in the written value.	W	-
2	CLOCK	When 0, the module clock is off (Idle). When 1, the module clock is on.	R	-
1	TAPACCESSIBLE	When 0, the TAP cannot be accessed. When 1, the TAP can be accessed.	R	-
0	TAPPRESENT	When 0, there is not a TAP assigned to this spot. When 1, this TAP exists in the device.	R	-

Table 27-24. RESETCONTROL Values

Value	Command	Description
000	Normal Operation	Reset operates under the normal control of the application or device controls.
001	Wait-in-reset (extended reset)	The module(s) controlled by this secondary TAP will remain in the reset state once the reset is asserted. This bit alone does not reset the processor.
010	Block Reset	Warm-reset to the module is blocked. At this point, only emulation reset controls will work.
011	Block and Assert Reset	Assert and hold the reset to the module.
1xx	Cancel	Cancels reset command lockout

Table 27-25. DEBUGMODE Values

Value	Debug Mode	Description
00	Default mode	The processor will use whatever debug mode is its default mode.
01	Monitor mode	The debug features of the processor will be configured for monitor mode.
10	Halt mode	The debug feature of the processor will be configured for halt or stop mode.
11	Real-time halt mode	The debug features of the processor will be configured for real-time halt mode.

27.2.5 ICEPick Basic Programming Model

27.2.5.1 Basic Initialization

The following sequence connects the ICEPick to the debugger and configures ICEPick rtck behavior:

1. Connect ICEPick:
 - Select IR scan.
 - Send the CONNECT instruction in IR scan (000111).
 - Select DR scan.
 - Send the following value in DR scan 10001001 (write and connect key).
 - At the update DR, the ICEPick is in connected state.
2. Configure ICEPick:
 - Select IR scan.
 - Send the ROUTER instruction in IR scan (0000010).
 - Select DR scan.
 - Send the following value in DR scan (see [Table 27-18](#)):
 - WRITE (bit 32) = 1
 - BLOCK (bit field [31:28]) = 0x0, block 0 is ICEPick control.
 - REGISTER (bit field [27:24]) = 0x0
 - ADVANCERTCKTIMING (bit 17) must be configured.

- FREERUNNINGEMUL (bit 12) must be configured.
- Configure other bit field if needed.
- At the update DR, the ICEPick is properly configured.

27.2.5.2 Adding a TAP in the Debug Chain

The following sequence adds a new TAP in the debug chain:

1. Select IR scan.
2. Send the ROUTER instruction in IR scan (000010).
3. Select DR scan.
4. Send the following value in DR scan (see [Table 27-18](#)) to enable power and clock for the TAP:
 - WRITE (bit 32) = 1
 - BLOCK (bit field [31:28]) = 0x2; bloc 2 is Debug TAP Linking Control.
 - REGISTER (bit field [27:24]) = TAP number, select the TAP to be added to the chain; see [Table 27-2](#) for more information.
 - FORCEACTIVE (bit 3) = 1, enable the TAP power and clock.
 - FORCEPOWER (bit 6) = 1, force the TAP power to ON state regardless of whether the TAP is selected or not.
 - INHIBITSLEEP (bit 20) = 1, force the TAP clock to be active.
5. Read back the value in next DR scan:
 - WRITE (bit 32) = 0
 - BLOCK (bit field [31:28]) = 0x2; block 2 is Debug TAP Linking Control.
 - REGISTER (bit field [27:24]) = TAP number , select the TAP to be added to the chain; see [Table 27-2](#) for more information.
6. Check if the FORCEACTIVE, FORCEPOWER, and INHIBITSLEEP bits are set to 1.
7. Send the following value in DR scan (see [Table 27-18](#)) to enable debug mode:
 - DEBUGENABLE (bit 13) = 1; enable the TAP debug.
 - DEBUGMODE (bit field [12:11]) = MODE; see [Table 27-25](#) for available debug modes.
8. Read back the value in next DR scan:
 - WRITE (bit 32) = 0
 - BLOCK (bit field [31:28]) = 0x2; block 2 is Debug TAP Linking Control.
 - REGISTER (bit field [27:24]) = TAP number , select the TAP to be added to the chain; see [Table 27-2](#) for more information.
9. Check if DEBUGENABLE and DEBUGMODE bit are well set.
10. Send the following value in DR scan (see [Table 27-18](#)) to add the TAP in the chain:
 - SELECTTAP (bit 8) = 1; add the TAP in the chain.
11. Go in Run Test Idle (RTI) so the change takes effect and the TAP is added to the chain (a wait may be needed).

When the TAP is added to the chain, DR and IR are longer (ICEPick length + new TAP).

To write in IR for the new TAP, write BYPASS in ICEPick IR so the next DR is not taken into account and is only 1 bit for ICEPick.

27.3 SDTI Module

This section describes the SDTI in the device.

27.3.1 SDTI Overview

SDTI is a main component that implements system trace in the device. The SDTI is connected to the L4_EMU and mapped to the EMU domain. L4_EMU is accessible by the MPU and the digital signal processor (DSP). Figure 27-8 shows the SDTI in the device.

Figure 27-8. SDTI in the Device

The SDTI provides real-time software tracing to device. It generates software messages, which are encoded as defined in the custom protocol.

NOTE: The custom protocol is not MIPI® compliant.

Messages are a way for software to export crucial information and thus provide a high level of visibility on system behavior (task entry, procedures calls, system status, test signatures, and memory allocation); 256 message channels, which can be allocated between software components, are available.

Messages are exported to trace receivers through a serial interface.

SDTI has its own local, dedicated first in first out (FIFO) buffering to allow trace capabilities concurrent to ETM trace captured in ETB.

SDTI implements only trace export from device to remote PC through an emulator box. There is no receive path feature in the SDTI. A standard asynchronous serial port (UART, 8 data bits, 1 stop-bit, no parity) can be used as a back-channel to send emulation related control requests and data back to device.

27.3.2 SDTI Environment

The trace interface has four trace data pins and one trace clock, as shown in Table 27-26.

Table 27-26. SDTI Pins

Port	Width	I/O (¹)	Reset Value	Description
sdти_clk	1	O	1	Trace interface clock output
sdти_txd	4	O	0000	Trace interface data

⁽¹⁾ I = Input; O = Output

NOTE: 1, 2, and 4-bit serial interface configurations are supported.

Serial interface is a dual-edge interface (new sdti_txd data is available with rising and falling edge of sdti_clk). Interface can be also configured in single-edge mode where data are available with the falling edge of sdti_clk. This can be configured in the [SDTI_SCONFIG\[4\] SINGLEEDGE](#) bit

Serial interface operates in clock stop regime (the serial clock is not free-running), when there is no trace data there is no trace clock.

27.3.2.1 SDTI Pins Configuration Mode

Figure 27-9 through Figure 27-11 show the SDTI connected with an emulator box in four, two, and one data pin configuration, respectively. The number of pins used for transmission can be configured in the [SDTI_SCONFIG\[6:5\] TXDSIZE](#) bit field.

Figure 27-9. SDTI Connected in Four Data Pins Mode

sdti-002

Figure 27-10. SDTI Connected in Two Data Pins Mode

sdti-003

Figure 27-11. SDTI Connected in One Data Pin Mode

sdti-004

27.3.2.2 SDTI Protocol

The SDTI serial interface is a dual-edge, 4-pin serial interface used to connect the device to trace receivers (for example, XDS560T).

Trace receivers sample trace data on each clock edge. The trace clock (SDTI_CLK) starts with a falling edge. The sdti_clk signal is forced high until the first data value is available.

Serial interface operates in clock stop mode; when there is no data available, the clock stops. SDTI_CLK is not a free-running clock.

To support older trace receivers, serial interface can be placed into single-edge mode where data is captured with the falling edge of the trace clock ([SDTI_SCONFIG\[4\] SINGLEEDGE = 1](#)).

[Figure 27-12](#) shows the SDTI dual-edge serial interface waveform.

Figure 27-12. Dual-Edge Clock Waveform

[Figure 27-13](#) shows the SDTI single-edge serial interface waveform.

Figure 27-13. Single-Edge Clock Waveform

The SDTI serial interface is configurable to support one, two, and four data bits operation. Depending on the configuration, trace data is exported on sdti_txd[0], sdti_txd[1:0], or sdti_txd[3:0].

Serial clock frequency is selected in the SDTI serial configuration register (the [SDTI_SCONFIG\[3:0\] SDTISCLKRATE](#) bit field). Programmers must select the correct serial frequency (choose division factor) based on the functional clock frequency.

27.3.2.3 SDTI Data Format

[Table 27-27](#) summarizes the message types.

Table 27-27. SDTI CPU Software Messages

Type	Identification
CPU1 timestamped message	001D DAtt
CPU1 message	010D DA00
CPU2 timestamped message	011D DAtt
CPU2 message	110D DA00

NOTE:

- DD: Data length
 - 00 = 8-bit data
 - 01 = 16-bit data
 - 10 = 32-bit data
 - 11 = Reserved
- A: Address length
 - 0 = No address
 - 1 = 8-bit address
- tt: Time stamp bits always zero in SDTI

[Table 27-28](#) to [Table 27-31](#) show detailed message structure.

Table 27-28. CPU1 Timestamped Message

Description	Format		
Header	001D DA00		
Timestamp	0

27.3.3 SDTI Integration

Figure 27-14 shows the internal connections between the SDTI and other modules in the device.

Figure 27-14. SDTI Integration

27.3.3.1 Clocking and Reset

27.3.3.1.1 Clocks

The SDTI receives two clocks:

- SDTI_ICLK: The L4_EMU clock for the interface and the functional clock for SDTI
- SDTI_FCLK: The serial interface base clock, which is always twice as fast as SDTI_ICLK

Trace serial interface (sdti_clk) runs on a clock generated in SDTI. The serial interface clock is derived from SDTI_FCLK in programmable clock divider.

Divider factors for serial clock generation are referenced to SDTI_ICLK. These factors range from 1 to 10. SDTI_FCLK always has an internal clock that runs twice as fast as the serial clock selected through division factors, which is used as a base clock in dual-edge serial transmitters.

27.3.3.1.2 Reset

The SDTI is reset with hardware POR. All SDTI registers are asynchronously reset. The SDTI remains operational and with its setup preserved when a warm reset is triggered to export the trace history to the trace controller. This trace history may contain key information from a debug perspective for understanding the root cause of the warm reset.

The PRCM module delivers the EMU_RSTPOWRON reset qualifier and the RESET signal to distinguish power on from a warm (soft) reset.

The application or debugger software can reset the SDTI at any time by writing 1 to the **SDTI_SYSCONFIG[1]** SOFTRESET bit. This puts the SDTI in the same reset state as a hardware reset.

27.3.4 SDTI Functional Description

27.3.4.1 SDTI Block Diagram

Figure 27-15 is a block diagram of the SDTI.

Figure 27-15. SDTI Block Diagram

sdti-008

The SDTI is configured through the L4 EMU target interface.

All SDTI registers are 32-bit (double word) aligned. For information about handling non-aligned addresses, supported/not supported byte enables, access to nonexistent memory address, reads to write-only registers, and writes to read-only registers, see [Section 27.3.4.9, SDTI Error Handling](#).

The SDTI is active (enabled) when enabled through claim procedure. For information about the claim procedure, see [Section 27.3.4.2, SDTI Ownership](#). When enabled, SDTI generates messages or test patterns and exports them through the serial interface.

27.3.4.2 SDTI Ownership

Some SDTI resources can be owned by the application or by the debugger. Ownership is required to configure or program the SDTI. Ownership determines whether write access is granted to the SDTI configuration registers. SDTI resource ownership is exclusive. Hence, simultaneous use of SDTI resources by both debugger and application is not permitted. However, the debugger can forcibly seize ownership of SDTI resources.

NOTE: Read access does not require ownership; therefore, either party can read any SDTI register with or without ownership.

The application and the debugger cannot simultaneously write to the following SDTI resources (also called units):

Window control register (accompanied by the serial configuration register and the test control register)

27.3.4.2.1 Ownership States

Ownership has three basic states:

- Available: The unit has not been claimed.
- Claimed: The unit has been claimed.
- Enabled: The unit is enabled by the owning party.

27.3.4.2.1.1 Available State

The SDTI is set to available state when one of two conditions occurs:

- The state is available when POR is asserted.
- The state is available if the SDTI is owned by the debugger and the emulator is disconnected.

NOTE: A warm reset has no effect on the operation of the SDTI. An emulator disconnect has no effect when the application owns the unit.

27.3.4.2.1.2 Claimed State

The SDTI is in claimed state when the debugger or the application claims it. The claimed state provides exclusive access to the owner. The other party is not permitted write access to the unit until the owning party releases the claim. Once a unit has been claimed, only the owner can write to the other resources controlled by the claim.

The debugger, however, is allowed to forcibly seize control of a unit, if already claimed by the application, by setting the [SDTI_WINCTRL\[29\]](#) DEBUGGEROVERRIDE bit.

27.3.4.2.1.3 Enabled State

The SDTI enters into enabled state when it is activated. The owner can continue to write to other resources while the SDTI is enabled.

27.3.4.2.2 Ownership Commands

Ownership of SDTI resources is managed through the [SDTI_WINCTRL\[31:30\]](#) OWNERSHIP bit field. [Table 27-32](#) lists the ownership commands.

Table 27-32. Ownership Commands

Command	Meaning	Description
00	Release ownership	Release ownership of SDTI. The release command is accepted only from the owner.
01	Claim ownership	Claim access to the SDTI. The claim command is successful only if the unit is available or the requester is the debugger and the SDTI_WINCTRL[29] DEBUGGEROVERRIDE bit is high.
10	Enable unit	Activate the SDTI for use. The enable command is accepted only from the owner.
11	No operation	The NOP command does not affect ownership or claim state.

27.3.4.2.3 Claim Bits

The 4 claim bits are implemented in the [SDTI_WINCTRL](#) register, as shown in [Table 27-33](#).

Table 27-33. Claim Bits

Field	Width	R/W	Reset	Description
Ownership[1:0]	2	R	00	Read to get current ownership status. The claim status encoding is (0 = available; 1 = claimed; 2 = enabled; 3 = reserved)
			W	Send command to modify ownership state. See Table 27-32 . ⁽¹⁾
DebuggerOverride	1	R	1	A read from the DEBUGGEROVERRIDE bit returns 1.
			W	This qualifier bit is used with the debugger claim request. The DEBUGGEROVERRIDE bit is not registered. When written with DEBUGGEROVERRIDE set to 1, a claim request by the debugger is granted, regardless of the ownership status of the unit. When written with DEBUGGEROVERRIDE set to 0, the claim request is granted only if the unit is available.
CurrentOwner	1	R	0	This value reflects the SDTI ownership when the register is in a nonavailable state. 0 = Debugger owns resource. 1 = Application owns resource.

⁽¹⁾ A successful command causes these bit values to reflect the new state.

27.3.4.2.4 Claim Resets

When the SDTI is owned by the debugger, the resource is released if the debugger is disconnected.

If the SDTI is owned by the application and the processor enters debug state, the resource continues to belong to the application. The SDTI is not sensitive to debug state.

If the SDTI ownership is released while data are in the SDTI FIFO, the serial interface continues to export data until the FIFO is drained.

27.3.4.3 Trace Data Collection

The messages allow the application software to export, through the serial trace interface, key information that provides high-level visibility on system behavior (task entry, system status, test signature, and memory allocation); 256 message channels are available, starting at 0x5460 0000.

To minimize cycle overhead, the generation of messages is implemented through a dedicated address window. Each write to an address within the window triggers a message.

To facilitate memory management unit (MMU) use for channel enabling and disabling, channel to memory address mapping is organized as follows:

- Each of the 256 channels is allocated 4KB of memory. This corresponds to an MMU page.
- Within 4KB, CPU1 and CPU2 channels are interleaved:
 - 1KB CPU1 message
 - 1KB CPU1 timestamped message
 - 1KB CPU2 message
 - 1KB CPU2 timestamped message
- Each write to addresses within the first KB of channel space triggers a CPU1 message.
- Each write to addresses within the second KB of channel space triggers a CPU1 timestamped message.
- Each write to addresses within third KB of channel space triggers a CPU2 message.
- Each write to addresses within fourth KB of channel space triggers a CPU2 timestamped message.

When there is a write in that range, SDTI hardware decodes the access and stores the address decoded as channel, CPU1/2, and message/ timestamped message, along with the data and access size.

The message header is determined from the accessed address and access type (1, 2, or 4 bytes).

Trace matching for CPU1 and CPU2 message generation can be globally enabled or disabled in the [SDTI_WINCTRL](#) register.

Although timestamped messages are supported, the SDTI does not implement time-stamping logic, and all time-stamp-related bit fields in timestamped message are always zeroed.

Timestamped messages can be used as an end message marker. Trace software generates a timestamped message on the same channel with previously exported non-timestamped messages as an end message marker.

There is no MConn-ID supported on L4_EMU and thus no capability to differentiate accesses from various initiators. Each access to the CPU1 address space generates a CPU1 message/ timestamped message, regardless of the initiator. The same applies for CPU2 message generation.

Debugger accesses are differentiated from other initiators by using the MRegDebug qualifier. If enabled through the [SDTI_WINCTRL\[2\]](#) DEBUGGERTRACEEN bit, debugger accesses to the trace matching window generate a CPU1 or CPU2 message, depending only on the address accessed. The external trace receiver cannot differentiate between debugger-initiated and application-initiated trace. Otherwise, debugger writes to the trace matching address window do not generate messages.

Burst writes not supported by L4_EMU burst from level 3 (L3) are split into single writes in the L3/L4_EMU bridge (for example, originating from STM instruction), with each of them triggering a separate message.

As a simple compression scheme for serial bandwidth improvement, in case of consecutive writes to the same message channel, the channel address is omitted from a message. For particular message encoding, see [Section 27.3.2.3, SDTI Data Format](#). Because initiators are not differentiated on L4_EMU compression, the scheme is based only on the address accessed. Consecutive accesses to the same address originating from various initiators activates compression.

The SDTI does not lose messages. If it is necessary, the SDTI stalls its interface until there is enough space in the FIFO to store new messages.

A valid write access to the trace address matching window with an all-zeroes byte-enable pattern do not trigger a message.

The SDTI starts to output serial data as soon as it has at least one captured line in the FIFO.

27.3.4.4 Trace Buffer FIFO

The SDTI FIFO is organized as listed in [Table 27-34](#).

Table 27-34. FIFO Data Organization

Field	Size (Bits)
Timestamped message (end message marker)	1
CPU1/CPU2	1
Channel number	8
Data size (in bytes)	2
Data	32

When full, the SDTI FIFO stalls L4_EMU by not acknowledging the write access. When FIFO room becomes available, the SDTI can capture a new message.

The SDTI FIFO status can be polled by reading the [SDTI_SYSSTATUS\[8\]](#) FIFOEMPTY bit. FIFOEMPTY reflects the state of SDTI buffering, including the SDTI FIFO and serial interface shift register. When read as 1, there is no more data in the SDTI to be exported.

Check the SDTI FIFO status before powering down the EMU domain or changing the serial interface configuration.

27.3.4.5 Serial Interface Test Pattern Generation

To support calibration, tuning, and testing, the SDTI includes a test pattern generator, which drives the serial interface when testing mode is selected.

When serial interface test mode is selected and the SDTI is enabled, the SDTI continuously exports test patterns until it is disabled. For the test mode enable procedure, see [Section 27.3.5.2, Serial Interface Test Mode Setup](#).

[Table 27-35](#) lists the different patterns that are supported.

Table 27-35. Test Pattern Format

Pattern Name	Pattern Example
Simple A	0x5, 0xA
Simple F	0x0, 0xF
Walking ones	0x0, 0x1, 0x2, 0x4, 0x8
Ramp (incremental counter)	0x0, 0x1, 0x2,..., 0xF, 0x0,...
Pseudo random (LFSR)	-

Test patterns are exported in chunks that are sized to the internal serial interface data bus. For example, if the serial interface is configured as 4-wire, test patterns are exported in a multiple of four patterns. For 2-wire interface, patterns are exported in a multiple of 8 patterns; for 1-wire interface, patterns are exported in a multiple of 16 patterns.

27.3.4.5.1 Simple Patterns

Simple A and F patterns can be used for calibration, observing cross-talk, and ground bounce.

These patterns depend on the interface width selected. [Table 27-36](#) summarizes the patterns generated.

Table 27-36. Simple Test Pattern

Interface Width (Bits)	Pattern A	Pattern F
1	0, 1	0, 1
2	01, 10	00, 11
4	0x5, 0xA	0x0, 0xF

27.3.4.5.2 Walking Ones

The walking-ones pattern can be used to verify connectivity and correct bits that are being driven.

This pattern depends on the interface width selected. [Table 27-37](#) lists the patterns generated.

Table 27-37. Walking Test Pattern

Interface Width (Bits)	Pattern
1	0, 1
2	00, 01, 10
4	0x0, 0x1, 0x2, 0x4, 0x8

27.3.4.5.3 Ramp Pattern

The ramp pattern can be used to verify that no data is lost at the trace receiver.

The ramp pattern generator is implemented as a 4-bit up counter.

27.3.4.5.4 Pseudo Random (LFSR) Pattern

The linear feedback shift register (LFSR) pattern can be used to verify the transporting of SDTI data across the entire software stack without loss of data.

Pseudo random data is obtained from the 16-bit LFSR. The shift register implements the following polynomial:

$$G(x) = x^{16} + x^{15} + x^{13} + x^4 + 1$$

LFSR is initialized with a 0xFFFF each time pattern generation is enabled.

This LFSR can provide a 64-K long unique data sequence of 16-bit data. For the LFSR pattern, the LSBs are output (the lower 4 bits are output in the case of a 4-bit interface). The upper bits keep the pattern unique for 64-K samples.

The first six values of LFSR are:

1. 0xFFFF
2. 0x5FEF
3. 0xBFDE
4. 0xDFAD
5. 0x1F4B
6. 0x3E96

27.3.4.6 CoreSight Integration Mode

As a CoreSight-compliant peripheral, the SDTI provides an integration mode where the interface input ports can be probed and the output ports can be driven. The following CoreSight integration registers are used to set up and use this mode:

- [INT_MODE_CTRL_REG](#)
- [INT_OUTPUT_REG](#)
- [INT_INPUT_REG](#)

The [CLAIM_TAG_SET_REG](#) register is included for CoreSight compliance. Normally, the lower 4 bits are used for claiming and releasing debug components. The SDTI, however, implements a more sophisticated claim mechanism. These bits can be used as software semaphores to help manage the debug resources, although the claim-and-enable mechanism of the SDTI resources must still be used. Writing 1 to one of the set bits causes the corresponding bit in the claim tag value word to go high.

The [CLAIM_TAG_CLEAR_REG](#) bits can be used as software semaphores to help manage the debug resources. Writing 1 to one of the CLEAR bits causes the corresponding bit in the claim tag value word to go low. Reading this register returns the value of the claim tag.

27.3.4.7 Serial Interface Clock Generation

The `sdti_clk` is derived from `SDTI_FCLK` with a programmable clock divider controlled by the [SDTI_SCONFIG\[3:0\]](#) `SDTISCLKRATE` bit field. [Table 27-38](#) shows the divider for the value of the [SDTI_SCONFIG\[3:0\]](#) `SDTISCLKRATE` bit field.

Table 27-38. `sdti_clk` Divider Value

SDTISCLKRATE Value	Division Value
0x0	Division by 1
0x1	Division by 1
0x2	Division by 2
0x3	Division by 3
0x4	Division by 4
0x5	Division by 5
0x6	Division by 6
0x7	Division by 7
0x8	Division by 8
0x9	Division by 9
0xA	Division by 10
Others	Division by 1

27.3.4.8 SDTI Memory Mapping

[Table 27-39](#) shows the SDTI memory mapping, and [Table 27-40](#) provides channel address examples.

Table 27-39. SDTI Memory Mapping

Name	Address Offset		Address		Size
	Start	Stop	Start	Stop	
Configuration Space (Base = 0x5450 0000)

CPU2 message	51	0x33800 – 0x33BFF
CPU2 timestamped message	255	0xFFC00 – 0xFFFFF

27.3.4.9 SDTI Error Handling

The SDTI port returns the in-band error as a response in the following cases:

- Unsupported master command
- Unsupported byte enable
- Unaligned address
- Application write access to locked SDTI registers

Read and write accesses pointing to memory holes are considered as software errors, not interconnect errors. Such accesses get a valid response, do not affect the module behavior, and are not reported. In case of a read command, the returned data is zeroes.

A read from the trace matching address window is also considered a software error and returns a valid response with don't care data (all zeroes).

A write access to the trace matching window with CPU1 or CPU2 message generation disabled returns a valid response.

Read accesses are not affected by the state of the lock access register.

Debugger write accesses are never locked (affected by the state of the [LOCK_ACCESS_REG](#) register).

27.3.5 SDTI Basic Programming Model

27.3.5.1 Trace Setup

To enable trace, perform the following steps:

1. If setup is performed through application software, enable write access to the SDTI by writing unlock key to the lock access register ([LOCK_ACCESS_REG](#)).
2. Claim the SDTI through the ownership procedure.
3. Configure the serial interface.
4. Configure [SDTI_WINCTRL](#) to enable message generation.
5. Enable the SDTI through the ownership procedure.

Interface configuration (data width, serial clock selection, dual-/single-edge of operation) must be considered as static and are not to be changed on the fly. The serial interface must be properly configured before enabling trace capture and the interface configuration must not be changed while data are in the SDTI FIFO.

If the address window is disabled (CPU1 and CPU2 message generation is disabled in the [SDTI_WINCTRL](#) register while data are in the SDTI FIFO), the serial interface continues to export data until the FIFO is drained.

Write access to the disabled address window has no effect.

If SDTI ownership is released while data are in the SDTI FIFO, the serial interface continues to export data until the FIFO is drained.

If released (in AVAILABLE ownership state), the SDTI does not generate new messages.

If one trace session ends and a new session starts without a change in the interface configuration, the programming model is:

1. Disable trace.
2. Wait until SDTI FIFO is drained.
3. Enable trace and thus start a new session.

This ensures that the first message in the new session is always exported with the address field.

In case of a short disable/enable sequence (when trace is re-enabled while data from a previous session are still in the SDTI FIFO), session breaks are filtered out (disregarded). From an address compression standpoint, when compression is on, the message address field in the new session depends on the previous trace session.

Functional or message generation mode has priority over serial interface test mode (if message generation and test mode are enabled, the SDTI is in functional mode).

27.3.5.2 Serial Interface Test Mode Setup

To enable serial interface test mode, perform the following steps:

1. If setup is performed through application software, enable write access to the SDTI by writing unlock key to the lock access register ([LOCK_ACCESS_REG](#)).
2. Claim the SDTI through the ownership procedure.
3. Configure the serial interface.
4. Configure [SDTI_WINCTRL](#) to disable message generation.
5. Configure [SDTI_TESTCTRL](#) to select test pattern and test pattern generation mode.
6. Enable the SDTI through the ownership procedure.

The SDTI continues to export test patterns until one of the following occurs:

- Serial test mode is disabled.
- Message generation is enabled.
- The SDTI is released.

CAUTION

Serial interface test mode must be entered only when trace is not enabled and the SDTI FIFO is empty. Switching to serial interface test mode while trace is active leads to unpredictable results.

27.3.5.3 CoreSight Integration Mode Setup

To enable the serial CoreSight integration mode, perform the following steps:

1. If setup is performed through application software, enable write access to the SDTI by writing unlock key to the lock access register ([LOCK_ACCESS_REG](#))
2. Switch to integration mode by setting the [INT_MODE_CTRL_REG\[0\]](#) ITM bit to 1.
3. The SDTI remains in Integration mode until [INT_MODE_CTRL_REG\[0\]](#) ITM is cleared to 0.

CAUTION

Integration mode must be entered only when trace is not enabled and the SDTI FIFO is empty. Switching to integration mode while trace is active leads to unpredictable results.

27.3.5.4 SDTI Register Ownership

[Table 27-41](#) lists all the SDTI registers with their ownership and description.

Table 27-41. SDTI Register Ownership

Address Offset	Mnemonic	Description	R/W	Ownership
0x000	SDTI_REVISION	SDTI identification register	R	No ownership
0x010	SDTI_SYSCONFIG	SDTI system configuration register	R/W	No ownership

Table 27-66. LOCK_ACCESS_REG

Address Offset	0x0000 0FB0	Instance	SDTI
Physical Address	See Table 27-43	Instance	SDTI
Description	<p>Note</p> <p>This 32-bit write only register is used to lockout errant accesses by application software. When written with a value of 0xC5ACCE55, application writes to the other registers within SDTI are enabled. Any other value shall inhibit application writes (write to Lock Access Register is always enabled). Inhibited application writes shall return an error response. Debugger accesses (PIMREQDEBUG = 1) are not affected by the Lock Access Register. This register is reset to zero (locked) when POR occurs.</p> <p>SDTI_SYSCONFIG register is excluded from lock access scheme.</p>

27.4 Emulation Pin Manager

This section describes the debug pins in the device.

27.4.1 EPM Overview

The EPM manages the multiplexing of the emulation pin to the application pin manager. [Figure 27-16](#) shows the EPM in the device.

Figure 27-16. EPM Overview

For more informations about the application pin manager, see [Chapter 13, System Control Module](#).

27.4.2 EPM Integration

The EPM is in the EMU power domain and is connected to the L4 debug interconnect for register control access.

27.4.3 EPM Functional Description

27.4.3.1 EPM Overview

Some subsystems provide a debug port that can be configured to support a specific debug and trace feature. The configuration and debug source selection are done through the EPM.

At the device level, the platform shares a unique debug port. A similar mechanism allows configuring and selecting a specific debug source for each pin. This allows supporting concurrent debug features, provided that pin mapping does not conflict.

The device EPM can be programmed from the application or debugger software. A claim mechanism ensures exclusive ownership. However, the debugger can override the ownership state.

The debug port is mapped on top of a set of application pins. The device platforms provide the application software with the flexibility to map a set of peripheral interfaces to these pins. The configuration and the application source selection are done through the device application pin manager in the system control module (SCM) (for more information, see [Chapter 13, System Control Module](#)).

When the EPM is programmed to map a debug function to the debug port, the application pin manager (in the SCM) automatically selects the EPM channel.

27.4.3.2 EPM Multiplexing

EPM multiplexes multiple debug signals to the etk_xxx and jtag_emu0/1 signals. The multiplexing function is controlled by the following registers:

- [DAPC_EPM0](#)
- [DAPC_EPM1](#)
- [DAPC_EPM2](#)

Multiple signals can be controlled by a single bit field (for example, the etk_d10, etk_d9, and etk_d8

signals are controlled by the [DAPC_EPM1\[19:16\]](#) DBGP12 bit field).

[Table 27-100](#) lists the different modes supported for each pin and the bit field that controls the output mode.

Table 27-100. EPM Multiplexing

DBGP1	jtag_emu1	—	—	—	—	emu1	IO	—	O	sdти_txtd0 ⁽³⁾	O	sdти_txtd1 ⁽³⁾	O	sdти_txtd0 ⁽³⁾	O
DBGP0	jtag_emu0	—	—	—	—	emu0	IO	—	O	sdти_clk ⁽¹⁾	O	sdти_txtd0 ⁽¹⁾	O	sdти_clk ⁽¹⁾	O

⁽¹⁾ Two SDTI pins can be mapped to the same etk_#; SDTI_CLK selects the sdти_clk pin, and SDTI_DATA selects the sdти_txtd# data pin.

⁽²⁾ To map the uart1_rx pin, configuration must be done on the application pin manager (that is, SCM)

⁽³⁾ Two SDTI data share the same etk_#; sdти_txtd0 is mapped on jtag_emu1 if sdти_clk is mapped on jtag_emu0; and sdти_txtd1 is mapped on jtag_emu1 if sdти_txtd0 is mapped on jtag_emu0.

All the output pins are controlled by a 4-bit bit field that configures the current mode. Table 27-101 shows the list of modes supported and the corresponding values to enter in the EPM control bit field in the following registers:

- [DAPC_EPM0](#)
- [DAPC_EPM1](#)
- [DAPC_EPM2](#)

Table 27-102 summarizes the concurrent debug scenarios supported in the device.

Table 27-102. Concurrent Debug Interfaces

	ETM16	ETM8	Triggers	IVA	SDTI	SDTI
				HS-RTDX		
(1)(2)ETM16			x	x	x	
ETM8			x	x	x	x
Triggers	x	x		x (1)		x
IVA HS-RTDX	x	x	x (1)			x
SDTI (3)	x	x				
SDTI (2)		x	x	x		

(1) Single HS-RTDX data line concurrent with single trigger

(2) 4-pin trace data plus trace clock mapped to dedicated SDTI port

(3) Single trace data line plus trace clock mapped to jtag_emu0, jtag_emu1 pins

The jtag_emu0 debug signal routing is directly defined by the EPM CONTROL[0] setup.

The jtag_emu1 debug signal routing depends on the debug function mapped to jtag_emu1 and the debug signal routed to jtag_emu0.

The etk_clk debug signal routing depends on the debug function mapped to etk_clk and the debug signals routed to jtag_emu0 and jtag_emu.

The etk_ctl debug signal routing depends on the debug function mapped to etk_ctl and the debug signal routed to jtag_emu0, jtag_emu1, and etk_clk.

If the same debug feature is mapped to consecutive etk_d pins and the debug signal [n] is routed to etk_d[i], the debug signal [n+1] is routed to etk_d[i+1].

If different features are mapped to consecutive etk_d pins and the debug signal [x,n] is routed to etk_d[i], the debug signal [y,0] is routed to etk_d[i+1].

27.4.3.4 EPM Control Access

The EPM control registers are attached to the emulation L4 bus and can be programmed by the debugger through DAP or by the application software. Figure 27-17 shows the two accesses.

Figure 27-17. EPM Control Access

debpin-002

All access done by using DAP are considered debugger access; otherwise, they are considered application access.

27.4.3.5 Claim Procedure

The application or the debugger can own the EPM control registers. The ownership is required to configure or program the EPM. In other words, ownership determines if write access is granted to the component. EPM ownership is exclusive. Hence, simultaneous use of EPM is not permitted. However, the debugger can forcibly seize ownership of the EPM.

Claim state can be read in the [DAPC_EPM2\[31:30\]](#) CLAIMOWNERSHIP bit field. [Table 27-103](#) shows the different claim values returned by this bit field.

Table 27-103. Claim States

State	Value	Definition
Available	00	The EPM has not been claimed.
Claimed	01	The EPM has been claimed.
Enabled	10	The EPM is enabled by the owning party.
Reserved	11	Reserved

If the EPM is in a nonavailable state (the [DAPC_EPM2\[31:30\]](#) CLAIMOWNERSHIP bit field = 01 or 10), the current owner can be read in the [DAPC_EPM2\[28\]](#) CLAIMCURRENTOWNER bit.

To change claim ownership state, write a command in the [DAPC_EPM2\[31:30\]](#) CLAIMOWNERSHIP bit field. [Table 27-104](#) shows the different commands to manage EPM ownership.

Table 27-104. Claim Commands

Encoding	Command	Definition
00	Release ownership	Release EPM ownership. The release command is accepted only from the owner.
01	Claim ownership	Claim access to the EPM. The claim command is successful only if the EPM is available or requested by the debugger and the DEBUGGEROVERRIDE bit is high.
10	Enable unit	Activate the EPM for use. The enable command is accepted only from the owner.
11	No operation	The NOP command does not affect ownership or the claim state.

The debugger can force the claim procedure by writing 1 in the [DAPC_EPM2\[27\]](#) CLAIMDEBUGGEROVERRIDE bit. When this bit is set to 1, the debugger can get EPM ownership even if the application already ownership. When this bit is cleared to 0, the debugger can get EPM ownership only if the current state is Available.

27.4.4 EPM Programming Model

27.4.4.1 EPM Concurrent Debug Examples

[Table 27-105](#) through [Table 27-110](#) show different examples of concurrent debug with the corresponding EPM control field and value.

Table 27-105. Triggers

EMU Pin	Debug Mode	Debug Signal Routing	EPM Control Field	EPM Control Value
jtag_emu0	Trigger	Trigger 0	DBGPO	0001
jtag_emu1	Trigger	Trigger 1	DBGPI	0001

Table 27-106. Trigger + HS-RTDX

EMU Pin	Debug Mode	Debug Signal Routing	EPM Control Field	EPM Control Value
jtag_emu0	Trigger	Trigger 0	DBGPO	0001

Glossary

Numerical

- 2D**— Two dimensional
- 3D**— Three dimensional
- 3GPP**— 3rd Generation Partnership Project

A

- ABS**— Absolute value
- ADC**— Analog-to-digital converter/conversion
- AEW**— Adaptive multirate
- AHB**— Advanced high-performance bus
- AMR**— Adaptive multirate; also Audio modem riser: An Intel specification that defines a new architecture for the design of motherboards.
- APB**— Advanced peripheral bus
- APE**— Applicative processor engine
- API**— Application programming interface; also ARM port interface
- ARAU**— Auxiliary register arithmetic unit
- ARGB**— Alpha, red, green, blue
- ASIC**— Application-specific integrated circuit: A chip built for a specific application. In the context of this document, ASIC refers to the FPGA that resides on the EVM board.
- ASCII**— American standard code for information
- ATR**— Answer to reset
- AVC**— Advanced video coding (MPEG4 - Part 10 also known as H264)
- AXI**— Advanced extensible interface

B

- BB**— Busy bus
- BCD**— Binary-coded decimal: A representation of decimal digits (0–9) using a nibble that uses a certain number of bits. For example, using 4 bits, two BCDs can be packed into 1 byte.
- BGA**— Ball grid array
- BGAPTS**— Band gap voltage and temperature sensor
- BGT**— Block guard time

Appendix A

www.ti.com

BIOS— Built-in operating system

BIST— Built-in self-test

Bluetooth®— A short-range radio technology designed to simplify communications among network devices and between devices and the Internet. It also simplifies data synchronization between network devices and other computers.

BPP— Bits per pixel

BTA— Bus turn around

C

CALU— Central arithmetic logic unit

CAVLC— Context-adaptive variable length coder

CAVLD— Context-adaptive variable length decoder

CBUFF— Circular buffer

CDL— Controlled delay line

CE— Chip enable

CH— Configuration header. To use settings other than ROM code defaults, (that is, clock frequencies, SDRAM/DDRAM settings, or GPMC settings).

CID— Card identification number

CIF— Common intermediate format. A video format used in video conferencing systems that easily supports both NTSC and PAL signals. CIF is part of the ITU H.261 video conferencing standard. It specifies a data rate of 30 fps, with each frame containing 288 lines and 352 pixels per line.

CLE— Command latch enable

CLK— Clock

CLUT— Color look-up table

CMOS— Complementary metal oxide semiconductor

CMT— Cellular mobile telephone

Codec— Coder/decoder or compression/decompression: A device that codes in one direction of transmission and decodes in another direction of transmission.

ConnID— Connection identifier: An initiator module identifier. A ConnID transmitted in-band with the request and is used for protection and error logging mechanism.

CP15— Coprocessor 15: This coprocessor controls the operation and configuration of the TI925T.

CPSR— Current program status register

CPU— Central processing unit: The CPU is the portion of the processor involved in arithmetic, shifting, and Boolean logic operations, as well as the generation of data and program memory addresses. The CPU includes the CALU, the multiplier, and the ARAU.

CRC— Cyclic redundancy check

CS— Chip-select

CTRL— Control

CVBS— Composite video broadcast signal

CWT— Command wire tracer

D

D2D— Die-to-die

DAC— Digital-to-analog converter

DBB— Digital baseband

DBI— Display date interface

DCS— Display command set

DCO— Digitally controlled oscillator

DCT— Discrete cosine transform: A fast Fourier transform used to manipulate compressed still and moving picture data.

DDR— Dual data rate

DE— Date enable

DFF— Digital flip-flop

DFT— Design for test

DI— Data identifier

DISPC— Display controller

DLL— Delay-locked loop

DMA— Direct memory access: A mechanism whereby a device other than the host processor contends for and receives mastery of the memory bus so that data transfers can occur independent of the host.

DMC— Data memory controller

DPD, DPDM— Deep power-down mode

DPF— Dynamic power framework

DPI— Display parallel interface. Digital implementation of PLL

DPLL— Digital phase-locked loop

DRD— Dual role device

DRDY— Data ready

DRM— Digital rights management

DSI— Display serial interface

DSP— Digital signal processor: A semiconductor that manipulates discrete or discontinuous electrical impulses in a manner that implements a desired algorithm.

DSS— Display subsystem

DT— Data type

DVFS— Dynamic voltage and frequency scaling

E

EAV— End of active video

Appendix A

www.ti.com

- ECC**— Error checking and correction; also error correction code.
- ED**— Endpoint descriptor
- EDC**— Error detection code
- eFuse**— Electrical fuse: A one-time programmable memory location usually set at the factory
- EHCI**— Enhanced host controller interface
- EMC**— External memory controller
- EMI**— Electromagnetic interference
- EMV**— Initial letters of Europay, MasterCard, and VISA, the three companies which originally cooperated to develop the EMV standard
- EOF**— End of frame
- EOT**— End of transfer
- ES**— Erase status
- ETB**— Embedded trace buffer
- ETSI**— European Telecommunications Standard Institute
- ETM**— Embedded trace macrocell

F

- FC**— Frame counter
- FE**— Framing error: An error that occurs when the asynchronous serial port receives a data character that does not have a valid stop-bit.
- FIFO**— First in first out: A queue; a data structure or hardware buffer from which items are removed in the same order they were put in. A FIFO is useful for buffering a stream of data between a sender and receiver which are not synchronized; that is, the sender and receiver are not sending and receiving at exactly the same rate. If the rates differ by too much in one direction for too long, the FIFO becomes either full (blocking the sender) or empty (blocking the receiver).
- FIQ**— Fast interrupt request
- FlatLink™ 3G**— A Texas Instruments display interface protocol
- FS**— Frame synchronization
- FSM**— Finite state-machine: A model of computation consisting of a set of states, a start state, an input alphabet, and a transition function that maps input symbols and current states to a next state.
- FSR**— Fault status register
- FT**— Feed through

G

- GDD**— Generic distributed DMA
- GP device**— General-purpose device
- GPIO**— General-purpose input/output: Pins that can accept input signals and/or send output signals but are not linked to specific uses.
- GPMC**— General-purpose memory controller
- GSM**— Global system for mobile communications

H

- HC**— Host controller
- HDTV**— High-definition television
- HFP**— Horizontal Front Porch
- HNP**— Host Negotiation Protocol
- HPI**— Host port interface
- HS**— High speed
- HSEC**— Horizontal sync end code
- HSSC**— Horizontal sync start code
- HSYNC**— Horizontal synchronization: A bidirectional horizontal timing signal occurring once per line with a pulse width defined as an integral number of FCLK periods. Synchronization signals can be used to enable retrace of the electron beam of a display screen. Also HS.
- HSW**— Horizontal Synchronization Pulse Width
- HVGA**— Half-size video graphics array. One-half the resolution of VGA
- HW, H/W**— Hardware
- HWA**— Hardware accelerators

I

- I²C**— Inter-integrated circuit: A multimaster bus where multiple chips can be connected. Each chip can act as a master by initiating a data transfer.
- I²S**— Inter-IC sound: A digital audio interface standard.
- IA**— Initiator agent, also Identifier address
- IC**— Integrated circuit
- ICR**— Intersystem communication registers
- IF**— Interface
- INT**— Interrupt: A signal sent by hardware or software to a processor requesting attention. An interrupt tells the processor to suspend its current operation, save the current task status, and perform a particular set of instructions. Interrupts communicate with the operating system and prioritize tasks to be performed.
- INTC**— Interrupt controller
- I/O**— Input/output
- IP**— Intellectual property
- IPC**— Interprocessor communication. Also referred to as *mailbox*.
- IrDA**— Infrared Data Association: Represents the group of device manufacturers that developed a standard for transmitting data via infrared light waves.
- IRQ**— Interrupt request: IRQs are hardware lines over which devices can send interrupt signals to the microprocessor.

Appendix A

www.ti.com

ISO— Isochronous: This refers to processes where data must be delivered within certain time constraints. For example, multimedia streams require an isochronous transport mechanism to ensure that data is delivered as fast as it is displayed and to ensure that the audio is synchronized with the video. Also, *International Standards Organization*.

ISP— Image sensing product; also image signal processor

ISR— Interrupt service routine: A function or set of functions that are called when an interrupt is encountered.

ITU— International Telecommunications Union

IVA— Image and video accelerator

J

JPEG— Joint Photographic Experts Group

JTAG— Joint Test Action Group: The JTAG was formed in 1985 to develop economical test methodologies for systems designed around complex integrated circuits and assembled with surface-mount technologies. The group drafted a standard that was subsequently adopted by IEEE as IEEE Standard 1149.1-1990, IEEE Standard Test Access Port, and Boundary-Scan Architecture.

K

Kb— Kilobits

KB— Kilobyte, 1024 B

Kbps— Kilobits per second

L

L1— Level 1 cache/memory

L2— Level 2 cache/memory

L3— First level of interconnect in platform

L4— Second level of interconnect in AM/DM37x platform

LCD— Liquid crystal display: A display that uses two sheets of polarizing material with a liquid crystal solution between them.

LCh— Logical DMA channel

LDM— Load multiple

LDO— Low dropout

LH— Local host

LINK— Link layer device

LLP— Low-level protocol

LP— Low power, operation mode for PHY

LPDDR— Low-power, double-data rate (SDRAM)

LPM— Low-power mode

LPP— Lines per panel

LPSDR— Low-power, single-data rate (SDRAM)

- LRC**— Longitudinal redundancy check
- LRU**— Least recently used
- LS**— Level shifter; also low speed
- LSB**— Least-significant bit
- LUT**— Look-up table
- LVDS**— Low-voltage differential signaling

M

- Mailbox**— See *IPC*
- Mb**— Megabit
- Mbps**— Megabits per second
- McBSP**— Multichannel buffered serial port: An enhanced buffered serial port that includes the following standard features: buffered data registers, full duplex communication, and independent clocking and framing for receive and transmit. In addition, the McBSP includes the following enhanced features: internal programmable clock and frame generation, multichannel mode, and general-purpose I/O.
- MCSPI**— Multichannel serial port interface
- MCP**— Multi-chip package
- MCU**— Microcontroller unit (refers to the MPU)
- DDR**— Mobile double-data-rate SDRAM, dedicated to mobile applications
- MIPI®**— Mobile industry processor interface
- MMC**— Multimedia card
- MMC/SD**— Multimedia card/secure data
- MMU**— Memory management unit: The MMU performs virtual-to-physical address translations, performs access permission checks for access to the system memory, and provides the flexibility and protection required for the OS to manage a shared physical memory space between the two processors.
- MPEG**— Motion Pictures Expert Group: A compression scheme for full-motion video.
- MPEG1**— The first MPEG compression scheme specification
- MPEG4**— The most current MPEG compression scheme specification, intended for very narrow bandwidths.
- MPU**— Microprocessor unit
- MS**— Mobile station
- MSB**— Most-significant bit: The highest order bit in a word. The plural form (MSBs) refers to a specified number of high-order bits, beginning with the highest order bit and counting to the right. For example, the 8 MSBs of a 16-bit value are bits 15 through 8.
- MUX**— Multiplex/multiplexer
- Muxed pin**— A pin is muxed when its pin control register field can be reconfigured by software to change the function associated with the pin.

Appendix A

www.ti.com

MuxMode— A 3-bit field of the pin control register field which enables to change the mode. Mode programming is assumed by software and selects a function on the device external interface.

N

N/A— Not applicable

NAK— Not acknowledged

NAND— NAND flash memory that is a high-capacity, low-cost, embedded, permanent data storage solution

NF— Noise filter

NMI— Nonmaskable interrupt: An interrupt that cannot be masked or disabled.

NOP— No operation (DSP/CPU instruction)

NR— Noise reduction

NSC— National Semiconductor Corporation

NTSC— National Television System Committee (television broadcast system)

O

OCM— On-chip memory

OCO— One change only

OCP— Open-core protocol

OCPI— Open-core protocol interface

OEM— Original equipment manufacturer

OGL— Open GL (programming API) enable

OHCI— Open host controller interface: This is an industry standard USB host controller interface.

OMAP— An open software and hardware platform targeted at second- and third-generation cellular phones with multimedia capabilities.

OneNand™— A memory chip based on NAND architecture integrating SRAM buffers and NOR logic interface. It combines the advanced data storage function of NAND flash with fast read speed function of NOR flash.

OTG— On-the-go (USB 2.0 specification)

P

PBIAS— PMOS bias transistor to provide the bias voltage to extended drain I/Os

PCB— Printed circuit board

PCLK— Pixel clock

PCM— Pulse code modulation: A technique for digitizing speech by sampling the sound waves and converting each sample into a binary number.

PDA— Personal digital assistant

PDE— Personal down enable

PE— Packet end

PF— Packet footer

- PH**— Packet header
- PG**— Protection group
- PGA**— Pin grid array
- PHY**— Physical layer device
- PI**— Packet identifier
- PID**— Protocol identifier: The PID register is used in Windows CE mode only.
- PLD**— Programmable logic device
- PLL**— Phase-locked loop: A closed loop frequency control system whose function is based on the phase-sensitive detection of the phase difference between the input signal and the output signal of the controlled oscillator (CO).
- PMC**— Program memory controller
- POP**— Package-on-package technology
- PMP**— Power management port
- POR**— Power-on reset
- PPI**— Physical layer protocol interface
- PPS**— Protocol and parameter selection
- PRCM**— Power, reset, and clock management
- PRM**— Power and reset manager
- PS**— Packet start
- PSA**— Parallel signature analyzer
- PT**— Packet type
- PVT**— Process, voltage, and temperature (that is, PVT dispersion)
- PWB**— Printed wiring board
- PWM**— Pulse width modulation
- PWR**— Power

Q

- QCIF**— Quarter common intermediate format: A video conferencing format that specifies data rates of 30 fps, with each frame containing 144 lines and 176 pixels per line. This is one-fourth the resolution of CIF. QCIF support is required by the ITU H.261 video conferencing standard.
- QVGA**— Quarter video graphics array (one-fourth the resolution of VGA).

R

- R**— Read only
- RBL**— Read buffer logic
- RFBI**— Remote frame buffer interface
- RFU**— Reserved for future use
- RGB**— Red, green, blue

Appendix A

www.ti.com

RGBA— Red, green, blue, alpha

ROM— Read only memory: A semiconductor storage element containing permanent data that cannot be changed.

RST— Reset

RT— Real-time

RVLC— Reversible variable length coder

RVLD— Reversible variable length decoder

R/W— Read/write

RX— Receive/receiver

S

S3220— Abbreviation of Sonics3220. It refers to the L4 interconnect.

SAM— Shared access mode: The mode that allows both the DSP and the host to access host port interface (HPI) memory. In this mode, asynchronous host accesses are synchronized internally, and, in case of conflict, the host has access priority and the DSP waits one cycle.

SAR— Save and restore: Hardware context saving for power saving

SAV— Start of active video

SCCB— Serial camera control interface: 3-wire and 2-wire serial bus defined and deployed by Omnivision Technologies, Inc.

SCL— Serial clock: Programmable serial clock used in the I²C interface. Also SCLK.

SCM— Scan combiner module; also statistic collection module

SCP— Serial configuration port

SD— Starting delimiter

SDA— Serial data: Serial data bus in the I²C interface.

SDI— Serial display interface

SDIO— Secure digital input/output

sDMA— System direct memory access

SDR— Single data rate

SDRC— SDRAM controller

SDRAM— Synchronous dynamic random access memory

SDTI— System debug trace interface

SDTV— Standard digital television

SGX— Abbreviation for graphic accelerator (GFX in ES1.0)

SIM— Subscriber identity module

SIMD— Single instruction multiple data

SILVS— Scalable low-voltage signaling

SMS— SDRAM memory scheduler

- SMX**— Abbreviation of SonicsMX. It refers to the L3 interconnect.
- SNR**— Signal-to-noise ratio
- SOF**— Start of frame
- SOT**— Start of transmission
- SRAM**— Static random access memory. Fast memory that does not require refreshing, as DRAM does. It is more expensive than DRAM, though, and is not available in as high a density as DRAM.
- SRG**— Sample rate generator
- SRP**— Session request protocol
- SRRP**— Session RAM restoration pointer
- SS**— Subsystem
- SSR**— Serial synchronous receiver
- SST**— Serial synchronous transmitter
- ST**— Start timer
- STM**— Synchronous transfer mode; also store multiple
- STN**— Super-Twist Nematic: A technique for improving LCD display screens by twisting light rays.
- SVGA**— Super video graphic adapter
- SW**— Software
- SWI**— Software interrupt

T

- TC**— Traffic controller. Allows asynchronous operation among the external memory interface, the MPU, and the DSP.
- TCK**— Test clock
- TD**— Transfer descriptor
- TDM**— Time division multiplex/multiplexing: The process by which a single serial bus is shared by multiple devices with each device taking turns to communicate on the bus. The total number of time slots (channels) depends on the number of devices connected. During a time slot, a given device may talk to any combination of devices on the bus.
- TFT**— Thin film transistor. A type of LCD flat panel display screen in which each pixel is controlled by one to four transistors.
- TLB**— Translation lookaside buffer: A cache that contains entries for virtual-to-physical address translation and access permission checking.
- TLL**— Transceiverless link: This is logic that lets the user connect two USB transceiver interfaces together directly without the use of differential transceivers.
- TM**— Target module: A target module cannot generate read/write requests to the chip interconnects, but it responds to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).
- TOC**— Table of contents
- TRM**— Technical reference manual
- TRX**— USB transceiver: The USB analog driver/receiver.

Appendix A

www.ti.com

TTB— Translation table base: It points to the base of a table in physical memory that contains section and page table descriptors.

TWL— Table walking logic

TX— Transmit/transmitter

U

UART— Universal asynchronous receiver/transmitter: Another name for the asynchronous serial port.

UICC— Universal integrated circuit card

ULPM— Ultra-low power mode

ULPI— UTMI+ low pincount interface

ULPS— Ultra-low power state

UMC— United memory controller

UNP— Unpredictable

USAR— Universal synchronous/asynchronous receiver

USART— Universal synchronous/asynchronous receiver/transmitter

USB— Universal serial bus: An external bus standard that supports data transfer rates of 12M bps (12 million bits per second). A single USB port can be used to connect up to 127 peripheral devices.

UTMI— USB 2.0 transceiver macrocell interface

UTMI+— UTMI extension supporting USB host and on-the-go

V

VA— Volt-amps: A form of power management. A VA rating is the volts rating multiplied by the amps (current) rating, used to indicate the output capacity of an uninterruptible power supply (UPS) or other power source.

VC— Virtual channel

VENC— Video encoder

VESA— Video Electronics Standards Association

VFP— Vertical front porch

VGA— Video graphics array: An industry standard for video cards.

VLC— Variable length decoder

VLD— Variable length coder

VMODE— Bi-level voltage control interface

VPBE— Video processing back end

VSEC— Vertical synchronization end code

VSSC— Vertical synchronization start code

VSYNC, VS— Vertical synchronization: A bidirectional vertical timing signal occurring once per frame with a pulse-width defined as an integral number of lines (half-lines for interlaced mode).

W

WBL— Write buffer logic

WC— Word count

WD— Watchdog: A timer that requires the user program or OS periodically write to the count register before the counter underflows.

WDT— Watchdog timer

WLAN— Wireless local area network

WMV— Windows media video

WMA— Windows media audio

Word16— 16-bit word

Word32— 32-bit word

WP— Write protect

WSS— Wide-screen signaling

WWT— Work waiting time

X

XGA, XVGA— Extended graphics array

XIP— Execution in place

Y

YUV— Luminance-Bandwidth-Chrominance

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
